If this view is correct surgeons are amply justified, since Rose, Keen, and others have shown the way, in attacking this obstinate affection in its head centre, which in this case is the Gasserian ganglion. There is nothing irrational, although there may be something theoretical in this view. I hope that in this particular case there will be a thorough microscopical study made of the condition of the Gasserian ganglion.

There are a few of these cases, which undoubtedly do well without surgical interference. It may be that the recovery is only temporary and that in time to come such cases will have a recurrence. I have had under observation for several years a lady who has had excruciating neuralgia of the inferior dental nerve at the point where it emerges from the mental foramen. The last attack continued for nine months. The pain was almost strictly isolated to the distribution of the nerve on the chin. In addition, however, there were occasional shooting pains through the lingual or gustatory nerve. This is an important point in connection with the pathology. It indicates that the affection was not peripheral. The lingual and inferior dental nerves are branches of the inferior maxillary branch of the fifth nerve. They emerge almost together from the Gasserian ganglion, but afterward have little mutual relation. The supposition, therefore, in such a case is that there was a central origin of the pain. In that case operation was considered, but not recommended. I was gratified to find that in this case expectant treatment, although long continued and including a trip to Florida, brought the suffering to a point where it could be borne with patience. Whether or not it will return and attack other nerve trunks remain to be seen.

DR. WHARTON SINKLER: When we come to consider the pathology trigeminal neuralgia, there is a great deal that might be said.

I am not prepared to accept fully Dr. Lloyd's view that the origin of the disease is to be found in the ganglion, for one sees many cases in which the neuralgia is to be traced directly to some peripheral irritation. It also seems scarcely probable that if the disease were always central excision of the nerve would be followed by relief lasting for several years, as is often the case.

The tendency toward surgical interference in neuralgia of the fifth nerve has increased very much of late years, Dr. J. J. Putnam expressed the opinion in a recent paper, that it is not worth while to attempt medicinal measures in these cases, but urges the excision of the nerve as far back as possible be at once resorted to. Dr. Keen goes further and makes the suggestion that it may be desirable to begin at once with the removal of the ganglion. It seems to me that these measures are too radical. We know that in excision the ultimate results are far from satisfactory, and like the relief from nerve-stretching, it is of brief duration. In the case of the operation for removal of the Gasserian ganglion, we do not know how permanent the relief may be. In all of the five cases operated on by Rose there was relief up to the time that the cases were reported, but the longest time after operation in any case was only twenty-two months, and in one of the cases the operation had been done only sixteen days. Then we must consider the mortality which follows the operation. According to the statistics given by Dr. Keen, forty cases have been operated on with six deaths, a death rate of fifteen per cent., which is a rather formidable mortality in a disease which does not threaten life. It therefore seems to me that before resorting to operative procedures we should use other remedies. There are certainly many cases that are relieved by medicinal means—that is, by the administration of drugs and the use of galvanism. I have now under my care an old lady over eighty years of age, who for the past five or six years has suffered from the most violent attacks of tic douloureux, and who is most invariably relieved by gelsemium pushed to physiological doses. Of course, when drugs fail, we must be thankful for having the opportunity to resort to an operation which has given such complete relief as excision of the Gasserian ganglion. I notice by the way, that Horsely questions very much whether the entire ganglion has ever been removed. He doubts if this be possible.

DR. FRANCIS X. DERCUM. I have little to add to what has already been said. I think that in these cases we should be guided rather by what we know of the pathology. While Dr. Lloyd's speculations are interesting, I hardly think that we can allow them to guide us in the choice of so radical an operation which is not without some danger.

It is certain that in some of these cases, at least, there is inflammation present in the nerve trunk itself. I know of at least four cases in which the microscope shows actual lesion in the nerve trunk to account for the pain. In one case where the infra-orbital and the inferior maxillary nerves were re-

moved, complete relief was afforded until the death of the patient some years later.

With regard to medicinal measures, I think that a definite plan should be pursued. We should in these cases search for diathetic troubles. In some cases we find the rheumatic diathesis, and even if it is not present, a short course of the salicylates will do no harm. I have seen the salicylates in full doses give great relief, so great that the patient would be without pain for months. It has occured to me that we might also make use of piperazin, which in chronic form of nerve trouble is often of extreme value. In fact, some of the principles that guide us in the use of drugs in the treatment of sciatica should guide us in the treatment of this trouble, which is far oftener a neuritis than we are apt to think.

With regard to the possibility of excising the entire ganglion. It seems to me that it is possible to destroy the great bulk of the ganglion—at least, the posterior two-thirds. Whether or not the part supplying the ophthalmic region was touched in this case, I cannot say,

DR. JOHN B. ROBERTS; I am interested in the fact that the mass of gauze did not produce any great amount of disturbance. This only enforces what I have had long on my mind, that what we usually call compression of the brain is probably nearly always inflammation. We can have a good deal inside of the skull, such as bone or clot, with a very few symptoms, if sepsis be excluded. I do not believe much in compression of the brain after fracture, but think that the symptoms are nearly always due to inflammation the result of the irritation and probably a septic irritation of the brain tissues, That may not be neurologically correct, but it has stood me in good stead surgically as a clinical experience.

The elaborate engine shown, seems to work very satisfactorily. For my work, however, I would rather use a sharp chisel and a mallet with my hands, than any mechanical device.

These are apt to get out of order and must be kept in a place such as a hospital where they can be readily put in repair. What we want to do is to train our hands to do the work and not be dependent upon any mechanical device. The patient whom I shall show was operated on for intra-cranial neurectomy with great satisfaction with a small chisel, not the ordinary chisel for operating on the large bones, but such as we would use for delicate work, and one having the shape of a small osteotome. The chisel should be very sharp and the corner of it should be used for cutting the groove in the bone. I am getting into the habit of using the chisel rather than the trephine and am coming to think that the trephine is a little oldfashioned.

This is the man whose case I reported a year ago, and showed the second and third divisions of the fifth nerve, which I had excised in front of the Gasserian ganglion for tic douloureux. The man had had neuralgia for many years and had been operated on peripherally many times with relief for six or ten months, or even a year or two. I ligated the carotid artery, giving relief for a year; but the pain returned, and a year ago last December I did the intra-cranial operation, making the osteoplastic resection of Hartley, removed the second and third divisions of the nerve back to the Gasserian ganglion, but did not get out the ganglion. He has been absolutely comfortable for the last fourteen months. This man had no inflammation of the eye following the operation. I stitched the lids together before opening the skull. The nerves removed have been submitted to a pathologist, but so far I have had no report.

Here is another man on whom I have done a different operation for the same affection. He had intense neuralgia of the infra-orbital. I excised the nerve and he had comfort for two years. Two and a half months ago he came back saying that the pain had returned. Not thinking it proper to at once go into the interior of the cranium, I resected the ganglion of Meckel. I made an inverted V-shaped incision over the zygoma, familiar to all surgeons, sawed the zygoma in two places, turned down the musculo-osseous flap, and sought for the ganglion in the pterygo-maxillary fossa. I did not recognize the ganglion, but tore out what was in its vicinity. The internal maxillary artery was divided in the operation. The patient has comfort now, but it is only two months since the operation.

In another case ligation of the carotid afforded relief for a number of months, but then the pain returned. It seems to me, therefore, that the proper method is to begin peripherally excising the painfnl nerves and to repeat the operation as the pain returns until we finally get back to the ganglion of Gasser.

DR. BRUCE BURNS: I certainly believe that Dr. Lloyd is right, that in a certain number of these cases the affection is due to changes in the ganglion. In selecting the treatment of these cases a great deal of differentiation is required. There may be some cases arising from the periphery as the result of neuritis, neuroma, exotosis, etc. I have had some experience in operating on these cases. While the immediate results have been satisfactory, the results as regards ultimate recovery have not been good. One case was that of a lady sixty-five years of age, who had suffered from severe neuralgia for over thirty years, most of the time being con-

fined to bed. She had become an opium-eater and relied on large doses of whiskey or brandy for temporary relief. The teeth had long ago been extracted. After watching the case and knowing that medical measures had been given a thorough trial, I advised operation. In that case I trephined the superior maxillary and removed an inch and a half of the infra-orbital nerve; I also resected the inferior dental nerve in its whole length. Relief followed and continued for about two years. The pain returned and the general condition was so bad that I hardly thought it advisable to recommend further operation. The patient insisted that something be done, and I finally determined to attempt the removal of the superior maxillary bone. Before the operation was concluded the shock became so extreme that I desisted and the patient died shortly afterward.

Within the last twelve months I have had another case which I think is of ganglionic origin. There I removed the infra-orbital and the inferior dental. This gave a great deal of relief until a few weeks ago, when after exposure to cold there was a return of the trouble.

As I said before, I believe that in our treatment we should differentiate between the cases that are of peripheral and those that are of ganglionic origin.

DR. EDWARD JACKSON: In describing the operation, reference was made to the obstacle of bleeding at two separate stages; one due to rupture of a branch of the anterior meningeal artery was promptly controlled, and the other occurred on raising the brain, was not clearly accounted for, and caused the suspension of the operation. In conversation, Dr. E. W. Stevens has mentioned to me a point in anatomy that throws light upon this. In the dissecting-room his attention has this winter been directed toward this operation, and he has almost constantly found two veins of considerable size entering the bone at this point, so that they would necessarily be torn in the separation of the brain from the floor of the skull in order to get sufficient room to reach the ganglion.

THE PRESIDENT, DR. WILLARD: Having had occasion in the last few months to look up this subject, and as the operation of Rose has not been described to night, it may be of interest to show diagrams illustrating Rose's operation. This operator cuts through the zygoma, saws off and turns back the coronoid process, and ligates the internal maxillary artery. He then reaches the foramen ovale and applies a trephine directly beside the nerve and then through this opening removes the ganglion with a curved hook. This route will probably be selected by surgeons unaccustomed to intra-cranial work.

Rose reports 7 cases with only 1 death from meningitis, and Andrews 4 with 1 death. In a collection of 40 cases which I have made, there were 6 deaths. These cases represent results obtained both by the Rose and by the Hartley or Krause method.

With regard to the removal of the entire ganglion, it has been almost the universal experience of operators, either through the spheno-maxillary fossa or within the cranium, that while they have believed that they have excised the ganglion, they have not been at all certain that the entire mass was removed.

DR. KEEN: I regret that I was prevented from arriving till so late that I am not able to take part in the discussion. I wish, however, to show the electric lamp to which reference has been made. The lamp is that made by Hirschman, of Berlin. The storage battery is made by Mr. Fleming, of this city. The battery has ten cells and is provided with two rheostats, so that with one I can use the electric light or galvanic current. The other can be used for galvano-caustic purposes. In the lid is a large compartment in which the lamp, etc., may be carried.

DR. MITCHELL: As to the origin of this affection, it seems probable that in many of these cases the origin is not central. This point was discussed in the paper. While such an origin is possible, I do not believe that it is always or commonly the case. If the disease originated in the ganglion, operations on the peripheral nerves would not give the relief that we find to follow in many of these cases.

# THE LIBRARY TABLE.

## BOOK REVIEWS.

*Antiseptic Therapeutics*, E. Trouessart, translated by E. P. Hurd, 2 vols., constituting part of the Physicians' Leisure Hour Library, published by Geo. S. Davis, Detroit; 25 cents for single numbers; $2.50 per annum.

The first volume discusses the antiseptic and toxic powers of inorganic and organic chemicals; the second volume is classified by diseases, ending with an abridgement of the author's third part on antiseptics in hygiene and nursing. Antiseptics are made to include not only substances ordinarily so considered, but remedies which neutralize toxines, whether produced by a bacterium, a fungus, or even by perverted cells of the body, as in rheumatism and gout. Some excellent generalizations are made as to the relation between antiseptic power and chemical constitution. We are told that "The group naphtyl, $C_{10}H_7$, is about twice as antiseptic as the group phenyl, $C_6H_5$, and the latter is five or six times more energetic than the group methyl, $CH_3$."

We are pleased to note that the metric system is used, with few exceptions. A number of inaccuracies detract from the value of the work for ready reference, although they are mainly self-correcting if the books are carefully read. The work is a little disappointing, not from any fault of the author or translator, but on account of the present lack of precise information. Its special value is to present facts already known in a new light and to stimulate further experimentation with internal antiseptics.

*How to Use the Forceps*, with an introductory account of the Female Pelvis and of the Mechanism of Delivery, by Henry G. Landis. A.M., M.D., Professor of Obstetrics and Diseases of Women and Children in Starling Medical College, Columbus, O. Revised and enlarged by Charles H. Bushong, M.D., Assistant Gynæcologist and Pathologist to Demilt Dispensary, New York. Illustrated. New York: E. B. Treat, publisher, 5 Cooper Union. 1894. pp. 203. Price, $1.75.

This book contains a very clear and concise account of the pelvic canal, from the standpoint of the obstetrician, as well as the method in which the fetal head passes through it. The criticism to be made is rather on what has been left out than what has been said.

For instance, concerning the question, Why does internal rotation occur especially in posterior positions?, the author makes no mention of the pelvic soft parts, but assigns the cause to inclined planes of the bony canal, torsion of the neck, etc. Now it is generally admitted that the chief factor in internal rotation is the resistance of the soft parts to the most advanced part of the fetal head, and the most important component of the soft parts is the levator ani muscle. Much importance is given to *the perineal body* as a force in labor, and the author states that "the muscles attached to *the fibrous perineal body* should be considered as a part of it when describing it." However, the following sentence will disclose the lack of his appreciation of the function of the levator ani muscle: "As the head escapes from the vulvar orifice the perineal tissues retract to nearly their original condition, chiefly by *reason of their inherent elasticity, aided somewhat by the action of the transverse muscles of the perineum.*"

Concerning the kind of forceps to be used the author expresses his preference for the Davis forceps. He finds this, *properly used*, all sufficient for traction in the axis of the birth canal. He alludes to the Tarnier forceps as "an unnecessarily ingenious contrivance." The fact that the latter admit of natural internal rotation and flexion and extension while traction is being made, does not seem to have outweighed the other in usefulness in his estimation. As to anæsthetics when using the forceps, the author says, "the use of anæsthetics is neither necessary nor advisable."

The book is a very instructive one, and will amply repay careful study on the part of any one who is interested in this branch of medicine.

*Lehrbuch der Fracturen und Luxationen, fuer Aerzte und Studierende.* Bearbeiet von Dr. Albert Hoffa, Privat-docent der Chirurgie an der Universitaet Wuerzburg. Second augmented and improved edition, with 395 illustrations in the text and 29 colored plates. 705 pp. Stahel'sche Hof-und Universitaets-Buchhund Kunst-Handlung. Wuerzburg.

This eminently practical work on fractures and luxations is written by one who is well known in surgery, and especially in orthopœdic work. It is intended to present a clear and practical exposition of the subject to both student and practitioner, and to present this subject in the present condition of surgery. Therefore has attention not only been paid to pathological anatomy, but also to differential diagnosis and therapeutics of the various conditions, so that with simple means one may obtain good results. Of the various means of bandaging and dressing only those have been included which have stood the test of time and experience. In order that one may have a clear idea of the subject there are incorporated, in the text, numerous illustrations, with a series of colored plates, at the end. In the explanations he has sought to present all the relations which might assist dislocation of the fragments and to bring forward types which, once seen, the deviations may be easily noticed. The consideration of each subject is full and quite complete, and well up with the advances in this branch of medicine. The second edition has undergone many improvements and much elaboration. Above all, the writer has sought to include recent advances with regard to both the German and foreign literature. The new methods of treatment have been tried on the material under his care, as much as possible, and that incorporated which has been found practical. The rarer fractures and luxations are rendered

clearer and more easily comprehended by including histories of cases and pathologico-anatomically well analyzed cases, in the text, together with a number of new figures. It has met with a favorable reception in Germany.

*The Year-Book of Treatment for* 1894, A comprehensive and Critical Review for Practitioners of Medicine and Surgery. In a series of twenty-four chapters, by eminent specialists. In one 12mo. volume of 497 pages. Cloth, $1.50. Philadelphia, Lea Brothers & Co., 1894.

In the ten years of its publication, The Year-Book of Treatment has firmly established itself as an invaluable aid for all those who desire to keep posted on the current additions to the world's knowledge of the management of disease. The word "treatment" is construed in its broadest sense, including medicine, surgery, gynecology, obstetrics, pædiatrics, and all the specialties, in a series of twenty-four chapters, each contributed by a gentleman eminent in his assigned subject. Bacteriology and hygiene are compendiously dealt with, and the Summary of Therapeutics for the year presents this most important subject in the most available form for use. The various articles are sufficiently detailed for all practical purposes, but references to original papers are given for the convenience of those desiring to make extended research.

The volume contains a "Selected List of New Books, New Editions and Translations," which will give the reader a knowledge of the latest and best literature under each head. The Index of Authors Quoted, and Index of Subjects, complete and close a volume which is authoritative, well arranged, serviceable for every medical man, and universally available, owing to its very moderate price.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

## ARCHIVES OF PEDIATRICS.

In the March number, Dr. A. Brothers continues an article on the

**Treatment of Empyema in Early Life,**

giving an historical review of the methods that have been resorted to.

Operations he classifies under the heads of puncture and methods by the knife.

This article covers the subject very completely, giving as concisely as possible the differences in the operations practiced by different men, and finally the author concludes with his own experience, and his reasons for preferring incision to puncture with the aspirator.

Puncture with the aspirator the author thinks useful to temporarily relieve a case, until the system can be built up and incision made.

In children, section of ribs is rarely called for, unless the case is one of long standing. In adults, however, the case is different, and it is usually necessary to divide one or more ribs to insure the closure of the cavity. As soon as pus is diagnosed, the author declares the only treatment to be prompt and free incision with drainage.

Dr. George Carpenter writes of the

**Incubation Period of Scarlatina, etc.**

Most authors, he states, declare the incubation to be from two to eight days, but the writer quotes cases which seem to show that it may range from two days to three weeks. This should lead to a longer period of quarantine of those convalescing from this disease than is at present demanded by law. The author emphasizes the fact that so long as desquamation is taking place, whether in the scalp or elsewhere, the patient is capable of acting as an infecting centre to others.

whiskey, in diphtheria. The drug has sev-

Dr. Talbot R. Chambers gives his experience with tincture of nux, as a substitute for eral advantages and was used in dose sufficient to sustain the pulse, etc., in about its normal condition.

In the first case mentioned the required dose was one minim every half hour at first, and less frequently later on.

Dr. D. J. Milton Miller writes of the value of alkalies and aromatics in digestive disorders of children.

In the condition known as mucous disease, due to improper feeding, the author states that combination of these two classes of drugs acts by the solvent and antacid power of the alkalies, and the power aromatics have of dissipating pain and spasm. Alkalies also, when diluted and given on an empty stomach, appear to stimulate the secretion of gastric juice. The author describes some typical cases and his treatment of them. Besides restricting the amount of farinaceous food, he administered soda bicarb., sp. ammonii aromat., glycerin and aqua mentha, with or without sp. chloroform, and tr. capsicum.

---

## JOURNAL OF CUTANEOUS AND GENITO-URINARY DISEASES.

Dr. John T. Bowen, reports a case of

**Hydroa Vacciniformis**

the first, he believes reported in America. The patient was a white boy, and without important family history. Since five years of age, the boy has had after exposures to the sun, repeated attacks of this trouble, more frequent in Summer. He has never been free for more than two months at a time, even in the winter season.

Of late a few lesion appeared on the hands, also, but usually the face alone was affected. Sometimes an attack was ushered in with malaise and vomiting; sometimes not.

The patient is undersized and anæmic, with face, especially the nose and malar prominences, covered with cicatrices precisely resembling those of variola: these cease gradually at the hairline of the scalp.

The eruption consists first of red papules, which become vesicular and vesico-pustular. These may now enlarge, and sometimes present a marked umbilication surrounded by a clear or turbid fluid, which in turn is circled by an erythematous halo.

Only the most advanced lesions are umbilicated, and the centre of these presents a peculiar dark blue or black aspect, which is due not to the contents but to the floor of the lesion, and in many cases, the author states, this dark floor presents points of still darker color. The lesions may become confluent.

During the next stage the dark centre and its covering are replaced by a very adherent thick black crust, which is finally cast off, leaving a deep punched-out pit, usually circular, and at first deep red in color.

The author states there was no pigmentation, but in some places new lesions were forming in old pits. Few sores appeared on the hands, none above the wrisks, and none on any other parts of the body.

The cervical, submaxillary, and inguinal glands were enlarged but all others appeared normal.

Under the use of a carbolized zinc oxide lotion, and the internal use of iron, the case improved more rapidly than usual, but had a second attack after a short respite. Another and more severe attack came on after going out on a sunny, but very cold December day, and this time the face was much swollen at first. Itching rarely occurs in these cases, although it was a prominent symptom in this one, and the attacks grow milder as the patient grows older, until they disappear in adults.

Microscopic examination of a typical lesion shows necrosis of both epidermis and corium, reaching almost to the subcutaneous tissue, but ceasing very abruptly at both the side and bottom. Near the lesion the epidermis is thickened and the corium full of small round cells. Hair follicles and sweat glands are numerous and normal. Examination for micro-organisms gave no results of importance. Examination of a less fully developed papule showed that the trouble begins in the epidermis and upper part of the corium, and if at this point improvement does not set in the part involved and the corium immediately underneath become necrotic.

The necrotic process differs from that of variola in being secondary to the vesiculation, while in variola Weigert found necrosis to be primary.

As in all other skin diseases where umbilication appears, it seems due to the central necrotic area holding down the centre of the lesion, while the epidermis around is allowed to proliferate and form a raised border.

The treatment has not been very successful, the author says, but veils of red or turmeric colors, by neutralizing the chemical rays of the sun, would go far toward preventing the disorder.

Dr. Heumann G. Klotz writes on

**Antisepsis in the Treatment of Eczema.**

This principle, he says, now so carefully observed in general surgery, is neglected greatly in dermatology, where the conditions are generally such as to invite sepsis constantly.

The reason for this neglect, the author thinks, is due to the fact that the drug in most general use to prevent sepsis elsewhere, carbolic acid, is injurious to the skin and often seems, unless used with extreme care, to render any irritation of the skin worse. The author prefers to use weak solutions of bichloride of mercury, 1:3000 to 1:5000, preferring solutions in almost all cases to ointments, contrary to the usual teaching of dermatologists. He also has success with boric acid, sometimes uses it in ten per cent. ointment after applying a bichloride lotion for a time. The author goes on to show that almost every one of the so-called soothing lotions in popular use for a long time are of more or less antiseptic value, (even infusion of chamomile) and the ideal preparation is one which, while not strong enough to be irritating, is yet antiseptic and which will favor new skin production. The author then mentions ichthyol in 1 to 1,000 or 2 to 1,000 strength, salicylic acid, thymol, resorcin, etc., but seems to prefer a mixture of fifteen or twenty grammes of boric acid, two to five grammes acetate of lead, a half pint of lime water with enough boiled water to make a quart; sometimes adding to this a small amount of glycerine and alcohol.

Dusting powders are useful and are preferably made of boric acid, etc., with some mineral powder such as talcum, magnesia carbonate, or kaolin, rather than vegetable preparations, such as starch. Some of the plasters in common use, the author thinks ideal antiseptics, requiring only the addition of cotton or some absorbent to make them perfect.

Dr. J. H. Pooley describes a case of

**Molluscum Fibrosum,**

the subject being a man, now fifty-eight years old, who when a boy of ten years had an attack of so-called erysipelas. During convalescence the skin peeled off from face and body, and shortly afterward a number of small elevations appeared over the body. These are scattered over the head, neck and limbs, the author says, but over the back and chest are as thickly placed as possible. Microscopically they prove to be molluscum fibrosum and the only noteworthy features are their uniform size, and their apparent connection with the erysipelas. No known family history throws any light on the case.

---

THE EDINBURGH MEDICAL JOURNAL

for March contains a paper by W. G. Aitchison Robertson, M. D., on

**The Fermentation of Sugars.**

As the result of the author's investigations he presents the following practical deductions:

In cases of dyspepsia there is usually much delay in the absorption of carbohydrates, even when digested. They are consequently exceedingly prone to undergo fermentation, and this is specially apt to occur if the carbohydrate be in slight excess.

In that variety of dyspepsia accompanied by lactic fermentation, the use of those sugars which rapidly undergo the lactic change, viz., dextrose, lævulose, and invert sugar, is contra-indicated, while the moderate use of cane sugar, maltose, and lactose may be allowed.

In those cases of dyspepsia where butyric fermentasion is prominent, milk sugar would seem to be the most suitable, as it is least easily changed by ferment. On the other hand, maltose is very readily changed, as the other sugars also are to a lesser degree.

Lastly, in dyspepsia associated with the alcoholic and acetic acid fermentations, cane sugar, dextrose, maltose, and lactose may be allowed in small amounts; while invert sugar and lævulose should be forbidden. Lactose, however, is the sugar to give in this condition, as it is not at all acted on by the alcoholic ferment.

These theoretical deductions have been supported by clinical observation in the case of cane and invert sugar. The author leaves it for future investigation to show whether they are true as regards the other sugars.

F. W. N. Haultain, M. D., contributes a paper on

**Dilatation of the Cervix by Champetier De Ribes's Bag.**

The instrument simply consists in a silk bag covered by india-rubber, which, when distended, assumes the definite shape of an inverted cone, measuring at its base about 3½ inches in diameter.

For the purpose of introducing the dilator, a pair of separable forceps have been devised, which are of great value when the initial dilatation is not greater than the diameter of a quarter dollar; but when larger than this, the introduction of the bag can be most conveniently performed by means of a pair of ordinary curved vaginal forceps.

The not inconsiderable dimensions of the collapsed bag make it necessary that a certain amount of initial dilatation requires to be present before introduction can be attempted, the amount necessary being slightly larger than the diameter of a quarter dollar; or, in other words, the os requires to admit one finger fairly easily.

Before introduction the bag should be crumpled into as small a compass as possible and thoroughly oiled. It is then grasped by the application forceps and slowly pushed through the cervix till at least a half has passed the os internum.

The forceps are now loosened, and partial distention (by means of warm water pumped in by an ordinary Higginson syringe) commenced; the forceps are now withdrawn and full distention completed, this being estimated by a known number of syringefuls being necessary.

As the bag distends it becomes accommodated to the surrounding parts and adapted to the existing degree of cervical dilatation existing, its curved shape allowing it easily to lie on the axis of the pelvic brim.

From the large size of the bag, the pressure on the presenting part must necessarily be considerable, and thus tend to displacement, —a disadvantage in its use.

The bag in its shape corresponds with the normal bag of waters for which it forms a most excellent substitute, as the author has on more than one occasion proved. But as a simple substitute for the normal membranes its benefits as a dilator are by no means exhausted, because when rapid and more forcible dilatation is required it is of great service in forming a most efficient point of resistance to the finger in performing digital dilatation. Further, by making traction on the bag considerable assistance can be given to feeble uterine contractions, and even dilatation attained where they are entirely absent.

Although the main function of the instrument is as a dilator, it must undoubtedly act benefically in cases where the membranes have been long ruptured, by preventing compression of the soft parts between the presenting head and the pelvis, through forming a basis upon which the fœtal head rests. This action upon the presenting part where exaggerated, although forming one of the stated objections to the use of the bag, must be looked upon in some cases as of distinct value, as where compression of the cord is thus avoided.

The author believes that the instrument is of especial advantage in the induction of premature labor in which operation it has been extensively used in France.

As regards any special danger in using the dilator, the only one which suggests itself to his mind is the introduction of the bag in cases where after prolonged labor the lower uterine segment has become much thinned; here its introduction may be the means of causing rupture of the uterus, otherwise its employment under ordinary antiseptic precautions seems at all times safe.

Appended to the paper is the report of several cases in which the author made use of the bag.

W. Ramsay Smith M. B. describes a

**Definite Form of Skin Disease Allied to Erythema and Urticaria.**

The first time he saw the rash was on an infant six months old. The eruption, which partook of the nature of an erythema or an urticaria, was distributed pretty much all over the body, but was specially abundant in a zone round the upper part of the abdomen.

The spots were single, as a rule, although here and there some were so close as to appear confluent. The appearance of the spots raised a strong suspicion that they might be due to the bites of insects. The boy had been in the garden playing among grass, and several of the spots had a central mark closely resembling the injury inflicted by a sting or a

sharp pair of jaws. Subsequent observation convinced him that this theory was untenable. Some of the spots had no such mark, but were really wheals. The majority, however, consisted of white or very pale pink spots, varying in diameter from an eighth to half an inch, becoming red within an hour or two, and then fading away in four or five days,—other crops appearing in the meantime, and running a similar course. Some of the "spots" became hard and shotty in the skin; some, especially on the dorsal aspect of the fingers and toes, became almost warty, and remained for a week or more; and others became vesicular, and burst, exuding a clear coagulable fluid. The skin, in these cases, would take two or three weeks to assume its normal appearance. Intense itchiness of the skin, and a considerable amount of constitutional disturbance, were associated with the appearance of the rash. The attack passed off, but recurred after a few weeks, when the same train of symptoms was repeated.

The author describes five other cases of the same disease. He relies chiefly upon constitutional treatment. In children most benefit seems to arise from a smart purge of calomel. He has tried quinine in large doses at the beginning of an attack, and also antipyrine, both with some degree of temporary advantage, but he puts the most trust in the efficacy of calomel. In adults the disease is often very troublesome, and sometimes the treatment is very prolonged and the improvement very slow indeed.

This issue of the journal also contains the second of the Morrison Lectures on Insanity by John Batty Tuke, M. D. John Wylie, M. D., continues a paper on "The Disorders of Speech;" this number being devoted to the consideration of aphasia and other disturbances of speech in relation to evanescent organic affections and functional disorders of the cerebral cortex. James Ritchie, M. D., discusses "Prolapse of the Bladder during Pregnancy and Parturition," reporting a case.

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## THERAPEUTICS.

### Atropine in Morphinism.

Prof. W. Kochs, of Bonn (*Therap. Montash*).

Last year the author had occasion to treat a case of severe morphinism, in which considerable quantities of the drug had been taken, and very alarming symptoms were produced. It was necessary to directly counteract the poison; five times during ten months Prof. Kochs used, in this case, atropine with the very best results. The patient was dismissed, but returned repeatedly, falling a victim to the habit. The author states that, to his knowledge, atropine had not, until then been used in morphinism, and considers that the symptomatic antagonism of these two drugs has not been sufficiently appreciated. Many do not accept the view that atrophine is capable of contracting the action of morphine.

It is well to begin with very small doses of atropine subcutaneously (0.0002 gme. [1-333 gr.]). and double the dose if necessary.

### Some Points in the Treatment of the Uric-Acid Diathesis.

F. E. Stewart, M. D., Ph. D. (*Therap Gaz.*).

The author's main idea in the above paper is to prove the great efficacy of warm saline baths, as given at certain springs in Germany and in the United States, in the treatment of the uric-acid diathesis. He recommends that in conjunction with the baths there should be administered potassium bicarbonate, in doses of forty grains, to render the urine alkaline; and that a diet be maintained of animal food: milk, 1 to 1½ pints, eggs, fish, fowl, or game, 1 to 4 ounces varied a little from day to day. Of vegetable food, vegetable prepared products, vegetables twice a day; fruit three times a day, to any desired extent, according to appetite. Tea, coffee, cocoa in moderation, and as flavorings rather than as strong decoctions. He also recommends exercise in the open air, preferably under conditions where the mind as well as the body will receive excitation; and indoors by light gymnastic practice, fencing, Swedish movements, and massage. He claims that in many cases the uric-acid diathesis can be successfully treated by the use of the natural saline baths (93°F.) by diet and exercise, without the administration of drugs; and in cases where drugs are necessary, their salutary effects are increased by the baths, etc.

### Absorbing Power of the Bladder.

Physiology has hitherto taught that the bladder is one of the organs which are covered with epithelium and which possess no absorbing power. The author states that clinical observation led him to suppose that the healthy bladder must certainly possess some absorptive power. His experiments consisted in the injection of certain chemical and microbic poisons within the bladder by means of a catheter. Only a slight amount must be injected, so as to avoid the effects of pressure and not cause the animal to urinate at once. Cocoine, strychnine, and medicinal hydrocyanic acid killed the animals within a few minutes. Water appears to be absorbed to some extent by the bladder, but no absolute proof of this can yet be given. The absorption of chemical poisons by the bladder may throw some light upon urinary pathology and give an explanation of the fact that,

from the evolutionary standpoint, renel retentions allows of longer preservation of life and health than retention within the bladder.

Pneumococci, septic vibrios, and the pyretogenic substance of Charrin, when injected in the bladder, all caused death in the majority of instances, after variable lapses of time. Death occurred in five out of six rabbits after pneumococcus injections, and pleural and peritoneal exudations were found to have taken place while there were no renal lesions.

## MEDICINE.

### Elliot (G.) on Appendicitis from the Point of View of the Physician.

From an etiological, as well as from a pathological point of view, the patient with appendicitis has many chances of his disease terminating fatally. Before pus has formed, before ulceration has perforated the coats of the appendix, and before the appendix has become gangrenous and sloughed, the danger to the patient is a prospective one. During this stage of the malady, the physician must adopt a course of active medical treatment. Morphine should be administered in large doses subcutaneously, and should be repeated at short intervals until the pain is entirely relieved. A mustard plaster should be applied until the skin is reddened, and this should be followed by hot flaxseed poultices. A saline cathartic—sulphate of magnesia, in drachm doses, is the best—should be repeated every hour or two, until copious watery movements from the bowels occur. These measures tend to relieve the congestion of the intestinal mucous membrane, and to modify the inflammatory action. If the case is one of so-called catarrhal appendicitis, in which there is no foreign body and no abnormal concretion giving rise to the inflammatory process, the inflammation may undergo speedy resolution and the patient quickly becomes convalescent. But, on the other hand, resolution may not ensue, and the patient may not get well.

If, however, the trouble is caused by a foreign body, or an intestinal concretion, these measures will do little good, except to keep the patient quiet, while the doctor is thinking what to do next.

Cases of this kind, and cases of catarrhal appendicitis, which have not undergone resolution, may be classed together. They are of great gravity and importance. Unfortunately, during the first stage of the disease it is generally impossible to tell just what the cause of the trouble is.

How long may medical treatment be continued? For not more than twenty-four hours, and not later than forty-eight hours, from the commencement of the disease, unless distinct evidence of positive and continuous improvement is observed. If it is not observed, call upon a surgeon to operate, and call upon one who will operate. In this way alone will you do your duty by your patient.—*Boston Med. and Surg. Jour.*

### Rheumatic Skin Eruptions.

Dr. Travers Smith, of Dublin, quoting from Drs. Barlow and Cheadle, says that skin eruptions may be the only manifestation, present at one time, of rheumatism. The rashes, when widely diffused over the body, closely simulate those of measles, German measles, and scarlatina. The difficulty of differentiating is further enhanced by tonsillitis, which may owe its origin to a rheumatic factor. Attention to the following points generally enables one to form a correct diagnosis: (1.) The mode of distribution of the eruption, which manifests itself first on the extremities and may be entirely limited to them. (2.) The *tout ensemble* of the constitutional symptoms, *e. g.*, there being no distinct and sudden invasion or catarrh as in measles. (3.) The time of year. Most cases occur during the cold months and autumn. (4.) The possible concurrent prevalence of an epidemic of an exanthem should be ascertained. The evanescence of the rash and absence of subsequent pigmentation will exclude the syphilides. He quotes as follows from Dr. Cheadle's articles in Keating's *Cyclopædia:* "Always in the case of children, whether unmistakable arthritis be present, or there be merely a stiff and painful tendon, or an unexplained febrile attack, or chorea, or tonsillitis, or erythema, it is most essential to bear in mind the possibility of having to deal with rheumatism, and to examine the heart carefully day by day."— *The Dublin Journ. of Med. Science.*

### Olive Oil in Lead Colic.

M. de Prada records three observations, in which Weill and Combemale employed olive oil in doses of two hundred grammes as a deobstruent and sedative. These therapeutical effects have not been obtained by M. de Prada. The oil in this large dose is with difficulty assimilated by the patients, there being great gastric intolerance. He considers calomel to be superior to the oil; and that it is better to resort to salines, such as the salts of magnesium and sodium, or to calomel combined with sedatives, such as opium and phenazone.—*Lyon Medical.*

### Treatment of Infantile Eczema.

Harrison calls attention to the importance of regulation of the diet, and administration of alterations to the mother in the case of nursing infants. He has found small doses of arsenic (especially minute when the eczema is of highly inflammatory type) to have the best effect. In the way of local applications he prefers unguents to lotions and thinks there is nothing in the argument of non-cleanliness, for oils are really more detersive than water.—*Amer Jour of Obst.*

### Antipyretic Pills in Phthisis.

℞ Pulveris digitalis .....gr. j.
Quininae hydrochloratis.....gr. iss.
Pulveris opii .....gr. ss.
Misce et fiat pilula.
One to be given every six hours.

### Arsenic and Cancer.

Among the ingenious and plausible suggestions emanating from Mr. John Hutchinson, is the possibility of the evolution of epithelioma, being facilitated by a long course of arsenic. In his well-known paper on the subject he alleged a number of instances in which there was certainly presumptive evidence of arsenic having thus favored the evolution of the cancerous outbreak. At a recent meeting of the Clinical society, apropos of a case of multiple epithelioma following a course of arsenic, he called attention to certain peculiar changes in the skin of the palms and soles, which in his opinion indicate that it is time to desist from the administration of the drug, viz., a furfuraceous thickening of the skin in those situations. We call attention to this statement in order that our readers may avail themselves of any and every opportunity of ascertaining how far the suggestion is confirmed by clinical observation.—*Med. Press Notes.*

### Notes on the Physiological Action of Ozone Preparations.

Dr. W. G. Thompson draws the following conclusions respecting the effect of ozonizing agents when given by the stomach or injected directly into the intestines or the blood. The experiments were made on dogs.

1. When injected in the circulation in full strength, i. e., fifteen volumes per cent., they have a very destructive action upon the blood, ultimately having the effect of reducing rather than of oxydizing agents for the tissues.

2. Acting through the stomach or intestines, they may similarly affect the blood, and in addition they destroy the gastric and intestinal mucous membrane.

3. Given in medical doses by the stomach, their only benefit, if any, consists purely in their local action in the alimentary canal, in possibly preventing abnormal fermentations.

4. If so used, care should be exercised owing to the great variability in strength of different preparations.

5. Ozone is of no real value to the tissues, whether inhaled or drunk in fluid preparations, and it may be exceedingly harmful.—*Med. Rec.*

### A New Treatment for Tuberculosis of the Joint and Skin.

The old dictum that "all cyanosis was incompatible with tuberculosis," although originally applied to the lungs led to the suggestion that it might be equally useful in joint and skin affections of the same character. The technique of the method is simple. It consists in placing a broad elastic band around the affected limb a few inches above the diseased part, firm enough to produce venous congestion. The point of application should be changed from day to day to prevent abrasion. The distal portion of the limb is supported by a common roller up to the affected part so that the congested area is limited to the immediate neighborhood of the disease. Dr. Bier of Kiel who originated the treament reports upward of twenty cases in which the improvement attained was very rapid and striking. Miller reports in *Edinburg Medical and Surgical Journal* cautiously this treatment. His plan differs from Biers, in that the bandage is only applied for ten or twelve hours on alternate days. He recommends its use in:

1. Tubercular skin affections of the extremities.

2. Early tubercular disease of joints, (combined with immobilization or blisters,) especially those in which time is of no great importance.

3. Instances of multiple tubercular disease in which more radical treatment is inappropriate.—*Med. Rec.*

### Dangers of Piercing the Ears.

Thorner calls attention to the pathological conditions following the piercing of the lobules of the ears, a custom he considers barbaric, not only because of its origin, and the crude methods by which it is practiced, but for its occasional consequences. Death has resulted from trismus, erysipelas and gangrene, while many observers have reported fibroid growths at the seat of injury, which tend to recur and may become malignant. Thorner reports from his own experience, cases of erysipelas, eczema of the auricle and tumors including fibroma and keloid. These cases lead him to believe that such consequences are more frequent than are usually thought, and he hopes that it will come to be considered an evidence of brutality to have a tender and unprotected child subjected to such an unnecessary and mutilating procedure.—*Jour. Med. Asso.*

### The Etiology of Eczema.

In a paper on this subject read before the Pan American Medical Congress at Washington, Sept. 1893, Dr. A. Ravogli draws the following conclusions:

1. Eczema is a local affection of the epidermis of a chronic inflammatory character, contagious under favorable circumstances.

2. It is caused by pyogenic micro-organisms (staphylococcus pyogenes albus) developed upon a previous inflammation of the skin.

### Treatment of Chorea.

Dr. Abercrombie makes the following suggestions in a clinical lecture concerning the treatment of chorea in children. Unless the attack is very mild, absolute rest of mind and body is essential. Lessons must be given up, and the child kept at home lying down. Most severe attacks demand complete rest in a bed with padded sides. In other severe cases the child should be slung as in a hammock. Only in the lightest attacks should the patient feed himself. When mastication is difficult, minced meat, strong beef-tea, milk, and cocoa should form the chief articles of diet. Sleep is of great importance. If

necessary, chloral hydrate, morphine, or bromides may be administered. Iron and arsenic are the best drugs, though drug treatment is of less importance than general management. Rheumatic manifestations or heart complications should be treated on general principles. In chronic cases douches to the spine, shampooing, massage, and gymnastics are of value.—*The Medical Record.*

### A Bromoform Mixture for Whooping-Cough.

℞ Bromoformi.....mxvi.
Spiritus rectificati.....℥ij.
Glycerini.....℥xij.
Tincturae cardamomi compositae....℥ij.
Mix in the order given.
A teaspoonful to be taken every six hours.

### Signs of Commencing Pericardial Effusion.

In opposition to the almost universally accepted teaching that commencing pericarditis is first manifested by an increase (broadening) of the cardiac dullness at the base of the heart, Ebstein finds that the first alteration occurs in the lower regions of the area of dullness. At first there is a stretching of the pericardium towards the left side, but this is seldom discoverable, partly on account of the occurrence simultaneously of left pleurisy, partly on account of the overlying of the cardiac apex by the lung, partly on account of the loud tympanitic note in the semilunar space. After a short time the pericardial sac will be distended towards the right side also; and this enlargement may be recognized clinically in nearly every case by the appearance of an absolute, or almost absolute, dullness in the fifth right intercostal space in the region named by Ebstein the cardio-hepatic angle (*Herzleberwinkel*). The symptom is all the more demonstrable if it occurs under the observation of the physician, because the possibility of mistaking it for the other processes which bring about complete dullness in this region is entirely excluded. Further, this absolute dullness in the cardio-hepatic angle is of importance for the differential diagnosis between pure hypertrophy of the heart and accumulation of the fluid in the pericardium, because, according to Ebstein, so far as has been hitherto ascertained, absolute heart dullness between the fifth and sixth ribs, even in extreme hypertrophy of the right heart, does not extend beyond the right sternal margin. The cardio-hepatic angle marks also the spot at which, during the retrogression of pericardial effusions, the dullness remains longest observable. A series of clinical histories serves as a proof of the above propositions. —*Virchow's Archiv. Archiv f. Klin. Med.*

### For Laryngeal Phthisis with Dysphagia.

℞ Cocainae hydrochloratis.....gr. x.
Acidi borici.....gr. iv.
Glycerini.....mxv.
Aquae destillatae ad.....℥j.
Misce et fiat applicatio
To be applied to the throat when necessary.

## SURGERY.

### Di-iodoform in Simple Chancre.

Messrs. Hallopeau and Brodier have communicated to the Societe de Therapeutique of Paris their experience in twelve cases of simple chancre treated with dio-iodoform. They arrived at the following conclusions. (1) Di-iodoform may be used in these cases in the same way as iodoform: it generally cures in eighteen to twenty days. (2) It is well borne, and produces neither pain nor local irritation. (3) It has the advantage over iodoform that it gives out no odour, provided it is kept away from the light in well-stoppered bottles. (4) It may, like iodoform, fail to cure in cases of phagedænic chancre. (5) It should be applied several times daily: the ulcer should be kept covered with absorbent cotton-wool impregnated with the drug. (6) It gave good results in a case of lymphangitic abscess of the penis, and generally it is applicable in the treatment of the suppurations and ulcers which are benefited by iodoform dressings.—*Le Progres Medical.*

### An Application for Recent Ringworm.

℞ Thymol.....ʒss.
Chloroformi.....℥ij.
Olei olivae ad.....℥j.
Misce et fiat applicatio.
To be applied night and morning.

## ARMY AND NAVY.

U. S. ARMY FROM MARCH 11, 1894, TO MARCH 17, 1894.

Leave of absence for six months to take effect on or about May 1, 1884, with permission to go beyond the sea is granted Captain Walter W. R. Fisher, assistant surgeon United States Army.

By direction of the president the retirement from active service, March 13, 1894, by operation of law, of Major John H. Bartholf, Surgeon, United States Army, under the provisions of the act of Congress, approved June 30, 1892, is announced.

First Lieutenant Paul F. Straub, assistant Surgeon, United States Army is relieved from duty at Fort Riley, Kansas, and ordered to report in person to the Commanding Officer, San Carlos, Arizona, for duty at that post, relieving First Lieutenant Hurlan E. McVay, Asistant Surgeon United States Army.

Lieutenant McVay, on being relieved by Lieutenant Straub, will report in person to the Commanding officer, Whipple Barracks, A. T., for duty at that post.

A board of officers to consist of Lieutenant Colonel R. Greenleaf, Deputy Surgeon General U. S. Army; Colonel Albert Hartsuff, Deputy Surgeon General, U. S. Army; Major Benjamin F. Pope, Surgeon, is appointed to meet at the call of the president thereof, at San. Francisco, Cal., for the examination of Captain William R. Hall, Assistant Surgeon, with a view of determining his fitness for promotion, as contemplated by the act of Congress, approved October 1, 1890 and July 27, 1892.

Captain Hall will report in person to the president of the board for examination at such time as he may designate.

## ORIGINAL ARTICLES.

### EPILEPSY.*

J. A. LARRABEE, M. D., Louisville, Ky.†

Notwithstanding the fact that epilepsy, as a disease, has been described by the oldest medical writers, and that it is in all probability coeval with the oldest history of man, we are as unable to-day to demonstrate its pathology and indicate its cure, as when 2,380 years ago, it was graphically described by the great "father of medicine." The most comprehensive answer to the question, What is epilepsy? is that it is an explosion of nerve-electrical-force, or, in a word, vaso-motor spasm.

With the exception of those instances where traumatism has established an irritating cause, the brain of the epileptic, dissected after death, shows no lesion which could be made to account for the seizures. While there is a marked leaning of medical authorities to hereditacy as a pre-disposing cause, there is very great reason to doubt it and statistics by no means confirm such a theory.

In regard to chronic alcoholism on the part of either parent, statistics are more conclusive and leave very little room to doubt that drunkenness stands in the relation of cause to effect in the production of epileptic children.

Syphilis—that protean hydra of the human race—has also made claims which are not proven. It cannot be doubted that acquired syphilis is productive of serious organic lesions of the nervous system, but epilepsy is not one of these.

That parents of highly nervous organization, hysterical mothers, and neurotics in general, are likely to transmit to their offspring a diathesis favorable to the development of epilepsy, is entirely agreeable to what we know of diabetes and other neuroses.

Statistics gathered from asylums and hospitals show that one-third of all cases of epilepsy in children have begun before the tenth year of life, and that three-fourths of all before the twentieth year.

Hippocrates, nearly three thousand years ago, wrote these words concerning epilepsy, "The cure may be attempted in young persons, but not in old." This paper is based upon the analysis of twenty cases of well established epilepsy, covering a period of seventeen years, and ranging in age from five to twenty-five. All have been cured, or in other words have been entirely free from *grand* or *petit mal*, since treatment, but the recent cases cover now only two and one year of observation. Of course these still remain doubtful. One case, a girl of ten years who had as many as five or six *grand mal* seizures a month, had a severe spell last September, after a whole year of perfect immunity. She is not included in the above number. It is interesting to note that this attack was undoubtedly brought about by a hearty meal of sausage and pork. The mother remembered, better than I, that I had said in my lectures that the child could be allowed to eat meat at the end of the year if she had no spells. On the anniversary of that day she gave the above *menu* for supper. She has again been put on treatment and has had no return up to now.

*Read before Louisville Med.-Chirurg. Soc., Feb. 2nd. 1894

†Prof. Diseases of Children Med. Dept. Central Univ. of Kentucky.

The first case, seventeen years ago, was an adult who was obliged to give up a lucrative position by reason of the frequency of his attacks. He had been treated for years unsuccessfully by bromides and presented the bromidean acne when he came to me. He remained two years under treatment and is now in California and at last accounts well. He was treated with sulphate of copper and had the copper line well marked upon the gums. Six other adults have been discharged and remain well. One treated by gold has had no spells for six months. The remainder were children at and below the age of puberty. One patient still under treatment with chloride of gold and sodium, although markedly benefited, has been obliged to suspend the treatment on account of bowel and stomach derangement. From my limited experience I have found the salts of zinc and gold to be more irritating than the ammon. sulph. of copper, which I prefer.

I believe, that nitrate of silver in small doses continued long enough to produce argyria, will result in the cure of ninety per cent. of epileptics. But the disfiguration is of such a character that it would be unwarrantable practice without a written contract in which the patient agrees to look all through his life like a highly polished stove-pipe. Believing as I do that the metals tin, copper, zinc, and gold all act in the same manner, namely, storage in connection with the nerve cells in the discharging areas of the brain, I have used them with the above results.

Two of my epileptic patients, not included in the above list, have died in a fit. Both could have been saved had any one been present. One, a most estimable lady, was found face down upon the bed; the other fell into a tanner's vat where he was employed. No epileptic should be allowed to sleep on a feather pillow.

In speaking of my treatment of these cases I claim nothing new or original. The therapeutics of epilepsy has included at different periods in the history of medicine nearly every drug and chemical in the materia medica, nor is it strange that a disease, whose pathology is shrouded in mystery, should in ancient times have been the subject of all that is mythical, mysterious, and superstitious in medicine. Not only has the earth and sea been scoured for remedies, and vile and disgusting concoctions made from the animal and vegetable kingdoms but the planetary system has been invoked and the subtle salts of the alchemists have had their day and, what is stranger still, their cures. The charm and the amulet, the mistletoe gathered under the exacting rules of the Druids, have all cured under the dominant idea.

*Bromides:*—The introduction of bromic acid united with various bases marks an important era in infantile therapeutics. This is the "sweet oblivious antidote" dreamed of by the immortal "Bard of Avon" with which we may "erase the writ tablets of the brain." While the bromides are inadequate to the cure of confirmed epilepsy, they are of all agents the best, to obtund the brain to peripheral impressions. Their sphere of action is in the prevention rather than in the cure, and some one of the salts of bromine should be continued for two weeks after a fit of eclampsia in the infant or child. A longer continuation is apt to produce unpleasant symptoms of bromism. Ammonia is the best base for any of the acids, therefore preferable to potash. In adults these agents, carried to their toxical effect, secure often long immunities to a seizure, but only so long as a condition bordering upon imbecility lasts. With a cessation of the drug and a return of the nerve centres to their pristine vigor, the attacks return in full force. It is quite different with the child and some permanent cures may be expected in the growing brain from the administration of bromides.

*Nocturnal Epilepsy, Night Terrors or Nightmare*: The fact that epilepsy may exist for a long time unobserved is important. When a strong healthy man or woman is heard to utter a cry and seen to fall to the ground in a convulsion, attention is attracted to them. When a child stops for a moment at its play and fixes its eyes upon some object, remaining immovable for a moment of time, and then without any other manifestation resumes its play as though nothing had occurred, no attention is paid to it. Such attacks, however, constitute the "*petit mal*" of epilepsy. "Not infrequently children awaken in the morning complaining of violent headache and the soiled and disarranged bedding afford the only evidences of a struggle concerning which the child has no recollection." Such instances are by no means uncommon and their true nature is only revealed by

some fellow occupant who is put to watch them.

The relation of night terrors of children to epilepsy is also a matter of very great importance. This distressing condition often "poohed" at and less frequently but too often made the subject of chastisement, has a marked effect upon the growing brain and forms the background in the history of many an adult epileptic. Children who by inheritance are possessed of a neurotic diathesis are more prone to such attacks.

When such authorities as Hennock, of Berlin, and Goodheart, of London, make the statement that they do not consider food to be a factor of any prominence in the etiology of night terrors, it may seem presumptuous for me to compare my limited opportunities of experience with their extensive observation. Nevertheless an honest difference of opinion, however humble the source, is offered in the spirit of truthful investigation. From that experience I am forced to conclude that not only certain foods, but also the time at which they are taken, has largely to do with the production of night terrors and consequently with the development of epilepsy in childhood. I have met with very few where the night terrors were not traceable to injesta in the intestinal tract and with none in which a regulation of diet, especially the last meal, did not inaugurate an improvement and an amelioration of the night attacks.

Nitrogen is an essential element in gun powder and other explosives with the destructive force of which we are only too familiar. It is scarcely less dangerous and destructive when circulating to an excess in the blood of animals whose nerve force it has the power of suddenly discharging. Epilepsy may be produced at will in the young of even carnivorous animals by feeding raw meat during the period—(formative)—of lactation. Kittens so fed, will develop fits in a few days which prove fatal if continued, but which cease with the withdrawal of the meat. Horses over-fed with stimulating, nitrogenous foods, have epilepsy and fall trembling in the harness. A piece of raw beef steak with tea or coffee at supper will be as equally certain to cause an uproar in the nursery during the night.

It is a suggestive fact that the brightest minds that have adorned our nation, and the greatest statesmen who have figured in history, were put to bed as children upon bread and milk or oaten porridge. Whether or not the "meat and morals" of the great Russian reformer Tolstoi, shall receive scientific endorsement is yet to been seen, but quiet sleep and brain rest in children are both incompatible with meat, tea and coffee. Nine-tenths of all the various convulsive manifestations in infancy and childhood have their origin in intestinal irritation or from a loaded bowel, packed cæcum or intestinal worms.

I can remember when I used to prescribe bromide, chloral, sulphonal, etc., for the muscular, gastrocnemius cramps of elderly people, with some temporary benefit. Latterly, however, I have found much in common between childhood and age. I find that an acid condition of the jejunum and ileum from faulty assimulation of faulty food is the cause of the acidity, and I have also found that a simple alkali, as soda bicarb., taken on retiring secures exemption from the trouble.

The intellectual status of confirmed epileptics is often a matter of astonishment when we take into consideration the apparent gravity of the seizures. When an explosion occurs in one of the discharging areas of the brain, the senses are under shock and a condition like concussion occurs in the centers of conscious thought. Nearly always, before the suspension of consciousness, the victim ejaculates a word or sentence, which word or sentence remains peculiar to the individual, and then immediately the memory is obliterated. Often the aura is through one of the special senses, as vision, smell or peripheral irritation. The same object is seen, the same odor is smelled and the same peripheral zone is felt before each seizure. My experience among children leads me to indicate more frequently an ocular spectacle which is remembered as a ray of light approaching and blinding the victim. As regards the vigor of the intellect of epileptics, it must be admitted that in the growing age it is impaired by the attacks and often results in imbecility, while in age memory becomes almost entirely obliterated and the various manifestations of softening occur.

The fact that some of the world's greatest masters have been life-long epileptics must not be forgotten. The greatest epochs in history have been inaugurated by epileptics, while poet have sung and martyrs have suffered unde

its strange hallucinations. Upwards of a hundred millions of the world's population to-day bow the knee as devotees to the erratic religious devotions of an epileptic, whose prophetic visions and vagaries were but a part of his epilepsy. The old Roman wall of England, the broken arches upon the Rhine, the lofty peaks of Cis-Alpine Gaul bear silent witness to the indomitable will, fortitude and genius of an epileptic, who lived before the Christian Era; while in the still remembered years of modern history we recall the burning of Moscow, the carnage of Austerlitz and Jena, and the culminating battle of Waterloo as the work of an epileptic whose gigantic intellect was extinguished amid the tempest of that awful night at St. Helena.

Persons who develop epilepsy after the age of puberty appear to retain their mental vigor in the interval of the attacks, and are often capable of attending to all the duties of life. They are moreover possessed of strong will power and determination. If a religious trend has been given to their character, they become very devout, often fanatical, and make sacrifices which would be quite impossible for ordinary individuals.

Confirmed epileptics often enjoy immunity to attacks by a pre-occupancy of the mind or by engagements in hazardous undertakings, e. g. A famous church spire painter who worked in Louisville was an epileptic, and could be seen any day suspended upon his airy platform 150 feet above the ground. He never had a spell while aloft pursuing his work, but once back upon *terra firma* he would be seized with a fit. So marked is this feature that treatment by a new physician, especially if he be a celebrity, often secures a long immunity to the seizures. The knowledge of this fact should caution us against attributing the relief to our therapeutic measures.

Epileptics seldom die in a paroxysm but oftener live long and useful lives. A gentleman well known in this city and throughout the state, whose Christian example and good works will be handed down to future generations, has been an epileptic from boyhood. He was refused life insurance over 40 years ago and has outlived every one of the agents and physicians of the company. He has been twice paralyzed, first right and then left hemiplegia, and is to-day a sound reasoner and thinker.

I desire to call especial attention to the importance of the treatment of infantile eclampsia. The commonly accepted fact that convulsions—epileptiform—are of frequent occurrence in inverse proportion to age, may possibly be the cause of carelessness in general practice, the consequences and the importance of a complete restoration of the nerve centres is forgotten. The foundation for future epilepsy is thus laid. This is about the way it runs: The family physician is called to a child in a fit, he arrives—is informed that it is all over—the child has had a spasm but is now sleeping quietly; if he wishes he can come in and see it. Now, instead of explaining to the friends the importance of after treatment, care, diet and possible medication, he is too apt to say, "Oh, never mind, I guess it will be all right, and if he has any more trouble let me know."

The increasing tendency to convulsions in infancy may be attribued to two principal causes, namely, first, the more perfect development of the animal brain—cerebellum; second, the immature development of the intellectual brain—cerebrum.

All the acts and functions of the new born babe are reflex, rythmical only becoming manifest with the deposit of gray matter, e. g., Cheyne-Stokes respiration denotes serious disease in a child and adult, but it is the normal respiration of an infant. The pulse has no regularity and noise and slight concussion are responded to, as in a frog poisoned by strychnine. Gradually, however, the will power "that column of true majesty in man" develops and asserts its power over the spinal system. Just in proportion to this development or non-development an infant remains liable to convulsions. Every practicing physician knows of families possessed of such a diathesis and learns that a hasty summons on account of some trifling ailment means a spasm. A child who has had a convulsion from any of these causes is more liable to have another from a lesser cause and so on until finally a "status epileptica" is established, after which the fits occur without any apparent cause. We know comparatively little of the process by which such photographic impressions are made upon the growing brain of the infant, but we do know that the stains are well nigh indelible.

## DENTITION WITH DISEASES OF THE TEETH AS A CAUSE OF EAR DISEASE.

LAURENCE TURNBULL,* M. D.

Every physician of experience has found that eruption of the teeth is a cause of earache, followed by pain and a discharge of pus and a laceration of the drum membrane. Especially so when (as frequently happens) the teeth are so impacted that they cannot erupt, if not relieved by lancing the gums. Again the so-called wisdom teeth, from their reflex irritation and pressure, are a cause of deafness and should be removed. Caries of the teeth, caused by acids and fungi (lepothrix fuocatis), is usually attended by both toothache and earache from extension into the ear by the Eustachian tube. The gums, buccal cavity and alveolar processes are rich in blood vessels and nerve filaments from the fifth pair to each, and the whole of the nerves which are spread over the jaw bones, both upper and lower.

If children and adults are of feeble frame and the vitality is lowered by constitutional diseases like syphilis, scrofula or consumption, the teeth are generally of a chalky, white color, brittle or soft, and decay with great rapidity by the action of the *lepothrix* living on carious stumps, which decay impairs digestion and nutrition. When a "cold is taken," these stumps being dead, there is almost always an attendent coryza. This affects the ears, causing a "running ear" better known by the term otorrhœa, but more correctly as an acute otitis media catarrhalis or purulentia. Trophic changes also occur in the Eustachian tube or middle ear with alveolar abscess or with disease of the antrum of Highmore. The nasal mucous membrane is also a fruitful cause of ear trouble.

The accretion on the teeth known by the popular name tartar—properly named calculus—is a deposit of lime salts from the saliva. Among the secretions of the salivary glands, that of the parotid alone may be feebly acid; that of the submaxillary and sublingual glands is, on the contrary, constantly alkaline. This fact has been proved by the aid of sounds introduced into the efferent canals of these glands. The secretion of the parotid is sometimes acid when first collected; but this reaction passes promptly to the neutral state, or to one slightly alkaline, when the liquid loses the clearness which it possessed at first. This acid reaction arises, according to M. Oehl,† from the carbonic acid absorbed in the liquid, which holds in solution the carbonate of lime with which the liquid secreted by the parotid is abundantly provided. When carbonic acid disappears, the acid reaction ceases to take place and the carbonate of lime which it holds in solution is precipitated.

"This circumstance explains the formation of the tartar upon the teeth. The fact that this sometimes contains a large quanity of phosphate of lime at the same time with the carbonate, is not in contradiction with this explanation, inasmuch as the carbonic acid may hold phosphate as well as carbonate of lime in solution. The precipitates of the calcareous salts inclose numerous elements of *leptothrix* and of other products which are met with in the mucosities of the mouth, such as epithelial cells, leucocytes, etc."‡

The tartar, it is stated, protects the tooth substance, but by pressing away the gum and causing absorption of the process, it causes irritation and loosening of the teeth, and gives rise to changes in color and healthy character of the gums, and the whole buccal mucous membrane; this red condition extending into the throat and ear is often an indication of disease of the bronchial tubes and lungs.

We leave the matter of getting rid of dental diseases, caries, calculi, etc., to the competent dentists of the present day, having every confidence in their judg-

ment in all matters connected with their specialty.

We add from long experience as a physician some most judicious advice on the care of the teeth. Our first object should be the use of prophylactics, and by avoiding strong acids, to get rid of those which are formed in the mouth by fermentation or sepsis, and prevent the growth of the fungi, which are of the same nature as those which are found in the ear. Rub the teeth and gums night and morning, using a moderately hard brush and water with pure castile soap; this produces a slightly alkaline solution, which should be applied well to the teeth. In some cases the soap is not quite alkaline enough, then the addition of a portion of the bicarbonate of soda on the brush; or, if a stronger agent is required, a solution of permanganate of potassium in water (grain 1 to the ounce) will be found a most valuable antiseptic. Care must be taken that no metallic substance or foreign body should come in contact with this salt, as it gives up its oxygen and becomes decomposed. A glass dropper and glass stopper is always necessary in using so delicate an article. This is to be followed by a fine tooth powder, not gritty, made of chalk and orris root, with a few drops of perfume.

In hospital and surgical practice a solution of the permanganate (24 grains to the ounce) is usually kept on hand as an antiseptic, deodorant and detergent. Of this solution half a drachm, or thirty drops, may be added to a pint of boiling water, this can be used in the nose, mouth, throat and ear, when there is a discharge of pus from the meatus.

In passing we would simply state our personal experience in regard to dental plates. These should be of gold, platinum and dark vulcanite. Certain forms of vulcanite colored by mercury (vermillion) we have found to produce disease of the gums and buccal cavity extending to the ear, notwithstanding, it is stated that "pure sulphuret of mercury fused in vulcanite is reckoned by Orfila as medicinally inert."§ Every plate of this kind should be removed at night and brushed in soap and water.

In regard to fillings, we prefer gold but there are cases in which gold cannot be used; then a soft material should be used free from acids and mercury. In modern dentistry cements of zinc oxide and glacial phosphoric acid should be used and are universally approved. So are amalgam fillings, but all mercury must be carefully avoided. If the tooth or teeth are very defective from caries — extending into the roots—their removal is usually an absolute necessity, and fitting by a plate or plates should follow. Dentists do not consider teeth hopelessly gone so long as the roots remain firm and capable of being cleansed and rendered aseptic, so that pivot teeth can be fitted to them. It is otherwise, of course, when there is chronic abscess, or decay has extended beyond the pulp cavity into the root body.

The following is a list of some of the diseases of the ear due in part or wholly to reflex irritation of the teeth: Acute and chronic catarrhal inflammation of the middle ear; acute, subacute and chronic purulent inflammation of the middle ear; otitis externa, alveolar abscess, and ozœna. Sometimes we have found the metal filling forced down into the jaw by too great a pressure of the mallets, which are now used, and in one case such was the cause of profound deafness; hearing was improved after the removal of the pressure. Such a case as this, however, is fairly to be charged to malpractice. No dentist should dream of packing gold or other metal in the apices of the roots; the apices may be closed with other kinds of stopping, is (none of which ought to be, nor usually is, so forced as to extrude), and *then* the body of the root is filled with gold or other material.

# SOME ANATOMICAL AND SURGICAL RELATIONS OF THE PARTS INVOLVED IN THE OPERATION OF INTRA-CRANIAL NEURECTOMY OF THE FIFTH PAIR OF NERVES AND REMOVAL OF THE GASSERIAN GANGLION.*

WILLIAM J. TAYLOR, M. D.,†

Intra-cranial neurectomy of the fifth nerve and the removal or destruction of the Gasserian ganglion must now be given its place as one of the most brilliant and difficult operations in surgery.

Rose and Hartley have given us very definite directions as to the mode of opening the skull and general surgical technique, but I have failed to find an exact statement by anyone of the relative positions of the foramina, the ganglion, and arteries. It is with the hope of adding to our knowledge of these anatomical and surgical relations that, at the suggestion of Dr. W. W. Keen, I have lately made a careful study of the interior of twenty skulls taken in the most part from the collection in the Mutter Museum of the College of Physicians. My aim has been to establish by accurate measurements the distance between the foramina of exit of the second and third branches and to establish definitely their relationship with the foramen spinosum, the carotid canal, and the depression or fossa for the ganglion. As is well known this ganglion, a reddish-gray band of ganglionic matter slightly curved in its long axis so as to present a convexity forward and outward, rests upon a depression in the petrous portion of the temporal bone. From the convex antero-external border, three large bundles of nerve fibres arise.

The *first* or ophthalmic division is the smallest and is purely sensory in function. It arises from the upper portion of the ganglion, enters the cavernous sinus, and passes forward in contact with the outer wall of the cavernous sinus, through the sphenoidal fissure into the orbit.

The *second* or superior maxillary division, also a sensory nerve, passes out through the foramen rotundum and enters the orbit through the spheno-maxillary fissure.

The *third* or inferior maxillary, the largest of the three divisions, consists of two portions: the larger or sensory root arising from the inferior angle of the ganglion, and the smaller or motor root passes beneath the ganglion. This latter accompanies the sensory root and joins it after it emerges from the foramen ovale.

A small branch, the *recurrent*, passes into the cranium through the foramen spinosum along with the middle meningeal artery. This divides into two small branches to be distributed to the dura mater and to the lining membrane of the mastoid cells.

As will be seen by this short account of the three divisions of the fifth nerve, it is impossible to make a definite section of the first division without doing great damage to the cavernous sinus, the third, fourth, and sixth nerves, and the carotid artery.

We must be contented to cut the attachments and remove or destroy the ganglion, and with it the second and third division as they pass through the foramen rotundum and foramen ovale.

The middle meningeal artery as it enters the cranium through the foramen spinosum must frequently be wounded or torn through in our endeavors to reach the ganglion. For this reason it is often wiser to ligate and deliberately cut it than to run the risk of tearing it as it passes through the foramen; when by any chance this occurs our only means of controlling the hemorrhage is by packing the foramen or the ligation of the external carotid artery below the origin of the internal maxillary artery.

In this examination for convenience, and because it is a measure with which we are all familiar, I have taken the inch and its subdivisions of sixteenths as the most readily understood and easiest obtained unit of comparison.

*Read before Phila. Co. Med. Soc. February, 14, 1894.

†Professor of Orthopædic Surgery in the Philadelphia Polyclinic; Attending Surgeon to St. Agnes Hospital; Assistant Surgeon to the Orthopædic Hospital and Infirmary for Nervous Diseases.

*First.* I have measured the distance, centre to centre, from the foramen spinosum to the foramen ovale; from the foramen ovale to the foramen rotundum, and from the foramen spinosum to the foramen rotundum.

*Second.* I have measured centre to centre, the distance by which the foramen ovale is in front of the foramen spinosum, taking the sides of an imaginary parallelogram, the foramen spinosum being the external and posterior, and the foramen rotundum the anterior and external points.

Also, the distance by which the foramen ovale is internal to the foramen spinosum, the distance by which the foramen rotundum is anterior to the foramen spinosum, and the distance by which the foramen rotundum is internal to the foramen spinosum.

*Third.* The diameters of the three foramina—spinosum, ovale, and rotundum.

*Fourth.* The distance between the centre of the foramen rotundum and the depression or fossa for the ganglion, and from the center of the foramen ovale to this fossa for the ganglion.

*Fifth.* The width of the bridge of bone between the foramen ovale and the carotid canal.

In going over these skulls carefully I have found such a great inequality in the measurements between the two sides that I have made a definite note of these variations, and give in my table the greatest, the least, and the mean measurements. Possibly a better understanding of the system of measurements may be gained by a glance at Fig. 1, which shows the relative positions of foramina, etc.

I have also had made a series of twelve photographs, and of these have selected four of the most typical. In these the inequality is seen most distinctly.

The distance between the centre of the foramen spinosum and the centre of the foramen ovale varies from 2 to 9, with a mean distance of about $4\frac{11}{16}$ sixteenths of an inch.

The centre of the foramen ovale to the centre of the foramen rotundum varies from 6 to 13, with an average of between $9\frac{5}{16}$ and $10\frac{7}{16}$ sixteenths of an inch.

The centre of the foramen spinosum to the centre of the foramen rotundum varies from 8 to 17, with an average of between $13\frac{5}{16}$ and $14\frac{11}{16}$ sixteenths of an inch.

The centre of the foramen ovale is anterior to the centre of the foramen spinosum from 2 to 6, with an average of from $3\frac{5}{16}$ to $3\frac{7}{16}$ sixteenths of an inch.

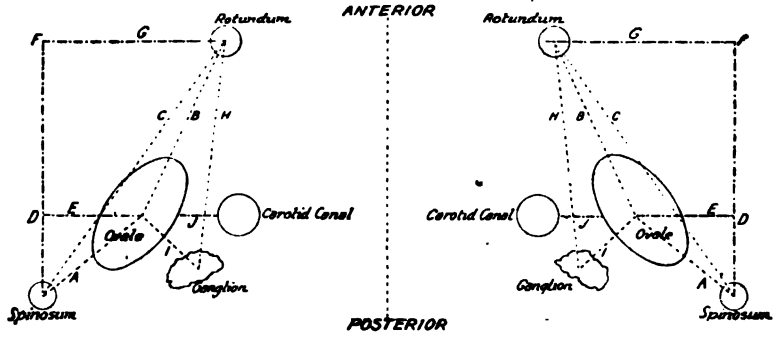
The centre of the foramen ovale is internal to the centre of the foramen spinosum from 2 to 6, with an average of from $3\frac{5}{16}$ to $3\frac{11}{16}$ sixteenths of an inch.

The centre of the foramen rotundum is anterior to the centre of the foramen spinosum from 9 to 14, with an average of from $11\frac{5}{8}$ to 12 sixteenths of an inch.

The centre of the foramen rotundum is internal to the centre of the foramen spinosum from 4 to 11, with an average of from $7\frac{11}{16}$ to $8\frac{1}{16}$ sixteenths of an inch.

The distance from the centre of the foramen rotundum to the centre of the

FIG. 1.



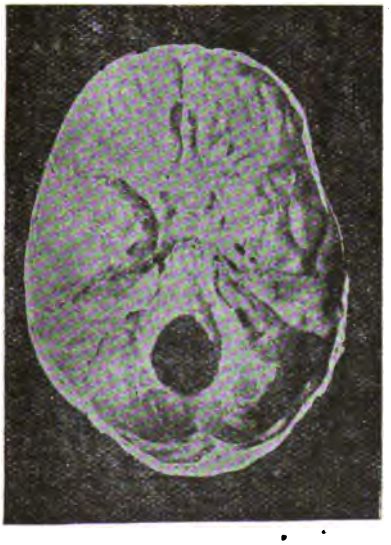
*A*, Spinosum to ovale. *B*, Ovale to rotundum. *C*, Spinosum to rotundum. *D*, Ovale anterior to spinosum. *E*, Ovale internal to spinosum. *F*, Rotundum anterior to spinosum. *G*, Rotundum internal to spinosum. *H*, Rotundum to ganglion. *I*, Ovale to ganglion. *J*, Bridge of bone between foramen ovale and carotid canal.

fossa for the Gasserian ganglion varies from 8 to 16, with an average distance of between 13 and $13\frac{6}{16}$ sixteenths of an inch.

FIG. 2.

The centre of the foramen ovale is distant from the centre of the fossa or groove for the ganglion from 2 to 9, with an average distance of $5\frac{1}{16}$ sixteenths of an inch.

FIG. 4.

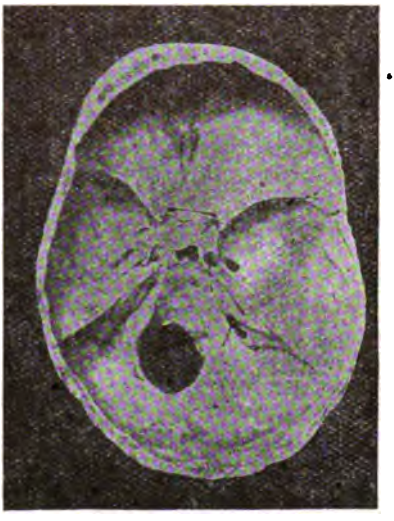


The width of the bridge of bone between the foramen ovale and the carotid canal varies from 1 to 9, with an average width of from $4\frac{1}{16}$ to $5\frac{1}{16}$ sixteenths of an inch.

The diameters of the foramina have been determined to be as follows:

The *spinosum* varies from less than 1 to 3, with an average of from $1\frac{2}{16}$ to

FIG. 3.

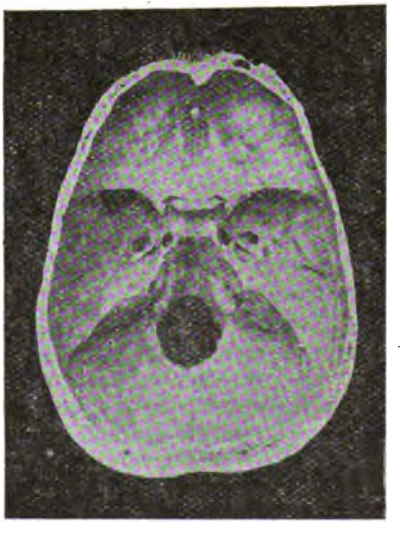


$1\frac{13}{16}$ sixteenths of an inch.

The *ovale* varies from 3 to 6, with an average of $4\frac{13}{16}$ of an inch.

The *rotundum* varies from 1 to 3, with an average of between $2\frac{1}{16}$ and $2\frac{3}{16}$ six-

FIG. 5.



teenths of an inch in diameter.

It will be seen by these measurements, and by a glance at the accompanying photographs and table, that the relation-

ship between these different points is by no means constant, and in operating we must realize the fact. In the majority of instances the foramen spinosum with the middle meningeal artery is far enough away from the foramen ovale and the third branch of the nerve, to enable us successfully to cut the latter without wounding the bloodvessel. This is particularly marked in Fig. 4, on the left side, where the distance is $\frac{2}{16}$ of an inch. On the other hand, the spinosum may be so nearly in a line with the ovale that to reach it without wounding the middle meningeal artery would be impossible. In some of the reported cases of

The rotundum is most constant in its shape and its variations are of little importance to the surgeon.

The spinosum varies much, and in one instance (Fig. 3), as is well shown in the photograph, there are two distinct foramina on the left side.

The character and sex of the skull seem to have little bearing upon the relative position of the foramina, with the exception that a broad, flat skull usually shows a greater distance between them, and it has been impossible to fix upon any rule by which these variations may be anticipated.

---

the operation, where mention is made of alarming hemorrhage, I am convinced this state of affairs existed.

For this reason, whenever the exposure of the third branch of the nerve is at all difficult, the surgeon should at once search for, ligature the artery, and cut it across, before attempting to find the nerve. This ligation of this artery is not very difficult, and will at once give much greater freedom of action.

The size and shape of the foramina vary in different skulls; especially is this so with the ovale, which is at times perfectly round.

IN spite of the suspicion which attaches in many minds to the use of "hyponotic suggestion," its therapeutic practice seems to be rapidly gaining ground in this country. Not long ago the British Medical Association, after hesitating for a year, found itself compelled to "receive" the favorable report of the committee it appointed to investigate the matter, and it is noticeable that the tone of the medical journals has gradually changed from one of open hostility to a more or less favorable tolerance.—*London Public Opinion.*

EVERY man has as much right to kill himself as he has to live a useless life.

# AMERICAN GRIPPE, OR MYXOIDŒDEMA.*

CARL SEILER, M. D., PHILADELPHIA.

I have been asked to present my observations of American grippe and its after-effects. Of course, the subject is one which is so interesting to all of us, and which is, unfortunately, so mixed in the minds of many, that it will be possible for me, in the short time, to give only a *résumé* of the subject. Therefore I hope that the few remarks that I shall make may be of sufficient interest to the members of the Society to call forth their expression of opinion and relation of clinical observations of much more value than my own.

In 1885 I observed the first case of this peculiar disease. I afterward (in 1887) discussed the subject with Dr. Glasgow, of St. Louis, who, strange to say, had made observations similar to my own; and as there was no disease which had been described which, to our knowledge, came anywhere near the one under discussion, he had called it "It," and so had I. The disease was first described by me in a paper published in April, 1889. Dr. Glasgow reported his observation to the American Laryngological Association in May, 1889, and in June of the same year I read my paper before the American Medical Association as its meeting at Newport. You may remember that at that time I referred to the fact that the disease was spreading all over the country, and that I had received letters from Montana, Washington, the Canadas, from the South, and, in short, from all directions, after having made inquiry about the new disease. Geographic situation, elevation, temperature, and atmospheric conditions apparently had nothing to do with its causation; in fact, the disease was everywhere the same in its specific characteristics.

In 1889, in the month of December, the disease broke out in New York City, where it assumed the proportions of a very alarming epidemic, and its existence was recognized as an epidemic general and fatal all over the United States within a very few weeks after its recognition in New York. Unfortunately it was called "la grippe," or the Russian influenza, a disease differing entirely in its clinical character and prominent pathological lesions from the disease erroneously named by the public press. I then published a paper in March, 1890, in which I gave the differential diagnosis between the Russian influenza, or "la grippe," as well as of other diseases mistaken for it, and the American disease. Last March (1893) I published the fourth edition of my book on *Diseases of the Throat*, in which I devoted an entire chapter to the consideration of this disease, under the name of "American grip," or myxoid-œdema, to distinguish it from the "Russian" or European influenza. The distinction is similar to that which we are accustomed to make between measles and German measles, or morbilli and rubella (Rötheln).

The peculiar symptoms of the American grip are: the sudden onset; the rheumatic pains, in all parts of the body, accompanying the sudden onset; an abrupt rise in the temperature, with moist skin; a peculiar tension; no inflammation of mucous membranes. In some cases a deposit of pseudo-membrane occurs upon the tonsils and elsewhere, which, however, is of entirely different character from the pseudo-membrane of croup and of diphtheria. There is a peculiar puffiness of the mucous membranes, which shows itself wherever the deposit is most developed. It occurs in the throat, in the larynx and nose, in the bronchial tubes, and in the mucous membrane of the intestinal tract. In its prostration of the vital powers of the body the disease is something like typhoid fever; but with it there is no fever, no exacerbation of high temperature; there is no thirst, no dryness of the skin, and no brown coating of the tongue. In one case the temperture was 105° F. at the beginning, but it went down to normal in twenty-four hours. The pulse was 76 right along, and had none of the characters of a fever pulse. In those cases in which death occurred the temperature was reduced to normal, or even subnormal, and the giving out of the heart was the original cause of death.

*Read before Phila. Co. Med. Soc. February 28, 1894.

In some cases the submucous infiltration is most evident in the vocal bands, and here the consequent closing up of the larynx causes suffocation. The immediate cause of death is usually a small hemorrhage in the mucous membrane in such cases. Ecchymotic spots are often observed in the throat, bronchial tubes, and also in the stomach and intestines. Indeed, there may be black vomit, like the black vomit of yellow fever, and the stools may also show the presence of effused blood.

I am now speaking of the symptoms of American grip. I need not refer to the symptoms of Russian grippe, since I could not add anything to the admirable review of them given by my friend, Dr. J. C. Wilson, in his article on "Epidemic Influenza," in Pepper's *System of Medicine*, which you are already familiar with.

In the matter of treatment I have found the greatest benefit from a long-discarded drug—which, I must admit, is of no use in any other disease—the benzoate of sodium. In American grip it acts as a specific, precisely as quinine acts in malarial fever. It relieves the pain at once; it brings down the temperature; it relieves the oppression of breathing, and removes the false membrane from the throat. This remedy, with alcohol and rest, constitutes the whole treatment of the disease. In my experience I have found that it is an absolute specific—of course, provided that the diagnosis had been correct. As to other drugs, I would say that all those patent coal-tar remedies are only a cause of death. They act as heart depressors, when the heart is already profoundly depressed by the disease. Antipyrine, antifebrin, and all the other antis are worse than useless. The heart needs to be supported, and they all cause further depression. Quinine is often a cause of insanity and suicide. During the last three years I have made a careful investigation of all published cases, whenever possible, where insanity had been the cause of death in grippe, and I found that quinine in large doses had always been given to the patients. I have observed, in my own cases, that even very small doses of quinine will often cause mental disturbance.

Thus far I have considered only the acute condition. If benzoate of soda is not given, and the patient does not remain in bed, a chronic condition of grippe will be produced. This is a very distressing condition, as I know from personal experience. The symptoms are so different that they cannot be given in detail, and it is difficult to make a diagnosis. There is a flabby, pale, or coated tongue, want of appetite, impaired digestion, irregularity of bowels. With this there is a depression of spirits, want of ambition, and inability to perform any work requiring exertion of mind or body. A little overexertion will throw the patient back, and it will be days and days before he can regain his former position and begin to gain strength.

The pathology of the chronic cases has been shown to be a slow process of fatty degeneration of all the organs of the body except the kidneys. And, if there has not been pre-existing disease of the kidneys, there will be no albumin in the urine.

The chief symptoms of the chronic form are general neurasthenia, associated with chronic distention of the venuoles, and anæmia of the arterioles throughout the body. This was seen by ophthalmoscopic examination in the eyes, when it produced impaired vision or blindness. Blueness of the skin is due to the same venous congestion, evidently of neurotic origin. Besides the mental depression, there are hallucinations of peculiar character and irritability of temper. Light has a depressing effect, while darkness causes exaltation. Toward evening the patient usually feels much better than in the early part of the day. I have observed that a patient may go to sleep at ten o'clock and wake up at eleven in a state of mental exaltation. He feels like getting out of bed and walking about his room, or relieve his mind by writing poetry; this is the only thing that will enable him to go to sleep again. I have some very curious specimens of this "grip poetry" in my possession. The irritability of temper I have referred to is beyond the control of the patient, although he is fully aware of it; this is part of a hysterical condition, and under slight exertion or emotion, a condition of hysterical aphonia may be developed even in men. Then, again, the patient is very much disturbed by all kinds of rhythmical noises, especially at the seashore, where the "one, two, three" of the breakers nearly drives him out of his senses. Even if he cannot hear them, he is conscious of annoyance from the rhythmical repetition

of the waves, and this will make him extremely nervous, so that he cannot sleep. The rapid succession of the trolley-car bells are also very annoying, and I have had patients who were driven out of the city by these noises.

The treatment of the chronic grip is by alterative tonics. Buchu may be given as a mild diuretic. If there is sleeplessness, bromides are useful. All the coal-tar preparations are bad. Of the narcotics, the best is hyoscine in small doses; as a tonic, strychnine in considerable doses, beginning with gr. $\frac{1}{32}$ up to gr. $\frac{1}{16}$ three or four times a day. A change of climate is advisable, and the best I have found is a moderately high place, where there is plenty of oxygen and an absence of noise. Mineral waters are valuable, and I found at Bedford great advantage from the use of the water, but there is a spring at Swift-water, near Pocono, which I consider even better.

The wine of coca is especially useful when the patient begins to exercise as a "pick-me-up." I came across, the other day, a sample of wine of coca made by the Columbia Chemical Company of Washington City, which I found very much better than any I had previously met with, as it gave much satisfaction in the cases for which I had ordered it. Where the patient must keep at his work the coca is a valuable remedy, as in the case of a preacher who has not suffiient strength to go through with his sermon without some such aid.

## REMOVAL OF THE GASSERIAN GANGLION.

It seems still to be a disputed point whether or not the Gasserian ganglion can be removed. So far as we are able to judge, there is nothing that can be regarded as absolute proof that more than a small part of it has been removed in cases of severe neuralgia in which the nerve has been attacked so near its origin; but whether it is removed or not is a matter more theoretical than of practical interest so long as the cases which are operated upon are relieved of the pain which render their lives a burden.

The operation designed and most skillfully carried out by Mr. William Rose consists in exposing the outer surface of the foramen ovale and applying the trephine to this part of the wing of the sphenoid and so exposing and removing the anterior and outer part of the Gasserian ganglion. His operations have been attended with a very gratifying amount of success. It is a severe procedure, and not unattended with difficulty.

Other ways of reaching the ganglion have been suggested, notably Mr. Victor Horsley's. A very useful modification of the operation has been introduced by an American surgeon, Mr. Hartley, which he described, together with a case on which he operated. Briefly it may be stated as consisting in reflecting the tissues, including the bone, over the temple, the base of the initial curved incision being over the zygoma, and the flap being reflected downwards.

Broad retractors are used to raise the dura mater with the brain, the foramen rotundum and foramen ovale are exposed, the nerves are traced back to the ganglion, and it and the nerves between it and the foramina are excised.

Dr. Tiffany, of Baltimore, in a recent number of the *Annals of Surgery* calls attention to the method and gives particulars of four cases operated upon by it. His cases all did well, apparently; of the four, three have since been observed. In one of the cases, seen 13 months after operation, there was no return of pain, nor was there any pain in the other two, in which, however, only a few months had elapsed since operation. The fourth patient was not seen after he had left the hospital. In the three cases examined it is interesting to find that the persistently anæsthetic freas were very similar. There was a large area around the mouth and over the aace and the lower part of the nose, and another smaller area in the temporal region. Taste was normal in all three cases; a little discomfort was caused by the food lodging between the gum and cheek, a result apparently of the division of the motor branch of the fifth. It may be mentioned that in all these cases the superior branch of the fifth was left alone, and no trophic troubles, ocular or of any other kind, ensued. It is yet too early to be certain that the pain will not return. It is to be hoped that it will not, but, as is well known, even a year of freedom is no guarantee in such cases of an absolute cure.—*The Lancet*, 1894.

147-149-151 North Tenth Street, Philadelphia

TERMS:—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MARCH 31, 1894.

## EDITORIAL.

### MEDICAL EXPERTS AND THE VALUE OF THEIR TESTIMONY.

The medical expert question should be one of great interest to the profession. No physician is exempt from being called into our courts to testify in cases in which important personal and community interests, often human life, are involved. It is presumed that the physician's greater opportunities for observation and closer study respecting the subjects pertaining to his profession, give superior skill in relation to those subjects and entitle his opinions to be received as those of an expert. Courts have laid it down as a definite rule, that an expert must have made the subject upon which he gives his opinion a matter of particular study, practice, or observation, and he must have particular and special knowledge on the subject. The facts to which he testifies must be scientific facts, as near as it is possible for human knowledge to reach, and not mere theoretical fancies.

Expert opinion is only taken upon questions of science, skill or trade, or others of like kind, or when the subject matter of inquiry is such that inexperienced persons are unlikely to prove capable of forming correct judgment upon it without such assistance, or when it so far partakes of the nature of a science as to require a course of previous study.

The very notion of a science springs from the recognition of the existence of general truths and laws, to which the relation of things to, and their operation upon, each other conform. These laws or truths, ascertained by the investigation of men devoted to particular departments of inquiry, constitute a science. In all the different branches of knowledge different degrees of certainty are attained.

Generally those who appear in our courts as experts are volunteer theorists. The stake in the cases in which they testify is often enormous—it is life, liberty, or large estate—and the *temptations* are *made correspondingly strong*. A theory is to be proven and each party looks around for

some expert to prove such theories. Each party will call only the experts that will prove his case. For good and sufficient consideration there is no difficulty in finding a *ready-made* expert. Many honorable, worthy and able men of the profession have a horror of and shrink from attendance at our courts. For this courts are in a measure responsible. The self-respecting physician has no special relish for being badgered by an impudent lawyer.

An eminent jurist puts the matter in a strong light: "There is need of reform in our present method of giving expert testimony, which is rather calculated to embarrass than to aid courts in reaching a right conclusion, owing to the fact that experts are employed by the respective parties and almost invariably, though perhaps unconsciously, become partisans; and because they are accustomed to give unqualified opinions as to the mental condition of persons in answer to hypothetical questions which group together isolated acts of excentricity, incoherence or forgetfulnesss, whereas their answers should be qualified by the assumption that the facts supposed truly and faithfully represent the characteristic and conduct of the person suggested. For it was quite possible so to group his exceptional peculiarities of widely different periods, as to make the most sane of men appear to have been of unsound mind, whereas a right judgment required that the alleged peculiarities and exceptional conduct should be taken with his countervailing moral conduct and characteristics, and that their due significance should be assigned to each."

The respect which was once paid to the testimony of experts has diminished. Calvin, an eminent judge, says: "I think the opinions of experts are not so highly regarded now as they formerly were, for while they afford aid in determining facts, it often happens that experts can be found to testify to anything, however absurd." And yet another goes so far as to say: "If there is *any kind* of testimony that is not only of no value, but even worse than that, it is, in my judgment, that of medical experts. They may be able to state the diagnosis of a disease more learnedly, but upon the question whether it *had* at a given time reached such a stage that the subject of it was incapable of making a contract or was irresponsible for his acts, the opinion of his neighbors, of men of good common sense, would be worth more than that of all the experts in the country."

The profession will admit that there are grounds for the severity of these opinions. It is a fact that this kind of opinion is extremely unsatisfactory. The difficulty comes largely from the manner in which the witnesses are selected. While it is left to the parties to select their own expert witnesses, there will be two trained bands of expert witnesses against each other, since neither party is bound to produce, or will be likely to produce those as their witnesses who will not confirm their views. There are no theories so absurd that some unique philosopher may not be secured to testify that he believes it.

It would be somewhat embarrassing, if not a difficult question for a court to decide as to whether a witness offered as a medical expert was not a quack or speculative theorist and therefore inadmissable as an expert. Yet the trouble remains that very much of what passes under the misnomer of expert testimony is clumsy speculation. Under existing methods experts are open to the very serious objections, that they are unofficial persons selected by the party calling them because their pre-ascertained views will serve the party's necessities.

As a remedy for the present faulty and unsatisfactory method (as urged by one of our eminent judges) the courts should be impowered to appoint experts in the case,

to whom should be submitted the questions which should embrace a substantial statement of the facts as claimed to have been proven by the respective parties, and their answers taken upon the several assumptions. Then experts would not be subject to partisan "coaching," or tempted to assume the championship of either side of the case, but would stand indifferent, with nothing but their learning, their skill and their respect for truth to influence their opinion.

Such a method of expert examination would furnish the courts and the profession with a valuable collection of expert opinions on litigated questions, and certainly would add greatly to the weight of medical expert opinion.

It is a maxim of law that witnesses are not to be counted, but be weighed. It must be confessed that many of our medical experts are of light weight.

Where wealth or great interests are involved the temptation to almost any form of expert opinion can be made very strong. When required to give time and labor to the elucidation of questions on trial before our courts, the better opinion is that experts should be entitled to special fees.

# ABSTRACTS.

## THE CHOLERA IN CONSTANTINOPLE.

Prof. A. L. Long, of Roberts College, writes, (*Independent*):—For two years the reports from both Europe and Asia, in regard to the spread of cholera, had left but little hope that Constantinople, which had suffered so severely in former visitations, could escape. A rigorous system of quarantine was established and maintained during the whole season, and the gratifying result was that no authenticated case of cholera occurred in the city or its suburbs. This was considered a great victory by those sanitarians who advocate the quarantine system.

Again, in the spring of 1893, the season opened with cholera in both Europe and Asia, with increased mortality over the previous two years. By order of His Imperial Majesty the Sultan, the Sanitary Council proceeded at once to take measures for the defense of the capital. Quarantines were established by sea and by land. All arrivals from the Black Sea were quarantined at the entrance of the Bosporus, or else required to pass through under the yellow flag, and carrying a guard to see that no communication was made at any point with the shore. All arrivals from the Mediterranean were quarantined either at the Dardanelles or at Clazomene, near Smyrna. The land approaches were also well guarded. The through trains from Paris were stopped; and at the Turkish frontier there were erected huts, where all travelers were compelled, under strict surveillance, to pass a period of from five to ten days' detention, followed by fumigation and disinfecting processes of the most disgusting and often most indelicate kind. Remonstrance was of no avail. Serious injury was frequently caused to persons in delicate health by being almost suffocated in passing through the smoke box. Quarantine came to be more dreaded than the cholera itself.

The following incident will illustrate the strictness with which the quarantine regulations were carried out. An English steamer, passing down the Bosphorus, bearing the yellow quarantine flag, was run into by another vessel just opposite the village of Bebek and had a large hole punched in her side. With no little difficulty and danger she reached shallow water, and preparations had to be made for lightening her cargo and mending the great hole in her side. No one was allowed to leave the ship, although lying

within a stone's throw of land. The guard boat from the Quarantine Station soon arrived, and the cordon of soldiers in boats drawn around to prevent any communication with the shore. The workmen who came to repair the damage and the lightermen who came to take out a portion of the cargo all had to be considered as in quarantine. There was no case of sickness of any kind on board, only the vessel was under obligation to go through under the yellow flag; and even an accident was not to be allowed to relax the vigor of the law.

Notwithstanding these precautions, however, before the summer was fairly commenced there were some cases of sudden death in various parts of the city. The local newspapers at once received orders from the "Press Bureau" that no mention of the word *cholera* would be permitted, and no news of any sickness and death should be published, except such as would be officially communicated by the Sanitary Council. In all communications the term "suspected malady" was employed from a kind of superstitious dread of the word "cholera."

Suddenly, in the insane asylum—or, more properly, madhouse—in Scutari, some disease broke out which carried off more than eighty of the unfortunate inmates in one week. Probably the truth will never be known as to the cause of this outbreak. It may have been a case of poisoning from improper food. I have heard it asserted that a recently returned pilgrim from the holy places, having a relative among the insane patients of that establishment, obtained permission to visit him, and seized the opportunity of giving him some water from the Holy Spring which he had brought with him for that purpose. The miraculous water cured the patient and eighty or ninety of his companions by a speedy removal out of this world.

When it became evident that, whether cholera or not, some disease had made its appearance, the measures of precaution were increased. A specialist in bacteriology was summoned from Paris by imperial order, at a cost, it is said, of $20,000 and expenses; and he was asked first to determine whether this "suspected malady" was really the Asiatic cholera, and second to direct the measures to be taken for its extirpation.

After much talk, many meetings, examinations, microscopic and otherwise, fierce discussions, insinuations of charlatanism, accusations of imbecility, incompentency, mercenary motives, etc., it was decided that the disease was Asiatic cholera.

As the result of the deliberations of the council of experts, the whole city and suburbs were divided into sanitary subdistricts under the care of a special corps of doctors who were especially appointed for the work. Certain pharmacies were also named from which the necessary drugs were to be procured in case of need. The entire police force were also placed under the strictest orders to report immediately every case of illness of any kind whatsoever to these doctors, who were to be responsible for the entire treatment. All the pharmacies were ordered to report immediately every application for antidiarrheic medicines; and although the order was not actually issued, yet it was proposed to forbid employers giving their men any cholera medicines privately, lest cases might thereby fail of being reported and the work of disinfection be not attended to properly.

It was not very long before serious complaints began to be made by the people who were being terrorized over by the sanitary police, and were much more afraid of the police than of the disease. Very little, sometimes no attention was given to curing the disease; in fact, the patient was not expected to recover; but all efforts were directed to *disinfecting*. Stories were in circulation of most horrible treatment. A poor fellow was found lying in a corner drunk. The police came down upon him with their disinfecting apparatus. He protested that he was not sick, only drunk; but he was thoroughly saturated with carbolic acid, tumbled into a cart and covered with chlorid of lime and taken to the cemetery and buried, having been suffocated by the disinfectants.

Some of the scenes enacted upon the streets were worthy of the pencil of a Nast. A poor fellow is seen lying on the ground, not dead, but in a comatose state. A ring of soldiers is formed around him at a distance of a few yards, while behind them at a safe distance are standing two young doctors with eyeglasses, inspecting the case and noting down the facts in their note-books, and two sanitary servants

under their direction are lying down on the ground a ring of chlorid of lime around the patient as an effectual bar to any straggling microbes.

Many cases occurred where invalids not suffering from any like cholera were reported to the authorities, who, without investigation, sent soldiers to form a cordon round the house, and forcing their way in with their formidable apparatus, have frightened the patient to death, then burned up and destroyed the bedding and other clothing, and sent off the corpse to a hurried burial without the observance of any religious rites. This, of course, was not to be tolerated very long. The religious sense of the Moslem population was shocked and they found, at length, the means of reaching the ear of the Sultan, who was honestly trying to do everything in his power to avert the pestilence from his people. An official proclamation was accordingly made to the effect that all were to be permitted to call any physician of their choice, that any barbarities or extortion practiced by sanitary agents was to be reported for punishment, and that no burials were to be made without the consent of friends and every facility having been given for customary religious rites. This wise and humane proclamation from His Majesty had a very good effect in quieting the excited populace and securing a rational treatment of the epidemic.

The number of cases gradually diminished, until at length the specialist was dismissed and the most of the sanitary agents were also discharged. The enormous bills for chlorid of lime and carbolic acid, etc., were sent in and paid, and the public generally were breathing freely, and comforting themselves with the thought that the epidemic was finished. Within the past few weeks, however, the unwelcome guest has again made its appearance. Although the official reports give the number of cases as very small, it is rumored that the mortality among the military is serious, and that some seventy cases have occurred in the Imperial Guard. If this be true, it is very greatly to be feared that we shall have a severe visitation the coming spring and summer.

As to the question of the effectiveness of quarantine, the balance of evidence seems to be in favor of a rational and scientific quarantine.

As to disinfection, the great difficulty is to have it intelligently done. Processes which in veterinary practice have been found effective in stamping out the cattle plague are not admissible with human patients, but may result in a cowardly selfishness more deadly in its effects upon society than any pestilence.

## CASE OF LITHOPÆDIAN.

Dr. Oker Blom reports in *Duodecim*, a Finnish medical journal, a case of lithopædian, which was followed by normal pregnancy.

The patient was a women forty-two years of age, whose fourth pregnancy ended in pains for three days without any expulsion. After a time a tumor the size of a head could be felt in the abdomen. Three years later she again became pregnant, and in due course was delivered of a healthy male infant; the tumor, however, remained, and as the abdominal walls were very thin, its outline could be distinctly felt, the right hand with its fingers as well as the left hand being made out without any difficulty; the two forearms were flexed at right angles to the elbows and were fixed, but the humeri could be moved in the shoulder joints. The uterus presented the usual characters of the organ in multiparæ.—*The Lancet*, 1894.

THE magazines are cutting their prices in two and some of them are suspending. In these times of financial depression the only magazine that goes off with a boom is *the powder magazine.*

MANY people cannot be forced to believe anything that they do not wish to believe.

## OPERATIVE TREATMENT OF ENLARGED PROSTATE—LAMINECTOMY IN SPINAL INJURIES.

Before the Surgical Section of the Royal Academy of Medicine in Ireland, Mr. Arthur Chance read a paper on the Operative Treatment of Enlarged Prostate. He referred to a man aged fifty-six years, on whom he had operated by the supra-pubic method. Electrolysis had first been tried, but gave only temporary relief. The growth showed the "uniform circular enlargement surrounding the internal orifice of the urethra."

Prior to the operation the urine had been passed on an average every ten minutes; but now, more than ten months after the operation, the man could hold his urine with ease for ten or twelve hours. Mr. Chance considered that a catheter did not completely empty the bladder, and that, therefore, the usual method of estimating residual urine was open to fallacy. He advocated the use of a flushing gouge for the removal of the growth, for the reasons that it could be readily manipulated through a small incision, and also because of the value of a stream of hot water in stopping hemorrhage. He thought the supra-pubic drainage really meant overflow, and he, therefore, advised the insertion of a perineal tube as an addition to the supra-pubic operation. In conclusion he strongly urged the propriety of early operation.

Mr. Kendal Franks congratulated Mr. Chance on the success attending this case. He entirely agreed with him as to the value of supra-pubic drainage, but he thought that where they had a healthy perineum they should deal with it there, because it was putting the drainage in the most dependent position. Mr. Wyles thought the paper presented a subject of the greatest importance and difficulty. His own experience was that the diagnosis of these cases was not at all simple. Mr. Chance in reply to Mr. Franks said with regard to the closing of the bladder, that the probability of failure would be very much diminished if perineal drainage was employed, because there would then be no strain on the bladder. He admitted with Mr. Wyles that the difficulty of diagnosis was great, but he always adopted the precaution of first reducing inflammation by mild measures, and he thought that after that, the age and symptoms would lead them to a right conclusion.

Mr. T. Wyles then read notes of a case of laminectomy for spinal injuries, in which a man who had been admitted to the Richmond Hospital for paraplegia, the result of a fall from a cart on to the back of his head, had been operated on by him. The symptoms that were held to justify the operation were the presence of motor paralysis—complete in the case of the legs, incomplete in the arms—persistance of cutaneous sensibility, and the existence for twenty-four hours of reflex irritability in one lower limb. Mr. Wyles described the operation and the fatal termination of the case, and discussed the phenomena associated with these grave injuries, pointing out that it was only in fractures caused by direct violence that any reasonable hope of benefit by operation existed. Mr. F. A. Nixon, said that the operation was performed with great manipulative skill, and the cord on exposure seemed to him to be intact, and surrounded by its normal coverings. Mr. Doyle and Mr. Kendal Franks also spoke. Dr. J. Barton inquired as to the condition of the cord on making a post-mortem examination. Mr. Wyles, in reply to Dr. Barton, said, that no microscopic examination had been made, owing to the specimens having been mislaid. The cord had the appearance of being slightly bruised and flattened, but its continuity did not appear to be disturbed. He had hoped that the physiologists would be present, as he thought they might enlighten them regarding the process of evolution, which the physiology of the spinal cord was undergoing at present, judging from experiments on animals. It seemed to him that the clinical value of the spinal reflex was misunderstood.

---

A WOMAN rather enjoys having you love her while conscious of her faults, because this is the triumph of her fascination over your reason; but a man cares little whether you like him or not, provided you acknowledge his superiority.—Manley H. Pike, in *Kate Field's Washington.*

---

TELL nobody what you are going to do, keep silent while you are doing it and say nothing about it after it is done.

## MALIGNANT ENDOCARDITIS—THROMBOSIS OF THE PORTAL SYSTEM.

Mr. Burgess read a paper on a case of malignant endocarditis in a married woman, aged thirty years, who was six months pregnant. The chief interest lay in the obscurity of the case from the first, and likewise that it differed from the description of recorded cases in its symptoms. The prominent symptoms were pain of a lightning character, shooting in paroxysms from the inside of the knee to the base of the abdomen, and a fixed pain at the symphysis pubis; there was also, after a time, paralysis of the bladder. The temperature was 101° F., and a murmur was apparent from the first in the mitral valves, substituted in character.

Miscarriage took place on the seventh day, but as the sequelæ gave rise to no fresh symptoms, it was not regarded as a complication. On the 18th day embolism of the left cerebral artery occurred, followed by rapidly increasing coma and death on the 20th day.

The remarkable points were: 1. Murmur, which was present from the first, with an absence of any previous history of rheumatism. 2. The nervous phenomena, which were the distinct features. 3. The temperature, which was of the continuous type. 4. Its already alluded to difference from the ordinary forms of pyæmia-cerebral, cardiac or septic. 5. No occurrence of emboli took place until the 18th day, and there were no signs of renal or splenic embolism the whole time. 6. The peculiar absence of perspiration. The treatment was symptomatic. Dr. Tweedy and Dr. Moore commented on the difficulty that frequently existed in making an early diagnosis with accuracy. The president then related a case of thrombosis of the portal system in a man aged thirty years. He was anæmic, the legs were swollen, but there was no albumen in the urine, either then or subsequently. Some months later he was admitted into hospital for severe abdominal pain, which had developed thirteen days previously. He was very weak and sallow, and suffered from dry retching. The abdomen was distended and tender. It was dull at the lower part and sides, and fluctuation could be detected; there was no enlargement of the cutaneous veins. A systolic murmur was heard over the heart, at the base and apex. The bowels were loose and there was pyrexia. He became worse and died in collapse after a week's stay in hospital. Post mortem, the liver was found to be normal in size, very hard and tough, with nodular cirrhosis, especially on the under surface of the left lobe. The gall-bladder was flaccid. About two and a half quarts of thin serous fluid escaped from the peritoneum. The spleen was enlarged and firm. The portal vein was adherent to structures in the transverse fissure. It was much dilated, and its coats were thick (about three m. m.) and leathery—not calcified. Its interior was occupied by a firm, yellowish granular thrombus adherent at one side to the veins, but not completely obstructing its lumen. The branches of the portal vein through the liver were filled with soft thrombi, closely fitting, and yet capable of being withdrawn. The mesenteric veins were occluded by soft red thrombi. The jejunum for about one foot was adherent to the ascending colon by soft recent lymph. There was acute recent peritonitis over the liver and over this portion of the bowel, which was intensely congested and nearly black, resembling a strangulated intestine. There was no blood in its interior; the mucous membrane was eroded. The walls of the rest of the small intestine were much thickened by œdematous swelling. Several veins near the pyloric end of the stomach were firmly thrombosed. Pleural adhesions existed on each side, and there was effusion into the right pleural cavity. The probable order of events was: (1) Cirrhosis of the liver; (2) thrombosis of the portal vein; (3) sudden extension of the thromboses to the gastric and mesenteric veins; and (4) peritonitis.—*The Lancet*, 1894.

# SOCIETY REPORTS.

## THE LOUISVILLE MEDICO-CHIRURGICAL SOCIETY.

*February 22nd, 1894.*

[Stenographically Reported by C. C. Mapes, M. D.]

### CASE OF MICROCEPHALUS.

J. L. HOWARD: This child is aged three and a half years, and presents a typical case of microcephalic condition; he does not notice anything, cannot walk, cannot talk and has epileptic convulsions nearly every day. He has had as many as two or three in a night. I simply brought the case in connection with one shown by Dr. Vance at the last meeting of this society. It might be well to state that the mother of this child had a fright at about the fourth month of pregnancy, an occupant of the house having had a convulsion in her presence.

### CASE OF EPILEPSY.

No. 2.—This girl is twelve years old; family history very good; she had never been sick with the exception of measles, in July, 1893, and her present trouble which is epilepsy. The first convulsion occurred when she was eight months old, and the seizures continued with considerable regularity for five years. She gradually grew worse; the convulsions coming on at shorter periods. For three years subsequently, that is after she was five years of age, she was free from any attacks and remained so until recently. They have come on again greatly increased in severity and she was put under treatment. She first came to me, and was afterward treated at the University Clinic. The treatment had been bromide of stramonium. The mental development seems to be more marked than we would expect. She has attended school this winter, and while she seems bright enough to look at, they have been able to do very little with her at school.

### DISCUSSION.

DR. A. M. VANCE: I think the microcephalic case exhibited by Dr. Howard belongs in the same category, as the one I showed two weeks ago. Case of microcephalic skull with spastic symptoms. I believe that the operation that is being done for this condition, as I said at the last meeting, is no longer warranted by experience and ought to be obsolete; that of craniectomy or craniotomy.

### OSSIFICATION OF THE CHOROID.

DR. WM. CHEATHAM: This specimen is an eye that I removed last week. I think it is the most perfect ossification that I have ever seen; the so-called ossification of the choroid. The degeneration extends as far forward as the choroid. While this condition is called ossification of the choroid, you will observe that the ossification is between the choroid and retina. There was no history of trauma in this case, and the trouble was referred to a rheumatic attack in early life. One strange thing about the case, is that in the family there are three men bearing identically the same name, each man has only one eye and that is the left eye.

### DISCUSSION.

DR. S. G. DABNEY: The specimen shown by Dr. Cheatham illustrates the dangers to which a good eye is exposed by the presence of a blind one, even after years of blindness. I exhibited several years ago to this Society an eye which had been lost also without any trauma; the eye had been blind for many years just as in the case reported by Dr. Cheatham. In this case the ossification did not extend far enough forward to be very well felt on palpation, so diagnosis was not made until after the eye was removed. The patient was a man and attention was attracted to his blind eye by its sensitiveness to pressure. There were also symptoms of sympathetic irritation in the other eye which disappeared on the removal of the offending eye.

### CONTINUED REPORT—FIBROMA OF THE URETHRA; OPERATION.

DR. T. S. BULLOCK: At a meeting of this Society some months ago, I read a paper on the subject of "Tumors of the Urethra" and exhibited a female patient having such a tumor. I operated upon the case one week ago last Wednesday, and present here for your examination the tumor removed. The only point of interest is, that in the former discussion of the subject there was a difference of opinion as to whether it was a fibroma of the urethra or of the space between the urethra and the ostium vagina. Some of us took the ground that there was no such space from an anatomical standpoint, and the removal of this growth clearly demonstrated that it was attached to the posterior semi-cir-

cumference of the urethra. It was very easily and quickly removed with an ordinary scalpel; there was little hemorrhage and no after effect whatever. The specimen is of interest from the fact that I believe none of the members at the time the case was exhibited had ever seen a fibroma in just this situation.

---

FOREIGN BODY IN THE LUNG.

DR. D. T. SMITH: I merely wish to present for your examination this piece of metal, a gold collar button weighing about forty-five grains, which remained three years in the apex of the right lung of a little girl, causing some inconvenience, some pain, especially centering there when she caught cold, but without any other disturbance. Since she coughed it up she has recovered from that condition, and is entirely well.

The case illustrates the fact that foreign bodies may remain in the lungs for a long time with comparative safety. It has been commonly thought necessary to remove such objects at once by tracheotomy.

DISCUSSION

DR. J. A. LARRABEE: In regard to the specimen exhibited by Dr. Smith, and the innocuousness and harmlessness of such bodies, a much smaller specimen than this produced death indirectly in a case that I saw after three years. I performed a post-mortem and found a small rivet, such as is used in fastening the edges of stove pipes together, in the right lung. It had passed down into the right bronchus, thence entering the bifurcation of the lung. The child died of croupous pneumonia. The rivet acting as a foreign body I think played an important part in the cause.

I merely mention this case to emphasize the fact that these bodies are not so harmless as we might be led to infer from the very fortunate result in Dr. Smith's case. In the case I have incidentaly referred to, the patient who swallowed, or was supposed to have swallowed this rivet, remained three years under treatment for obscure lung trouble, and finally died. At the post mortem the cause of the trouble was ascertained. An interesting feature in the case was that the croupous membrane extended into the bronchial tubes of that side only.

DR. Cheatham has just called my attention to another case I saw some time ago, in which a shell of a peanut was accidentily drawn into one of the bronchi, resulting in death in five days. So that foreign bodies although they may be much less in size than the one shown by Dr. Smith—which is very interesting because of its being divided into two parts—may result seriously, and should not be regarded by any means as harmless. Dr. Smith's case is certainly exceptional, and I do not think we ought to expect to see so happy a result from such accidents.

DR. STONE, of Hopkinsville, (visiting); In regard to the innocuousness of the presence of foreign bodies in the lungs, I would like to mention one case, and hear the subject discussed at greater length. A child from near Hopkinsville was sent to Nashville, Tenn., to be operated upon about two weeks ago, and the doctors there removed a grain of corn from a point just at the bottom of the trachea. It had passed through the trachea down to the bifurcation of the bronchi. Would it have been proper to have left that child without operation for any length of time? Would there not have been some danger of suffocation? In other words was operation for removal of the grain of corn demanded, or could the child have recovered without it? I will state that since removal of the foreign body, the child has made a very happy recovery.

DR. WM. CHEATHAM: In reply to Dr. Stone—several cases of the character he mentions—six or eight, at least—have occurred in Louisville within the last few months, where tracheotomy has been performed for the removal of foreign bodies from the trachea. I think all of them should be removed through the trachea at once, and especially grain of any kind which is so liable to increase in size by swelling as it becomes moistened.

DR. A. M. CARTLEDGE: I think Dr. Smith is entirely too modest in requesting that his case be not discussed. My own experience to a certain extent bears out the assertion of Dr. Larrabee in regard to leaving some of these cases alone. I have had three cases of foreign body in the trachea; in one the foreign body, a piece of corn stalk, was expelled after four or five months; I did a tracheotomy and kept the wound open for eleven days, but the foreign body did not come up, but was eventually expelled. In another case the foreign body was a tack; a tracheotomy was performed, but the tack was never found. A tracheotomy in the third case was done and a grain of corn was readily removed. The statistics, as Dr. Cheatham suggests, do not bear out the harmless character of foreign bodies in the trachea. No matter what the character of the foreign body is, the proper thing is to do a tracheotomy, and if not found at once to keep the wound open a reasonable length of time in the hope that it may be expelled. It seems to me very remarkable that the foreign body in Dr. Smith's case passed up through the vocal cords. The probabilities are that an abscess formed, which eventually broke and the piece of metal was expelled in that way.

Dr. Wm. Bailey: One point of interest occurs to my mind from the discussion by Dr. Larrabee, that is the possibility of foreign bodies producing or creating *croupous pneumonia.* Whether it is possible for either trauma or the irritation of a foreign body in the air passages to produce or cause *croupous pneumonia* which is perhaps a *specific disease,* it occurs to me would be a very difficult question to decide.

Dr. J. A. Larrabee: In speaking of *croupous pneumonia* I should have said the production of *croupal membrane* in the air passages. I believe that the irritation of the foreign body in the bronchus was an important factor in producing croupal membrane in the air passages, but of course it did not directly produce *croupous pneumonia.*

Dr. Wm. Cheatham: Dr. Vance and myself had a case some years ago in which a man was eating what his wife called "Noodle Soup" and accidently, a piece of bone as large the end of my thumb, was taken into the throat passed into the larynx and thence into the left bronchus. We performed a tracheotomy, and kept the wound open several days but the foreign body was not expelled. Dr. Krim six months afterward exhibited the piece of bone to one of the Societies, it having been coughed up even after the lung had become gangrenous. The left lung was found to be perfectly gangrenous, yet the man had forced this foreign body up through the larynx six months after it had been taken in.

Dr. D. T. Smith: I did not mean to say the presence of foreign body in the lnngs should be regarded as harmless, but the popular notion is or has been, that if a foreign body gets into the lung, if it is not immediately removed the result will necessarily be fatal. There is a very general impression among the people that such an accident is fatal in its results. Tracheotomy is by no means a dangerous operation, and in all cases where the foreign body is a bone or grain of any kind which is likely to swell or decay I believe the proper thing to do is to make an effort to remove it. I remember a case where a piece of ginger remained in the throat of a boy (he was a man when it was coughed up) for thirteen years. He was a man in fair health when I knew him, which was after the foreign body had been expelled; his lungs had remained weak and he was subject to occasional hemorrhages from the spot where the ginger had been lodged.

I happened a few days ago, since I received this specimen, to be looking over a German journal and noticed a list of quite a number of cases similar to this which had recovered without operation. One of them, strange to say, where a set of false teeth had passed over the epiglottis during sleep and had lodged in the vocal cords, and remained there for several months unsuspected. This was afterward removed and the person recovered. Of course it did not reach the lungs. When the foreign body consists of pieces of gold, silver or something that will not decay, I think the danger is very much less than is popularly and generally supposed even by the medical profession. I merely make these statements as a source of hope to those who may have foreign bodies in their lungs, that the result is not so dangerous from their being left there as is commonly supposed.

---

The essay of the evening was by Dr. J. A. Larrabee, on the subject.

EPILEPSY

(See page 447.)

DISCUSSION.

Dr. J. B. Marvin: All of Dr. Larrabee's papers are interesting, and the one we have just listened to is no exception. There are one or two points that I would like to mention. He tells us of the number of cases he has had where cures have been effected; he does not tell us the number of cases treated during the same length of time which were not cured. The number that he has cured, if I understood him correctly, by methods not generally recognized as being most beneficial in therapeutics, struck me with some degree of force. The history of epilepsy is so well known, as he indicates, and the therapeutics are so extensive, and the profession as a whole have had such bad results with these metal salts, that when the bromides were introduced the effects were so much better that the majority of the profession rather looked upon bromides as specifics. Reaction has come on, the pendulum is swinging the other way, we now know that the bromides are not specifics. Certainly the statement that ninety per cent. of certain cases of epilepsy are amenable to large doses of silver salts—to the point of toxicity—long continued, is startling. I think this statement will be borne out by statistics if we can rely upon them, that a greater percentage of cases of epilepsy are benefited by the administration of bromides than any other single or combined remedy. Another thing, I think in those cases where we do not get the marked acne from bromides, the treatment shows better results than the converse. I believe also that this statement will be borne out—that there is a way of giving the bromides without producing all of the ugly and detrimental effects as pictured by some authorities, so that it is perfectly possible to give the patient bromides to the point of tolerance without producing mental hebitude, cachexia

and gastric and cardiac depression. This subject to my mind has about resolved itself at present into two classes: One class who look upon epilepsy from a medical standpoint and who continue to drug it. That class can be sub-divided into the surgeons who operate for the traumatic cases. There is a tendency now in the other class to do away with medical treatment, bromides and every other form of treatment, and claim that all of these so-called phenomena of epilepsy are due to peripheral irritation, and a great many operations have been performed, especially about the eye for correction of so-called muscular strain, and they claim to get better results than by any internal medication. Taking this view of the situation, if epilepsy is produced by long continued peripheral irritation, is it not more rational to remove that peripheral irritation by some operative procedure rather than to give some internal medication to attack the cerebral centres which is almost certain to keep up the peripheral irritation?

I have long since come to this conclusion, that if I had to choose between the bromides, or any other form of medication, and simple regulation of diet and the bowels, I would take the latter in preference to the former. There is certainly no question in my mind but many cases are dependent upon gastric indigestion, retained fecal matter, toxæmia, or whatever you may choose to call it, and by getting that part of the system in an aseptic and healthy condition, we can sometimes accomplish more good than by keeping the patient thoroughly under the influence of the bromides. There is another point just there that I cannot settle, bearing on the latter subdivision that I mentioned, which is agitating the profession at the present time; namely that of operations upon the eye and other organs whichever might be supposed to be the exciting reflex cause. It is a fact as we all know that the nervous system especially tends to perpetuate certain actions; a spasm occurs to-day or maybe two; it comes on more easily to-morrow, the next day still easier, and so on. If you will take a frog, get him to remain quiet and stroke his back gently, he will manifest signs of pleasure. You may excite his sexual desires and he will exhibit all the manifestations of pleasurable sensation. If you will take that frog and remove his cerebrum he will still live, and after he has recovered from the primary shock you can still by the same stroking of the back excite exactly the same motions. Now that is the important point: If it is so, and it certainly is, there must be two factors in the production of epilepsy. Certainly after the first attack, whether from peripheral irritation of the eye, stomach, penis or any other organ, there is that condition of the brain which renders the subject more susceptible to ordinary peripheral irritation. Now the practical point is if that is so will we get good results in cases of long duration by simply correcting the peripheral irritation? Will the habit not already have been formed, and the tendency be to keep it up? It is questionable in my mind whether epilepsy is curable by tenotomies, prisms, etc. about the eye.

Bromides may be given for a long time without any bad effects, and I think the majority of authorities differ in regard to the best salt. The ammonium salt is perhaps a little more stimulating and rather less depressing, but I think the best results are obtained from the bromide of potash.

I have had some cases under observation for four years without any return of epilepsy; in other cases the attacks have returned after a few months.

DR. D. T. SMITH: A more interesting subject could hardly be introduced for discussion than epilepsy, and I am sure not a more profitable one could have been selected. My experience, which has not been so great as that of Dr. Larrabee, has been all under authority; I have never departed from the ordinary routine treatment, therefore can say but very little except what has been gained from the experience of others. As Dr. Larrabee says the disease has been present in the human family from time immemorial, it is recorded by the earliest writers, and for years it was regarded as being a production of devils. This was generally believed, and in order to treat it successfully it was necessary for the operator to be able to practice the extirpation of these devils. Josephus claimed, if you will remember, a man in his time who practiced this by drawing them through the nose of the patient; that this could be seen by the natural eye, and as evidence that this man could draw the Devil through the nose of the patient, the epilepsy was cured. Of course the result was entirely due to some mental effect produced upon the patient, and as he believed that the Devil had actually been drawn through his nose, or the cause of his epilepsy if you please, the result was that he was entirely relieved.

In regard to the pathological condition, the causation of epilepsy: Many writers claim that it is a vaso-motor spasm. I think if anything has been disproved it is the contention that epilepsy is due to vaso-motor spasm. I think it is settled with reasonable certainty, that as far as we know, and we can go no further, that the cells have an accidental or premature discharge of force, and this is the active factor in the production of an epileptic attack.

In regard to peripheral influences: I took occasion in the last paper I read before this

Society to deny, on the authority of Dr. Landon Carter Gray, any relation between the production of neuroses and the production of epilepsy. Gowers as well as Gray also states that the cases are exceedingly rare where peripheral influences have anything to do with the causation of epilepsy. One case was reported where a scar on the finger was believed to be the cause of the epilepsy; and in which the amputation of the finger cured the epilepsy. Other similar cases are reported, but the general opinion of neurologists is that a neurosis is present and that growths, scars, or peripheral irritation act merely as the exicting agents. If it could be demonstrated that the exciting cause of a case of epilepsy was a spicula of bone, then it would seem reasonable that its removal might effect a cure; on the other hand some change might have been brought about in the neighboring nerve cells which would cause a continuance of the seizures even after the offending substance had been removed.

Referring to Dr. Larrabee's statement as to the avoidance of meat in epileptics: That meat food acts as a preventive of epileptic attacks has been demonstrated beyond peradventure in a certain proportion of cases. Gowers especially recommends that meat be given in such cases.

DR. T. H. STUCKY: I would like to ask Dr. Larrabee if he has ever used the bromide of gold and arsenic in the treatment of epilepsy. At the last meeting of the Mississippi Valley Medical Association, I listened to a very interesting paper read by Dr. Wood, of Pittsburg, Penn., who presented me with a two ounce sample bottle of this preparation made by Hayes after the formula of Dr. Barclay. At that time I happened to have a little girl under treatment for epilepsy, who was having from three to five attacks per month. I took her to the clinic that day and she was placed upon five drops of the bromide of gold and arsenic, gradually increasing the dose until the effects of the arsenic began to show itself in puffiness of the eyelids, etc., then the quantity was again reduced to five drops. She has been kept upon this dose without any return of the epileptic attacks. Whether the result is due to the curative effect of the bromide of gold or the combination I am not prepared to say. I am inclined to believe the latter.

I have had one case under observation since 1886, nearly eight years, under the constant use of bromide not carrying it to bromism but to the point of tolerance for a period of nearly two years, and there has been no return of the epilepsy up to this time.

DR. H. A. COTTELL: Epilepsy is a thoroughly worn out and threadbare subject, and I doubt very much if there is anything new to offer upon it. When I took charge of the clinic at the University two years ago, a great number of epileptics presented themselves, old and young, and almost every known remedy for this affection was tried there. About this time bromide of stramonium came into notice and was attracting considerable attention, and I gave this remedy a thorough trial at the clinic. The results were seemingly satisfactory. But this is the old bromide treatment over again. The only argument that can be made in favor of bromide of stramonium over bromide of potassium and sodium is that the stramonium salt has a molecule which carries two atoms of bromine, while the others have a molecule which carries only one. Thus the potassium salt is K Br1, while the stramonium salt is SrBr2. A point in in favor of bromide of stramonium is that we can get the patient a little more rapidly under the influence of bromine with it than with the other remedies. I do not believe that there is any remedy for epilepsy. Even nitrate of silver will not cure it, though I am quite sure its continued use will make the patient resemble the polished stove pipe so pertinently described by the essayist.

I have never cured a single case of epilepsy.

DR. D. W. YENDELL: Concerning the pathology of epilepsy: The essayist spoke of how little we knew about it, which I readily admit to be the fact. In all my experience I have only made three *post mortem* examinations for epilepsy. One was when I was connected with the Medical Staff of the City Hospital, on a confirmed epileptic who had been made blue by nitrate of silver. It was before the days of bromides. Bromides did not come into use until Locock brought them prominently before the profession in 1862. In one case where I made a *post mortem* the membranes of the brain were found to be studded with hydatid cysts; there could not have been less than fifty or sixty of them scattered throughout the brain, varying in size from a shot to a hazelnut. Another case was one of traumatic epilepsy, where a man had been stabbed with a pocket knife. There was a little scar, when he came into the Hospital, just at the inner canthus of the eye. The knife blade had been broken off smooth with the soft parts; it had suppurated and a scab had formed over the wound. Of course it had not wholly cicatrized, and there was still a small open wound covered by a scab. The man died in an epileptic convulsion, and in taking off the calvarium, just inside and above the eye there was a considerable abscess filled with pus, and containing the piece of knife blade. The knife remained there in the man's head for over a month, causing repeated epileptic convulsions and finally death. These

are the only two contributions to the pathology of epilepsy I have to offer. The third *post mortem* was in the person of a child, where nothing out of the usual order of things was found.

In reference to the treatment of epilepsy; I have had no experience with the use of the metals Dr. Larrabee has spoken of. There are two great factors in the therapeutic management of this affection; first, attention to the diet; next, the use of the bromides to the full point of tolerance. I think I can say with perfect truth that I have seen a great many cases of epilepsy both in children and in adults entirely cured. I think anyone can fairly be called cured who goes without a seizures for a period of five years. I know a number of cases that have gone without any species of seizure whatever for five years, and several who have gone for ten, fifteen or twenty years without any recurrence whatever of a seizure.

I do not see any material difference in the relative value of the several bromides as between ammonia, potash or soda, sometimes I use one sometimes another. But before giving the bromides in any form I ascertain the sensibility of the fauces, and throughout all the time I am giving them, I frequently test the sensibility of the fauces—my object being to fetch about anæsthesia of the fauces in a short time, in a word to bring about complete anæsthesia of the fauces, so complete that, indeed, the finger can be passed all round the palate and tonsils without producing gagging; when the individual does not gag we may then be pretty sure that he is sufficiently under the influence of the bromides, and we should endeavor to keep him just at that point. I think this is a very important point in the administration of the bromides. I usually follow a suggestion made many years ago by Trousseau. I combine atropia—he used belladonna, along with the bromides. Where I do this I push the atropia to its full effect, and generally give it as long as I use the bromides.

DR. WM. BAILEY: I want to be recorded as believing, and my firm conviction is, that in the bromides we have more control over epilepsy than by all other means combined. I think these cases ought to be kept on bromides properly diluted. Twenty to thirty grains, three times per day, is usually sufficient to control convulsions, and this treatment should be kept up for at least two or three years. I have had such good result from the use of bromides in the treatment of epilepsy that I rarely give anything else. I think in favor of the fact that there is a vaso-motor spasm, there is one remedy which administered just at the time of the aura will sometimes arrest the paroxysm, and that is nitrite of amyl. I simply offer this as an argument in favor of vaso-motor spasm.

DR. WM. CHEATHAM: Referring especially to Dr. Marvin's remarks in regard to epilepsy dependent upon peripheral irritation: Section of the eye muscles has not resulted in the benefit that was promised by the originator of the operation (Stevens). Several cases were submitted to him by (I think) the Ophthalmological Society, of New York, and he was given three years in which to cure them, by tenotomy, etc. It is useless to say that he failed in the majority of cases, so that tenotomy of the eye muscles has not resulted in the good promised.

DR. STONE: I know of several children that have been entirely relieved from epilepsy and there is no question but quite a number of cases occuring in children are *cured.* I also know of several men who have gone four years to my knowledge at the Asylum without an attack, who were not only epileptic but maniacal. I also know of one such result occurring in a female adult outside of the Asylum. This length of time seems to me sufficient to be called a cure.

The pathological evidences often show plainly that it is impossible for us to cure all cases of epilepsy even though they are not traumatic. For instance an autopsy made at the Asylum showed a spicula of bone growing down into the brain, an exostosis about three-quarters of an inch in length, from the inner surface of the cranium. In another autopsy at the Asylum ossification of one of the arteries centrally located was shown to be the cause of the epilepsy. In neither of these cases could the real cause have been ascertained during life, and we could not have expected to relieve the trouble by any manner of treatment or medication.

At the Asylum we use the bromides exclusively, preferring them to anything else; although I have used other remedies, it has been to a very limited extent. Our results in the management of most cases of epilepsy have been unsatisfactory, merely ameliorative.

DR. P. F. BARBOUR, (Visiting): I am sorry to say that I have not had such favorable experience with the treatment of epilepsy as to warrant my hoping very much for it. My experience has been mostly in Asylum life. Under the largest doses of bromide of potash we were unable to do anything with them. It seems to me that the only cases for which there is any hope are such as are found to be dependent upon peripheral irritation. If we can remove the source of irritation whatever it may be, we can look for some benefit.

I was struck with the remarks of Dr. Larrabee concerning the effect which a change of physicians was likely to produce in patients suffering from epilepsy. Really the only ra-

tional treatment we have for the epileptic is to do something that will divert his mind and thus inhibit the action of the reflexes.

I think this is why benefit is derived when a new physician takes charge of the case; it is something new for the patient to think about; it is the impression made upon him by a new physician and a new form of treatment that produces the good results. If a doctor has been treating his patient with bromides and changes to something else, the patient for a time will do wonderfully well under the new treatment. It is through the inhibitory action upon the brain fibres that the bromides secure good results. It seems to me on chemical grounds that bromide of sodium is the bromide we should use. Sodium is one of the normal constituents of the body, and can be given for a long time without producing any of the disagreeable effects that sometimes follow the administration of bromide of potassium or ammonium.

I have never given nitrite of amyl as suggested by Dr. Bailey at the beginning of an attack, but its use is indicated if we are able to see the patient just at the proper time.

DR. J. A. LARRABEE: Perhaps some explanation is necessary as to the number of cases that have fallen under my observation. I reported them as cures, some of them extending over a period of eighteen years. All the cases have been carefully followed, with the exception of the one in California, and I heard from him only a year ago, bringing that down to within a year's time with no recurrence of the epileptic seizures. I am far from claiming a cure in one year or two years time, but if a man or child has epilepsy, three, four or five attacks in a month, and then after treatment goes five years without recurrence of the trouble, I think it is entitled to be regarded as a cure, whether the patient may again develop epilepsy or otherwise. Of course, I recognize the truth of Hippocrates' statement which has so often been verified, that this disease is curable in the young but not in the old. Most of my cases have been in the young, which is a point I wish to emphasize.

Dr. Marvin has probably illustrated this subject better than any one else, and has touched upon a favorite idea of mine in speaking about the perpetuation of epilepsy by the impression made upon the nervous system, rather by the photographic process upon the brain, and I wish to thank him for the elucidation.

Several of the cases treated by me with the metal salts had been under treatment by the bromides and various other remedies without benefit. There is nothing particularly new in the treatment I have mentioned. As stated in my paper I believe the good results from the metal treatment are derived from storage in connection with the nerve cells in the discharging areas of the brain.

I have never had any experience in the use of bromide of gold and arsenic mentioned by Dr. Stucky. My report contains or includes a large number of cases and a very large and varied experience, Some one has asked the question as to how many patients treated in the meantime and not cured: A great many cases, perhaps five or six, have passed out of my recollection entirely, ceasing treatment while they were having spells. I do not know what has become of them.

With special reference to the dietetic treatment: One of the cases reported by me illustrates very clearly the effect of diet upon epilepsy.

**From the Diary of a Quack.**

Kase 230, Mary An Perkins. Bisnes, wash-woman. Sickness in her bed. Fisik, some blue pils, a soaperifik; aged 52. Ped me one dollar, 1 kuarter bogus. Mind get good kuarter and mak her tek mo fisik.

Kase 231, Tummes. Krinks Bisnes, N Irishman. Lives with Pady molonny whot keeps a dray—Sikness digg in ribs and two blak eys. Fisik, to drink my mixter twice a day of sasiperily, bere and jellop, and fish ile, with asifedity to make it taste fisiky. Rubbed his face with Centaur Liniment. Aged 39 years of age. Drinked the mixter and wouldn't pay me bekase it tasted nasty, but the mixter'll work his innards, I reckon.

Kase 232, old Misses Boggs. Ain't got no bisnes, but plenty of money. Siknes all a humbug. Guv her sum of my celebrated "Dipseflorikon," which she sed drank like cold tea—which it was too. Must put sumthink in it to make her feel sik and bad. The Old Wommen has got the roks."

---

THE value of vaccination is now fortunately forced into universal recognition abroad by the striking statistics showing the marked difference in fatality between those European nations which make it optional and those which do not. Recent official recognition at home includes the summary action of the Boards of Health in Illinois and Wisconsin, where all school teachers and pupils must be vaccinated, failing which school privileges will be denied them; while in Iowa compulsory observance of Jenner's discovery is enjoined on every person.—*The Outlook.*

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

AMERICAN JOURNAL OF OBSTETRICS

for March contains a paper by Dr. Grace Peckham-Murray on the

**Mechanism and Treatment of Procidentia Uteri.**

The author presents the following summary of her views:

I. The pelvic floor has little to do in causing complete procidentia. The proofs of this are: 1. It occurs in children, in young women, without so much as destroying the hymen. 2. It is rarely if ever seen in cases of complete laceration of the perineum.

II. The vagina may have both an active and a passive action in the mechanism of descent. If the band of levator ani muscles which surrounds its tube in the lower third is lacerated, and its lower portion is still held by the rectum, the muscles surrounding it act with a powerful traction to bring down the posterior wall of the rectum; this traction, with traction of a like nature on the part of the bladder causes a prolapse of the vagina alone if confined to the lower portion, but when it involves the upper portion there is dragging of the neck of the uterus, which if the uterine supports are not lax, results in the great hypertrophy and lengthening of the neck which simulates complete procidentia. If the uterine ligaments are relaxed the uterus will follow sooner or later. 2. The softening and relaxing of the connective tissue during pregnancy make the detachment of the utero- and vagino-vesical attachments an easy matter, rendering and predisposing to prolapse. 3. The uterus can press down the vagina before it, making the vagina a passive agent in cases of rapid labor when the os is not dilated and the uterus descends towards the vulva with expulsive force of the third stage; also when it is heavy from lack of involution, as when the patient gets up too soon after confinement, or when subinvolution does not take place. 4. The vagina affords support to the uterus by its attachments to its neck; but it is a question whether it acts as a supporting column in the mechanical sense expressed by some writers, and whether the angle it forms with the uterus has a supporting value. Clinical experience shows many cases in which the walls of the vagina bulge and are prolapsed, in which the uterus retains its position, and also many cases, notably cases of congenital retro-displacements, in which the uterus remains at its normal plane.

III. The action of the ligaments is more passive than active. They are naturally lax owing to the necessity of uterine movements and uterine growth in pregnancy. If traction occurs from below, and the ligaments are lax, descent of the uterus is more facile. 2. The importance of the utero-sacral ligaments is exaggerated by most writers. 3. The appearance of the ligaments in cases of prolapse does not show their action; the stretching, breaking, and elongating is the result of the displacement, not the cause. In this respect experiments on the cadaver may be trusted for displacements of the uterus on the normal plane, but not in descent.

IV. The greatest factor to be considered in uterine displacements, and the least understood, is the intra-abdominal pressure. In the normal state there is such an adjustment of this that the uterus is easily maintained in position with little aid from ligaments, vagina, or perineum, in spite of the weight of abdominal viscera or the great and constantly recurring force of expulsive effort. When this equation is disturbed descent becomes easy. The maintainence of the uterus in its normal position is more a matter of physicodynamics than is generally supposed.

V. Owing to laxity of tissues, inherited or the result of disease or subinvolution, there may be a greater predisposition to procidentia uteri. The loss of fat has nothing to do with it, cases occurring very frequently in women with great accumulations of abdominal and other fat. The shape and inclination of the pelvis may also favor this condition Some writers think that too much is attributed to the effects of pregnancy as an etiological factor. Owing to its relaxing effects on all the ligaments and connective tissues, the heavy uterus of subinvolution, and insufficient care, it can, in the author's opinion, be held responsible for ninety per cent. of the cases.

The paper, which is illustrated with many cuts, most of them taken from the standard works on the subject, will be continued in the next issue of the journal.

Dr. W. L. Burrage discusses

**The Electrical Treatment of Fibroid Tumors of the Uterus,**

giving the results of three years' use of this agent. During this time he has seen in hospital and private practice ninety-eight cases of fibroid tumor of the uterus. Forty-four of these were treated with electricity and received at least six treatments each. As the result of this experience he gives the following:

1. Hysterectomy is contra-indicated in a majority of cases of fibroids because of the high rate of mortality, and because it unsexes the patient—the latter, an important consideration in younger women.

2. Intra-uterine galvanism is most advisable.

3. We must not look for a permanent reduction in the size of the tumor.

4. Galvanism—vaginal, intra-uterine, or by puncture—does not cause abscesses or adhesions.

5. Galvanism is of no use as a means of diagnosing the presence of pus.

6. Treatment by electricity after the Apostoli method is absolutely safe.

8. Every case of fibroid tumor of the uterus should be under competent medical observa-

tion, because of the danger of malignant degeneration, kidney disease from pressure on the ureters, complications during pregnancy, and the liability of the occurrence of pain and hemorrhage, and functional nervous disorders, especially during a delayed and protracted menopause.

The author includes in his paper a table of the cases treated showing the result of treatment, the length of time under treatment and the number of applications of electricity.

Dr. C. S. Hoffman describes

**A Peculiar Monstrosity.**

The abnormalities of the child, beginning from above down, consisted, 1st, in its being hydrocephalic. 2nd. The left external ear was very rudimentary, while the right external ear was normal. 3d. The left eye was very small and the opening in the orbicular muscle was only about one-third that of the right eye, which appeared normal. 4th. Both arms termininated at the lower end of the humerus, the radius and ulna being absent; but where these two bones should join the humerus, forming the elbow joint, is joined an imperfect hand having only three fingers on each hand, these fingers resembling most the little, ring and fore fingers. 5th. The child is a bilateral hermaphrodite, having a testicle upon each side in closed sac. The penis is very rudimentary and looks much like an enlarged clitoris; just back of it is an opening as large as a small crow's quill, into which a probe can be passed one-third of an inch. 6th. The anus is imperforate, the continuity of the skin being unbroken. 7th. There is talipes calcaneus of the left foot. In other respects the child was well developed. The child was born dead, but the mother said she felt it alive shortly before birth. There is no reason for the arrested development of the child.

Dr. Hannah T. Croasdale, reports a case of

**Two Separate And Distinct Uteri,**

which were centrally situated and not connected. The patient, æt. 63 years and the mother of three children, was admitted to the Woman's Hospital, in Philadelphia, for treatment of an abdominal tumor. Twenty years before she had noticed some enlargement of the abdomen, and in five years it had reached, she thought, its present size. No discomfort was felt (except from the size) until recently, when she experienced pain and pressure symptoms, and the bladder and rectum became very irritable. The menopause occurred at 50, and at this time the woman was confined to bed for several weeks; but there was no special reason for this, or she forgot just why she was in bed for that length of time. At the section for the removal of the tumor, a small, nodular mass attached to the lower part of the tumor, having the size and shape of the uterus, and being furnished with what seemed to be the uterine appendages, was drawn out of the lower end of the wound, and was found to be attached by a small cord-like pedicle to the pelvic brim a little below the crest of the left ilium. Another body, to all appearances a uterus with its appendages, was found crowded down into Douglas' pouch by the tumor. The patient died of sepsis on the ninth day. At the autopsy a uterus and its appendages were found in the proper position. The author thinks it a case of two separate and distinct uteri. The second uterus had developed from the cervix the fibroma and measured from the internal os to the fundus one and one-quarter inches. On cutting it open the arbor vitæ arrangement of the mucous membrane was shown quite distinctly. The os uterinum on the left side admits of the passage of a small probe, which passes a short distance along the Fallopian tube. On the opposite side the opening would not admit the probe. There are two small ovaries. In the cervical canal, just below the os internum, is a small calcareous deposit.

The same author also reports a calcified corpus luteum.

Dr. W. P. Carr contributes a paper on

**Chronic Salpingitis,**

reporting five cases. The author does not advocate the removal of the appendages for every case of catarrhal or chronic salpingitis. He is certain, however, that adherent tubes or tubes containing small quantities of pus, may be the cause of suffering sufficient to wreck a woman's health without giving rise to any well-marked physical signs of pelvic disease. And when the pain is great, when the general health is being undermined, when other treatment fails, he thinks removal of the appendages becomes not only justifiable, but a procedure that it is the physician's duty to recommend. He believes, too, that in all obstinate and unyielding cases the tubes will be found to be solid cords in some part of their extent, and the woman will in consequence be always sterile, so that all arguments based upon the sterilization and mutilation of women are inapplicable to these cases.

The remaining papers in this issue are:

"Acute Non-Puerperal Metritis, with report of a case," by Frank H. Murdock, M. D.

"The Complications of the Puerperal State," by Llewellyn Eliot, A. M., M. D.

"The Causes of Shoulder Presentations, With a Report of a Case," by Sigmar Stark, M. D.

"Three Illustrative Cases of Abdominal Section," by Aug. Schachner, M. D., Ph. G.

---

ATLANTA MEDICAL AND SURGICAL JOURNAL for March. Dr. A. Joffray, of Paris, writes of the

**Nature and Symptoms of Exophthalmic Goitre,**

and thinks that it is due more to some functional vice, or to some alterations in the thyroid gland, than that it is a pure neurosis.

The four principal signs usually given are the exophthalmia, tumor of the thyroid, rapid pulse, tremulousness of the extended hands. The right lobe is generally found larger than the left, and on applying the hands to the organ pulsation and also a characteristic thrill are felt.

Contrary to the common teaching, the author says, there is no such thing as a purely vascular enlargement of the thyroid; but we can always find, by careful examination, hard nodules of circumscribed inflammation or of colloid infiltration, showing an organic change, and this is the case in those which appear to be of only a few hours' duration as well as in those of more gradual appearance. In some cases even, when the other symptoms were marked, inspection, or even very careful palpation failed to disclose any enlargement in a thyroid which at a subsequent autopsy showed very great hypertrophy.

At menstrual periods a goitre is apt to enlarge, under the influence of various emotions it may do so, and may diminish without relief of symptoms; or the symptoms may lessen or disappear without apparent lessening of the goitre.

The heart usually beats strongly, slowly, and regularly; but in a longstanding or cachectic case, without organic heart affection, there may be irregularity or intermission of the beat. In some cases organic change occurs in the heart apparently as a result, at other times it seems a mere coincidence.

The carotids and other cervical and cephalic vessels often dilate and throb greatly, while, in contrast, other arteries may be almost imperceptible.

Exophthalmia is common but not constant, and when present is usually unequal but bilateral, the degree bearing no apparent relation to the development of the disease, and there is also no relation between the eye most affected and the greater lobe of the goitre.

In spite of displacement the author says there is often no visual disturbance, but the various muscles around the orbit are interfered with, and to this is due the sign of De Graefe (the failure of the eye and upper lid to move in unison) and that of Stellwag (the enlargement of the palpebral fissure, and the failure to completely close it, although the sensation of having done so exists.)

This symptom of Stellwag appears without perceptible exophthalmia and may be almost wanting in pronounced cases.

Paralysis of the muscles of the forehead and face occurs and is apt to be symmetrical, and a vibratory motion of the eyelids, simular to that seen in hysteria, the author calls "batting," and states that although all of these are important phenomena they have not received due attention.

Dr. N. F. Howard "Gives a new Treatment for Burns." A solution of one pound Epsom salts in two quarts of water, in which the burned part is to be immersed if possible. This treatment gave prompt relief in a couple of cases, where the ordinary treatment of linseed oil and lime wates had failed.

After relief of pain the usual dressing was applied, and healing rapidly took place.

Dr. W. P. Northrup read before the New York Academy a paper on

**Scurvy in Children,**

and in the discussion it appeared that members had observed seventy-two cases, and since attention has been attracted to the subect lately only, it must be of rather frequent occurrence.

The author mentioned a few individual cases: The first was a foundling brought to the hospital with swollen leg and knee, and developed swollen and spongy gums, and hemorrhages into the skin and bowels. At the autopsy pleuro-pneumonia, and entensive femoral and tibial subperiosteal hemorrhages were found.

Another child, the parents being people in good circumstances, had been fed on prepared baby food for a year, when much the same condition developed. Rheumatic treatment failing, the child was fed on milk, beef-juice, potatoes and orange juice, and promptly began to improve.

Much the same features prevailed in other cases; one had been fed by a wetnurse, who at the same time nursed her own child; but most of the infants had been fed on patent baby food or condensed milk, one on beef juice for three months.

Various diagnosis were given by the physicians who first saw the cases—hip disease, spine disease, infantile paralysis, etc., and in one case cited the spinal distortion seemed quite evident, but turned out later to be due to contractures of the muscles from effusions into their sheaths and to periostitis.

---

BULLETIN DE THERAPEUTICS

Dr. Darrier describes a treatment of

**Epithelioma of the Face**

with which he claims success.

After removal of scales and crusts, the surface is anæsthetized with ten per cent. solution of cocaine. The affected surface is then wet with methyl blue, one gramme, alcohol and glycerine each five grammes.

To all parts stained blue, a light application of a solution of chromic acid, one to five, is made causing a purple color. The blue is now again applied and the surrounding parts carefully washed. To prevent crusts starch poultices or sublimate compresses are used. These applications are made four or five times, at intervals of two or three days; after which the blue is used alone until the skin no longer absorbs the color. For each square centimetre will be required about one month of treatment. Brilliant immediate results appear, and they seem lasting.

---

**Chloroform Narcosis.**

Resuscitation in chloroform narcosis has been accomplished by a new method devised by Maas, one of Koening's assistants of Goettingen. In the first case, the ordinary means of resuscitation had been tried for an hour without effect; respiration and pulse has entirely ceased. Maas then made rapid rythmical compressions, about one hundred and twenty per minute, of the cardiac region, whereupon the hearts' action gradually increased and the patient recovered. A second severe case responded with the same result to the treatment. Mass ascribes the effect of the cardiac compressions to the driving of the blood into larger arteries.—*Chicago Medical Recorder.*

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## MEDICINE.

### Thymol in Toothache.

Dr. Hartmann (*Deutsche Med. Wochenschrift*) has employed thymol in toothache from hollow teeth, in place of arsenious acid. He fills the cavity of the tooth with a tuft of cotton on which a few crumbs of thymol have been sprinkled. It does not irritate the mucous membrane of the mouth much, and it is easily removed by rinsing the mouth with water. If a rapid action is desired let the patient rinse the mouth often, with warm water, in order to facilitate the solution of the drug. It never increases the pain at first, as arsenic does, and is not poisonous.—*Lancet-Clinic.*

### Hydrogen Peroxide a Hemostatic.

Brewer (*N. Y. Med. Jour.*) calls attention to this property of the drug. He has used it to arrest hemorrhage after operations upon the nose and throat and found it promptly effectual where other methods, including powerful chemical stiyptcs and plugging had failed. The ordinary fifteen volume solution is to be applied either on a cotton swab or sprayed directly upon the bleeding surface.

### The Treatment of Lupus by Salicylic Colloid.

E. Mansel Sympson, M. D., says for nearly five years I have used salicylic colloid in the treatment of lupus vulgaris affecting the skin.

The formula is as follows:

℞ Acidi Salicylici ..... 3j.
Extracti Cannabis Indicæ ..... gr. x.
Collodii Flexilis ad ..... 3j.
Fiat pigmentum.

It seemed so safe and so easily applied by unskilled persons, it caused so little pain comparatively, and the chances of its destroying the affected area of skin were so great, that I chose this form of applying salicylic acid in preference to any other, such as the plaister-mull or the salicylic plaister.

Much in the same way in which it acts on warts and corns (in which however the horny layer of the epidermis is equally predominant with the elongated and enlarged papillæ) it acts on lupus. Under its influence ulcerating patches dry up, tubercules disappear, and the resulting cutaneous tissue is much more flexible and natural in appearance than is generally the case in lupus.

One patient of mine has used it now for quite four years, and can take any situation without difficulty, the salicylic colloid keeping the disease in check. Indeed, this virtue of checking the return or advance of lupus is one of the chief reasons why I have brought this subject before the readers of the *Practitioner*. Nothing that I know of will *cure* lupus; often cases amend for a time and then progress no further. After scraping, for instance, and touching up with the cautery, great improvement may immediately ensue; but it is quite probable that there will be another outbreak at no distant period.

With salicylic colloid, however, the disease can be diminished and held back with ease. The constant need to repeat the application is of very small account compared with the dread of an operation. In one case I scraped thoroughly one side of the face in a well-marked subject of lupus, which Dr. Harrison had kindly handed over to me, painted the other with the colloid. Unmistakably the side painted got better quicker than the side scraped. Where the area to be painted is large, a little can be done every day, ensuring that each part of the diseased surface shall be painted about twice a week.

Although it scarcely comes within my heading, I may mention that for lupus of the mucous membrames I use the red oxide of mercury ointment.—*Practitioner.*

### Vinegar as a Remedy Against Vomiting After Chloroform.

Immediately after having performed the operation and placed the patient in bed, he (Warholm, in *Sattellite*) applies a handkerchief moistened with vinegar in front of the nose, letting it remain there until the patient returns to consciousness, or longer if it agrees with him. Of thirty cases experimented upon by the author, the majority were benefitted. In most of them the effect was absolute. In two cases the remedy did not succeed; one of these was an alcoholist. The patient should have a small phial, filled with vinegar, standing at his bedside, to smell as the demand arises.—*Southern Clinic.*

### The Treatment of Tuberculous Pleurisy.

Dr. William Osler states that the indications are twofold: First, to limit and control the exudate and to promote its absorption. In the early stage it is sufficient to allay the pain, if severe, with opium; to reduce the fever, if high, by sponging, and to keep the bowels freely opened. It is doubtful whether the salicylates deserve the confidence which many claim. While fluid remains in the chest it is for the good reason that it cannot get out, owing to blocking of the lymph paths. Absorption from the pleura goes on, chiefly if not entirely, from the costal layer. Good results are seen from putting the patient on a dry diet, and giving brisk saline cathartics. Diuretin, when it acts, is useful in the same way. If at the end of ten days the exudate persists, and is at the level of the fourth rib in the erect posture, aspiration is advisable, and this may be repeated in a few days if the fluid reaccumulates. There are

no greater risks in the tuberculous than in the simple sero-fibrinous cases, and it is very important to relieve the lung early of the compression to which it is subjected by any large quantity of fluid. The risk of the compressed lung becoming the seat of tuberculosis is not very great; more serious is the danger lest it should become bound down by such firm adhesions that it cannot expand. Gentle counter-irritation of the skin is probably beneficial in these later stages, stimulating the lymphatics of the costal pleura. In chronic sero-fibrinous effusion with thickening of the membranes, the fluid reaccumulates rapidly, and aspiration may have to be performed many times, and pulmonary gymnastics should be practiced. If the exudate be purulent the case should be transferred to the surgeon for thorough drainage. The second indication is to improve in every way possible the general nutrition of the patient, so as to favor conditions promoting the healing of the tuberculous process. No doubt, as in pulmonary and peritoneal infection, many instances of tuberculosis of the pleura recover, and leave no more damage than that associated with slight thickening of the membrane. A life in the open air, regular habits and exercise, a nutritious diet, and the use of the remedies which promote in every way digestion and the assimilation of food, should be advised.—*Transactions of the Massachusetts Medical Society*, 1893.

### An Easy Method of Keeping Warm.

I should like to call attention to an easy method of warming one's self when other and more common means are not available. It is a method that I suppose is well enough known to the profession, but probably not often used. I allude to warming the body by merely taking deep inspirations.

On the very cold afternoon of this winter, though walking briskly along, I was uncomfortably cold; feet and hands were very cold, and my ears so chilled as frequently to require the application of my heavily gloved hands. In addition, the whole surface of the skin was unpleasantly chilled; "creeps" ever and anon running up and down my spinal column and radiating thence over the body and extremities; in short, a condition that every reader of this little article has doubtless many a time experienced. I then began taking an exercise often employed before with benefit; deep forced inspirations, holding the air as long as possible before expulsion. After a few inhalations the surface of my body grew warmer, and a general sense of comfort pervaded me. Continuing, the next part to feel the effects of the effort was my previously frigid ears; they grew agreeably warm, and within the time required to walk three blocks, at the previous space, hands and feet partook of the general warmth and I felt as comfortable as if the same length of time had been passed by a glowing fire.

The happy results obtained from this simple method are probably owing to several causes:

The cold of course chills the surface of the body and contracts the superficial blood-vessels, usually affecting first hands, feet and ears, and afterwards the general body surface. Contraction of the blood-vessels results both in less blood to the part and in stagnation of the current, thus rendering the tissues still less able to resist the cold. Deep forced inspirations not only stimulate the blood-current by direct muscular exertion, but also by compressing and expanding the lungs, the flow of blood is greatly hastened through this organ, and on account of the increased amount of oxygen inhaled, this abundant supply of blood is thoroughly oxygenated, tissue metabolism is increased and more heat necessarily produced.

Many times unavoidable exposure as in riding, driving, standing and the like, for a longer or shorter time in the cold, has been the cause of severe and even fatal congestive troubles, such as pleurisies and pneumonias, and a means of quickly stimulating the flagging peripheral circulation which a person has always with him, and which can be employed without moving a step, is one that ought not be neglected or forgotten.—Ernest B. Sangree, M. D., in *American Therapist*.

### Treatment of Acute Urethritis.

In the first or increasing stage of an acute urethritis, whether specific or otherwise among the many plans of treatment, there is the well known one of increasing the amount of urine voided and conjointly with this rendering it alkaline. During this stage we have marked urethral symptoms, as ardor urinæ, chordee, etc. The following formula is much used in the service of Prof. Neilson, and I can say from a somewhat extended clinical experience with it, that it almost always accomplishes the object aimed at, namely; affecting the urine so that the urethral symptoms of the early stage of an acute urethritis are much modified:

℞
Potassii acetatis.....3iij
Potassii bromidi.....3iss.
Acidi borici.....3ij 6ij.
Tr. belladonnae.....3ss.
Sig. Potassii citratis, qs. ad.....3viii.

M. S. A teaspoonful in a goblet of water three or four times a day.

In giving your directions to the patient it is important that he understands he is to take a liberal quantity of water with his medicine and I think the remedy is better taken about two hours after meals.

The potash salts can be presented in such doses as the physician thinks best meets the immediate case. The boracic acid renders the urine to a degree antiseptic and I have never seen it produce any depression in the above dose—ten grains. The dose of belladonna seems to have a soothing influence on the mucous membrane. The formula given above is not original in any way and is only given as a combination, very effective in a large clinical service.—Dr. Lindsay, in *Philadelphia Polyclinic*.

### Some Practical Points in Infant Feeding.

Louis Fisher, M. D., in the *Amer. Medico-Surg. Bull.*, says: First, always try to feed the child with "its own" mother's milk. A child may receive both breasts alternately at one meal if the appetite warrants it. Never have a baby fed by the milk of its mother if the latter suffer with general debility or tuberculosis. Extremely nervous mothers should not nurse their babies.

Syphilitic babies (hereditary) can only be nursed by their own mothers, owing to the risk of infecting the wet-nurse. Very frequently the life of the child is dependent on its being nursed by its mother in syphilis.

(*a*) The return of menstruation is no contra-indication to the continuation of nursing.

(*b*) The moment a woman is pregnant nursing should be stopped.

(*c*) Children should not be nursed at night unless for some special reason.

(*d*) Weaning should take place gradually and only in the eighth to the tenth month.

(*e*) It is understood that weaning should not be commenced during the hot summer weather.

The main factor in determining the time of weaning is "weighing." Children must be weaned when, although in perfect good health, they remain below normal weight.

(*f*) Prolonged nursing (useless) will induce rhachitis (rickets).

2.—If, for various reasons, a child cannot be nursed by its mother, we then resort to the wet-nurse.

(*a*) She must be carefully examined as to her physical condition; tuberculosis, all chronic disorders and diseases would prevent proper nursing. Hereditary nervous troubles, epilepsy, syphilis, would exclude nursing.

Milk requires microscopical examination to determine amount of fat, the condition of the emulsion, etc.

(*b*) It is a good point to try to procure a wet-nurse suckling a child about as old as the one we wish her to nurse, although it is quite common to find nurses who have older children than the one they wish to nurse and to find the latter doing well.

(*c*) The proof of the usefulness of the wet-nurse is the condition of the baby after some time. If the child thrives it will increase in weight. Hence scales must be frequently used.

3.—Artificial substitutes for breast milk:

(*a*) Never give any food preparation containing *starch* during the first three months.

*Cows' milk.*—There is a great difference between human and cow's milk—hence we must dilute accordingly.

Dilute—in order to make it as near mother's milk as possible—by adding substances which will make the milk easily digestible and not curdling.

Alkalis and acids should not be used, or only to correct pathological conditions. Add farinaceous substances:

(*a*) Oatmeal gruel were constipation exists.

(*b*) Barley gruel where tendency to diarrhœa exists.

It is advisable to use shells of the cereals, as they contain a certain quantity of albuminoids.

Sugar is added by using sacch. lactis; salt is added by using ordinary table salt.

Certain dangers of feeding by cows's milk and their avoidance:

Possible transmission of tuberculosis, owning to which fact it is advisable to feed from several cows and not from a single cow—contrary to the general opinion.

The milk must be boiled, and thoroughly so, in order to destroy one of the most frequent contaminations, namely, micro-organisms.

Boiling methods have been improved upon by introduction of sterilization by Prof. Soxhlet, and since then by partial sterilization called pasteurization.

---

### Treatment of Tuberculosis of Lungs.

Dr. Carasso reports thirty-nine cases treated with great success as follows: Continuous inhalations of peppermint-oil, internal administration of an alcoholic solution of creasote, glycerine, and chloroform and one per cent of peppermint-oil. Bacilli disappeared in from two weeks to two months. The bodily weight increased, the appetite improved, the cough, sweating and expectoration disappeared and the lungs apparently healed—*Gazetta degli Ospitali.*

---

### Rheumatism.

Ointment of salicylic acid, turpentine and lanolin speedily relieved the pain of articular rheumatism, and reduced temperature to normal before the fifth day. No unpleasant effects, such as often follow large internal doses of the salicyl compounds. It is also valuable in subacute rheumatism and lumbago.—Bourget, in *Therapeutische Monatschifte.*

---

### Oxalic Acid as an Emmenagogue.

Parlet strongly recommends oxalic acid for this purpose. He prescribes:

℞ Oxalic acid.....gr. xxx.
Infus. tea.....℥vi.
Syrup of orange peel.....℥vi.
M. S. ℥ss every hour.

It is especially at the expected time of the appearance of the menses that this is indicated. Under these conditions it surpasses all the other emmenagogues of the most repute. —*Times* and *Register.*

---

## SURGERY.

### The Intravenous Injection of Saline Fluid.

In a minor editorial article the *Lancet* for January 13th says:

There can be little doubt that the injection of salt solution into the veins constitute a valuable addition to our therapeutic measures in certain otherwise hopeless cases. We re-

fer more especially to cases of severe accidental or unavoidable hemorrhage, to severe cases of post partum hemorrhage, as well as to cases of extra uterine pregnancy where there has been rupture of the sac with profuse intraperitoneal hemorrhage. It would seem that the injection is also indicated in some cases of severe operation where a large quantity of blood has been lost, but less than is needed to prove immediately fatal. In a certain proportion of such cases, although the patient is not pulseless at the end of the operation, death occurs before many hours have elapsed, apparently from secondary syncope. In some cases of this kind, at all events, it appears probable that the injection of salt solution may avert an unfavorable termination. It is certainly a great step in advance to have it established that the injection of actual blood is unnecessary; for so long as blood was thought to be required the practical difficulties surrounding the procedure were so great that it has but rarely been employed; and it is, in the light of our present knowledge, as certain as anything can well be that many lives have been lost solely for the want of some ready means of restoring the volume of the circulating fluid. It is evidently of great importance that the method should be a simple one, and especially that it should not involve the possession of some more or less complex apparatus which the ordinary practitioner could not be expected to have on hand. As regards the fluid to be used, the simplest of all—plain water—will do, since successful cases are reported in which water has been injected; but it is certainly preferable to use a solution of common salt, the proper strength being a teaspoonful of the latter to a pint of water. Here again, while it is no doubt desirable, if circumstances permit, that the solution should be sterilized, it is abundantly clear that it is by no means absolutely essential. A patient should not be allowed to die from loss of blood, where it is practically certain if let alone she would do so, merely on account of an extremely remote risk of septic poisoning from the water in the kitchen kettle and the salt in the table salt cellar. Then as to the quantity of fluid to be injected. This should depend upon the amount of blood that has been lost, but this often cannot be accurately estimated. It is important to note, however, that a few ounces are of little or no use. In cases really requiring this treatment it is a question of injecting pints. From a minimum of two pints in the less severe cases to a maximum of six pints in the worst cases in the amount of salt solution to be used. This should be continued till the pulse can be felt at the wrist. Opinions differ as to the rate at which the fluid should be injected; some consider that a pint in four minutes is not too fast, while others think that the rate of injection should be a third of this or less. Probably the actual state of depletion of the circulation causes the rate at which the injection may be safely made to vary in different cases. The temperature of the fluid used should be about the same as that of the body. The actual apparatus required consists only of a cannula and a few feet of India rubber tubing connected with a vessel to hold the salt solution. The form of the vessel is immaterial; indeed, the tubing, converted into a siphon, may be made to convey the fluid from an ordinary jug: Now that the whole procedure has been so much simplified, we may expect to hear of it being more frequently resorted to in the coming year. Certainly no patient should be allowed to die from hemorrhage without an attempt being made to save her by means of the intravenous injection of salt solution.

## ARMY AND NAVY.

U. S. ARMY FROM MARCH 17, 1894, TO MARCH 31, 1894.

Fessenden, C. S. D., Surgeon; detailed as chairman Board for physical examination of Asst. Surgeon L. E. Cofer, March 6, 1894.

Purviance, George, Surgeon; detailed as chairman Board to inspect Reedy Island Quarantine, February 20, 1894; to report at Bureau for temporary duty, March 2, 1894.

Hutton, W. H. H., Surgeon; detailed chairman Board for physical examination of Inspector of Hulls, March 9, 1894.

Gassaway, J. M., Surgeon; detailed as Recorder Board for physical examination of Asst. Surgeon L. E. Cofer, March 6, 1894.

Godfrey, John, Surgeon; detailed as chairman Board for physical examination candidates, Revenue Marine Service, March 6, 1894.

Irwin, Fairfax, Surgeon; to proceed to Paris, France, for special duty, February 24, 1894.

Mead, F. W., Surgeon; detailed as chairman Board for physical axamination of candidates, Revenue Marine Service, March 10, 1894.

Carter, H. R., Surgeon; to report at Bureau for special duty, March 14, 1894.

Banks, C. E., Passed Asst. Surgeon; to proceed to Portsmouth, N. H., as inspector, March 12, 1894.

Kalloch, P. C., Passed Asst. Surgeon; granted leave of absence for thirty days, March 12, 1894.

Glennan, A. H., Passed Asst. Surgeon; detailed as member Board to inspect Reedy Island Quarantine, February 20, 1894.

Wasden, Eugene, Passed Asst. Surgeon; granted leave of absence for sixteen days, March 3, 1894.

Kingyoun, J. J., Passed Asst. Surgeon; to report to Chairman Committee on ventilation and acoustics House of Representatives for special duty, February 21, 1894.

Woodward, R. M., Passed Asst. Surgeon; to report at Bureau for special duty, March 14, 1894.

Guitevas, G. M., Passed Asst. Surgeon; granted leave of absence for twenty days, February 19, 1894

Stimpson, W. G, Asst. Surgeon; granted leave of absence for twenty-five days, March 5, 1894; detailed as Recorder Board for physical examination of inspector of Hulls, March 9, 1894.

Houghton, E. R., Asst. Surgeon; ordered to examination for promotion, March 3, 1894.

Rosenau, M. J., Asst. Surgeon; ordered to examination for promotion, March 6, 1894.

Cofer, L. E.. Asst. Surgeon; to report to Board for physical examination, March 6, 1894; placed on "waiting orders," March 15, 1894.

Gardner, C. H., Asst. Surgeon; detailed as Recorder Board for physical examination of candidates, Revenue Marine Service, March 10, 1894.

Steward, W. J. S., Asst. Surgeon; detailed as Recorder Board for physical examination candidates, Revenue Marine Service, March 10, 1894.

## NEWS AND MISCELLANY.

### American Medical Association.

*San Francisco Meetings, June* 5-8, 1894.

SECTION ON SURGERY AND ANATOMY.

John B. Roberts, M. D., Philadelphia, Pa., Chairman. Lloyd W. McRae, M. D., Atlanta, Georgia, Secretary.

It is proposed to devote a portion of the time of this section to the systematic consideration of a few selected subjects, upon which papers, each not occupying more than ten minutes will be read. It is hoped that speakers discussing these papers will confine their remarks to brief addresses of five minutes' length. The topics and papers to be presented are as follows:

I. MALIGNANT GROWTH.—The Pathology of Malignant Growths: E. Laplace., Philadelphia, Pa. A Critique of the Sporozoan Theory of Malignant Neoplasms from a Micro-technical Standpoint: A. P. Ohlmacher, Chicago, Ills. Clinical Recognition of Malignancy in Tumors: C. A. Wheaton, St. Paul, Minn.; Henry W. Coe, Portland, Oregon. The Necessity of Early Surgical Interference in Malignant Tumors: R. A McLean, San Francisco, Cal. The Value of Caustics in Malignant Growths: John Parmenter, Buffalo, New York. The Radical Cure of Malignant Tumors by Operation: J. H. Wythe, Oakland, Cal. The Value of Inoculations with Septic or Toxic Agents in the Treatment of Malignant Neoplasms: John A. Wyeth, New York, N. Y.

II. TUBERCULAR DISEASE OF JOINTS.—Early Symptoms and Diagnosis of Tubercular Joint Disease: Emmet Rixford, San Francisco, Cal.; A. B. Judson, New York, N. Y. Conservative Treatment of Tubercular Joints: R. H. Sayre, New York, N. Y.; Harry M. Sherman, San Francisco, Cal; James E. Thompson, Galveston, Texas. Operative Treatment of Tubercular Joints: Robert W. Lovett, Boston, Mass. Treatment of Tubercular Joints by Injections of Iodoform: N. Senn, Chicago. Treatment of Tubercular Joints by Injections of Corrosive Sublimate: R. H. Plummer, San. Francisco, Cal.

III. HERNIA.—The Causation and Prevention of Hernia: James T. Jelks, Hot Springs, Arkansas: C. M. Richter, San Francisco, Cal. The Management of Reducible Hernia: Emory Lanphear, Kansas City, Mo.; C. M. Fenn, San Diego, Cal. The Treatment of Irreducible Hernia: James B. Eagleson, Seattle, Washington. The Treatment of Strangulated Hernia: Joseph Ransohoff, Cincinnati, Ohio. The Radical Cure of Hernia: W. E. S. Davis, Birmingham, Ala.; H. O. Marcy, Boston, Mass.

IV. HEMORRHOIDS, FISTULE AND FISSURE.—The Pathology and Symptamology of Hemorrhoids, Anal Fistule and Anal Fissure: J. M. Matthews, Louisville, Ky.; David Powell, Marysville, Cal. Treatment of Hemmorrhoids: H. M. Bishop, Los. Angelos, Cal.; Charles B. Kelsey, New York, N. Y. Treatment of Anal Fistule: J. McF. Gaston, Atlanta, Ga.; G. B. Somers, San Francisco, Cal. Treatment of Anal Fissue: Thomas, W. Huntington, Sacramento, Cal.; Lewis H. Adler, Jr., Philadelphia, Pa.

V. FRACTURES.—Treatment of Fractures of the Lower End of the Humerus: Oscar H. Allis, Philadelphia, Pa. Treatment of Fractures of the Lower End of the Radius: P. T. Connor, Cincinnati, Ohio: C. L. Bower, Philadelphia, Pa. Treatment of Fractures of the Neck of the Femur: Bedford Brown, Alexandria, Virginia. Treatment of Gunshot Fractures: George A. Goodfellow, Tucson, Arizona. Treatment of Fractures of the Shaft of the Femur: Llewellyn Eliot, Washington, D. C. Treatment of Open or Compound Fractures: H. H. Mudd, St. Louis, Mo.; John B. Hamilton, Chicago, Ills.

VI. Obstruction to Urination in the Male.—Effects of Obstruction in Urination Upon the Bladder and Kidneys: J. William White, Philadelpdia, Pa. Diagnosis and Treatment of Enlargement of the Prostate Gland: Hunter McGuire, Richmond Va.; Wm. T. Belfield, Chicago, Ills. Symptoms and Treatment of Stone in the Bladder; William T. Briggs, Nashville, Tenn. Symptoms and Treatment of Tumors of the Bladder: John B. Deaver, Philadelphia, Pa.; C. F. Buckley, San Francisco, Cal. Treatment of Stricture of the Urethra: J. Rosenstirn, San Francisco, Cal.

Members who have specimens or patients to exhibit bearing on these topics, or who wish to make remarks in the discussion of them are cordially invited to be present during the meetings of the Section. The titles of other papers to be presented to the Section will be published when the programme of the Meeting of the Association is issued by the Committee of Arrangements.

JOHN B. ROBERTS,
1627 Walnut street, Philadelphia, Pa.
Chairman Section on Surgery and Anatomy.

### American Surgical Association—Session of 1894.

SPECIAL SUBJECTS FOR DISCUSSION.

*I.* "*Surgical Treatment of Empyema.*"

BY JOHN ASHURST, JR., M. D.

SUMMARY.

1. No operation is justifiable unless the presence of pus is certain; unless thorough treatment by medicinal agents, blisters, etc.,

has failed; or unless the symptoms, dyspnœa, etc., are so urgent as to demand immediate relief.

2. The first operation should consist of simple aspiration, with antiseptic precautions.

3. When the fluid has partially reaccumulated, as it almost certainly will do if purulent, incision and drainage should be practiced.

4. Drainage is best effected by making two openings, one at the lowest point, and carrying a large drainage-tube through the cavity from one opening to the other.

5. Drainage should be supplemented by washing out the cavity with mild antiseptic fluids; when the lung has expanded and the discharge has nearly ceased, the tube should be shortened, the upper opening being allowed to heal, and the tube then being gradually withdrawn through the lower opening.

6. When the lung is so bound down by adhesions that it cannot expand, resection of two or more ribs should be practiced (Estlander's operation, so-called), in order to allow collapse of the chest wall and to promote healing by bringing the costal and visceral layers of the pleura into contact.

7. The more extensive operations of Schede and Tillmans, while probably justifiable in exceptional cases, are not to be recommended for general employment.

The discussion of the paper will be opened by Drs. N. P. Dandridge, C. B. Dancrede, T. F. Prewitt, and De F. Willard.

---

*II.* "*Methods of Teaching Surgery.*"

BY J. S. BILLINGS, M. D.

SUMNARY.

Two classes of students. 1. Undergraduates. 2. Those wishing to make a special study of Surgery.

For the first class, work of teaching divided between Professors of Pathology, of Surgery, and of Clinical Surgery, and Demonstrators.

What shoud be the relations between these and the teachers of Gynecology, Orthopædic Surgery, Genito-Urinary Surgery, etc.?

Methods of teaching. 1. Didactic lectures. 2. Recitations. 3. Demonstrations by means of manikins, cadavers, operations on animals, etc. 4. Clinical lectures to large classes. 5. Practical clinical instruction to small classes.

How far should the didactic teaching be subordinated to clinical and demonstrative teaching?

Relations of hospitals to clinical teaching. Instruction in History and Literature of Surgery.

Provisions to be made for special students.

The discussion of the paper will be opened by Drs. J. C. Warren, N. Senn, W. W. Keen, E. M. Moore, W. T. Briggs, and Hunter McGuire. It is desired that the discussion of this paper should be participated in by the Fellows generally.

"*The Surgery of the Kidney.*"

BY L. M. TIFFANY, M. D.

SUMMARY.

1. Influence of disease of kidney on general surgery.
2. Nephritis.
3. Pyelonephritis.
4. Nephrolithiasis.
5. Nephrectomy, partial and complete.

The discussion of the paper will be opened by Drs. M. H. Richardson, H. H. Mudd, C. H. Mastin, and Ford Thompson.

---

*IV.* "*Methods of Controlling Hemorrhage in Amputation at the Shoulder,*" *as illustrated by three cases of amputation at the shoulder-joint and of the entire upper extremity.*

BY W. W. KEEN, M. D.

SUMMARY.

1. Amputation at the shoulder-joint with the use of Wyeth's pins.
2. Amputation at the shoulder-joint with preliminary ligation of the vessels in the interspace between the deltoid and the pectoral muscles.
3. Resection of the clavicle and securing the vessels, followed by amputation of the entire upper extremity, including the clavicle and scapula.

The discussion of the paper will be opened by Drs. Roswell Park, C. B. Porter, and J. William White.

---

V. PAPER BY HUNTER MCGUIRE, M. D.

---

VI. PAPER BY JOSEPH RANSOHOFF, M. D.

---

Fellows who desire to present volunteer papers are requested to send the titles of the papers to the address of the Business Committee, 1429 Walnut Street, Philadelphia, not later than April 18th, 1894.

---

The sessions of the Association will be held in the Lecture-room of the Medical Department of the Columbia College, 1325 H Street, N. W., Washington, D. C., on May 29th, 30th, 31st, and June 1st, from 10 A. M. to 1 P. M.

The sessions of the Congress will be held in Metzerott's Hall, corner of Twelfth and F Streets, N. W., in the afternoon from 2 to 5 o'clock.

The office of registration of the Congress will be at the Arlington Hotel. Registration of individual members of the constituent associations of the Congress is necessary to make them members of the Congress.

Dinner to the guests of the Congress at the Arlington Hotel, Wednesday, May 30th, 7 P. M.

Reception by the President of the Congress, Thursday evening, May 31st.

J. R. WIEST, M. D., *Secretary.*

## ORIGINAL ARTICLES.

### DIABETES MELLITUS, WITH REPORT OF TWO CASES.*

GEO. F. BATES, A. M., M. D.,† Hillsboro, N. D.

In entering upon a discussion of the above subject, I am aware that in all probability, I shall have nothing new to offer as regards either etiology, pathology or the treatment of the disease. However, in bringing out the history of two of my cases, I think the majority of physicians will find *symptoms* which will prove as new and interesting to them as they have to me.

I pass rapidly over the causes of this disease. Theoretically, it has been traced to derangements of various organs; in fact, there is hardly an important organ in the body which has not at some time or other been accused of being the seat of changes, which either directly or indirectly, have laid the foundation for the disease known as diabetes. It is a disease of whose very nature we are ignorant. Are not the great majority of autopsies from which our data are collected, held upon bodies of those who were in the shadow of death before their disease was recognized and treated?

Has the morbid anatomy of the liver, the medulla, the pancreas or the kidneys, ever been studied at the time when sugar first appeared in the urine? What physician, as a rule, ever sees these cases in their incipiency? Who shall say, therefore, which of all these morbid changes described to-day in our textbooks, are the causes and which the results of this disease? It appears from quite an extended research that most authorities concur in the opinion that derangement (either functional or organic) of one or all of the above mentioned organs is an important factor in the causation of diabetes —this *bete noir* of the profession. Much has been said in favor of each theory and nothing decisive in favor of any. So we are at liberty to go over the field and choose for ourselves which theory we will adopt.

I long ago chose to accept the theory of its nervous origin, and I have not done this from any extended pathological investigations, but from a careful observation of the effects of different drugs upon the disease itself. It is true that we often, yes usually, find functional and organic changes in some of the other organs, such as the liver, pancreas, lungs and kidneys, but all of these are easily explained as being *results* of deranged innervation, not *causes* of the disease in question. So in the treatment we are compelled usually to employ remedies directed to the relief of these conditions as *adjuvants* merely to the main line of treatment, which I claim to be the exhibition of nervous tonics or sedatives according to the indications in each particular case.

Pathologically considered, the disease presents no constant lesions. We find the liver sometimes enlarged and fatty, sometimes small and cirrhotic. The pancreas occasionally is fibroid and cirrhotic, sometimes fatty, and frequently perfectly nor-

*Read before North Dakota Med. Association, 1893.

†Late Professor of Materia Medica and Therapeutics, College of Physicians and Surgeons, Minneapolis, Minn.

mal. The nervous system, both sympathetic and cerebro-spinal, presents some lesion or other almost invariably; sometimes a tumor, sometimes a sclerosis, often cysts, and in some cases we find a well defined neuritis. The lungs and kidneys also present various changes, but nothing which may be said to have a causative relation to the disease.

A few words now in regard to the symptomatology of diabetes. As a rule, I think, the younger members of the profession are apt to be deceived by the usual picture of the disease as given in our standard medical works. It is described as a nutritive disorder, attended by an excretion of sugar in the urine, which is usually increased in quantity. They inform us that we are to look for something similar to the following: Intense thirst, accompanied by the excretion of immense quantities of saccharine urine, the amount of this urine bearing some definite ratio to the quantity of water ingested; rapidly progressive emaciation; a voracious appetite, sometimes amounting to polyphagia; gums red and swollen; teeth loosened; aphthous stomatitis; urine sweet to taste (who of you have tried this test?); and a host of other distressing symptoms gradually ending in coma and death. Now let me ask if this is a fair picture of the majority of the diabetic cases which are met in actual practice? If so, such experience differs from mine. It is true we have all seen cases which answered fully this description, even worse, but I ask candidly if the above picture is not that of the patient who has for years wandered from one physician to another, being treated for this and for that, first for the stomach, then for the liver, next for the kidneys, and so on until finally he has come into our hands at an incurable stage of the disease. All, perhaps, because a thorough and a careful analysis of the urine had been omitted at the outset.

Our authorities tell us but little about the early symptoms of the disease, so the young practitioner is taught to consider the above a typical picture of the diabetic patient. It is for this type of the disease, then, that he is expected to give his immense doses of opium, morphia, codeia, and so forth. Diabetes is usually classed among the incurable diseases, and even as great an authority as Osler says: "Personally I have never seen *recovery* from a case of true diabetes." This is from a man who has had wide experience both in hospital and private practice. Still with all due respect to the experience of Prof. Osler and others high in authority, I must believe that this opinion is founded upon an examination of cases, the majority of which must have been in the advanced stages of the disease.

As evidence of the curability of diabetes when recognized in its incipient stage, I will give briefly the history of two of my recent cases. Remember, I do not claim anything new or original in my method of treatment, nor will I say positively that *all* the symptoms I observed were caused by this diabetic tendency; but if I have made an error in my diagnosis I wish to be shown it, as it is but poor satisfaction to rightly treat a wrong disease.

However, the cases were, after a thorough investigation, diagnosed to be diabetic in their nature, and were treated as diabetic, and both have recovered. There is an old saying, "the treatment of ten establishes the diagnosis," so, in these cases the treatment, if nothing else would tend to confirm my judgment.

Case I. Mrs. T., aged twenty-nine years, came under observation in October of 1892. Consulted me principally for the relief of indigestion and headache. I found her fairly well nourished, but very anæmic, with furred tongue, nausea, marked anorexia, constipation, and liver somewhat enlarged and tender. On inquiry I learned that she had been under treatment nearly all of the previous winter and summer for what she termed "stomach trouble," but no appreciable change in her condition except for the worse. Up to the time of consulting me, no examination of the urine had ever been made, and let me suggest here that this is an omission we should never be guilty of. It seems to me that no diagnosis should be made in doubtful cases, or treatment entered upon, until a careful urinary examination has been made. It is a matter which is too often neglected in the hurry of practice, but which if carefully attended to, would clear up many of our previously obscure cases.

The obstinacy of her "stomach trouble" at once directed my attention to the kidneys, and this is what I found. She thought possibly there was a slight increase in the amount of water as she had

to rise at night often. Complained of a slight pain in the region of the kidneys, and also that she suffered from pruritus vulvæ somewhat. On October 19th I examined her urine and found the following: "Specific gravity, 1038; reaction strongly acid; color, a light amber; quantity for twenty-four hours, five pints; an excess of urea, no albumin; but of sugar a trifle over one per cent. To be more certain, I examined the urine every day for a week, meanwhile giving a placebo, and each time I found practically the same condition. Each time I employed three tests: first using the bismuth test, next Bartley's cannine-indigo and sodii carbonate powders, and lastly corroborated these with the old standby, Fehling's Solution, thereby eliminating all possibility of error. At the end of the week I began with the following:

℞ Strychine sulph.....gr. i
Podophyllin.....gr. viii.
Codoeia sulph.....gr. xx.
Papoid.....gr. xxv.
M. et ft. capsul, No. XL.
Sig. One after each meal.

You see there is nothing new or original about the prescription. I gave the strychnine and codeia for their well-known effects upon the nervous system, the derangement of which I think to be the chief cause of diabetes, and merely added the other ingredients to try and correct the condition of the stomach and liver the more rapidly. I do not know how the codeia acts in helping to control the disease, but I gave it as being the recognized treatment, and it undoubtedly has some special controlling influence over it. Be that as it may, my patient began to improve from the first under this treatment combined with a strict diet. Sweets and starchy foods of all kinds were forbidden. Gluten flour was substituted in place of ordinary flour. I saw her from time to time for examination each week. Her general condition improved rapidly, her strength returned, the quantity of sugar diminished gradually, the stomach and bowels regained their tone, the pruritus disappeared, the amount of urine lessened steadily, and night calls for micturition ceased entirely. This treatment was continued with gradually increasing doses of codeia and strychnine, until one-twelfth grain of the latter and two grains of the former were given three times a day, while the podophyllin was gradually withdrawn, as the liver resumed its normal functions. My examination of the urine the first of February, 1893, showed the specific gravity 1022; reaction slightly acid, color somewhat deeper, quantity for twenty-four hours two and one-half pints, urea normal, no albumin, no sugar. She at this time appeared and felt perfeclty well, with the exception that the anæmia still persisted. I then put her on Blaud's pills after meals, with a bitter tonic before. Under this treatment she rapidly regained her color, and at this writing she is apparently as well and healthy as ever in her life. I have examined the urine occasionally since then, but no trace of sugar has ever appeared. I have advised the husband to have her water examined at intervals for a year or more, and I think if ever sugar should reappear, that prompt treatment would be as satisfactory as before.

Case II.—Mr. S, aged thirty-eight years. The description of this case will not detain you long, as the treatment was identical with that of the previous case, with this exception that the strychnine was more rapidly pushed and the maximum dose (one-twelfth of a grain), was kept for a while by itself after all sugar had disappeared from the urine. This patient was a strong, robust, looking man and weighed one hundred and seventy-six pounds. He was well to do, was a good liver, had outdoor occupation, digestion good, bowels regular and was to all appearances a perfectly healthy man. He consulted me for the following symptoms: For several years he had noticed a growing weakness of his eyes, as he called it; could not confine his gaze to any one object for more than a few moments at a time; he had also noticed that sexual connection had quite a marked effect upon his eyes, claiming that for twenty-four hours or so after having sexual intercourse his eyes bothered him much worse than at any other time. He described the sensation as not an actual pain, but as more of a shrinking from light or bright objects.

He showed me in addition an oval ulcer on the edge of his tongue which had bothered him more or less for several years. He complained of a slight pain across the kidneys and about the loins, increased by riding. His kidneys acted rather freely, but he was never troubled at night. He informed me that he had his eyes examined in different cities, both in

the west and in the east by competent oculists, and he had been fitted with glasses by several but no relief of this condition. At the time of his visit to me he was wearing glasses adapted to hyperopic astigmatism. The right lens +50 +90°, the left was +25. He had also consulted several physicians relative to the ulcer on his tongue, and they had prescribed numerous local applications without any results. It was this last symptom, this sore tongue, which turned my attention toward the urine, as I have always made it a rule to examine the urine in all cases of obstinate sore mouth, and have several times been rewarded with finding there traces of sugar. The next day I examined his urine, and found as nearly the classical diabetic urine as ever I expect to see. Specific gravity 1040; reaction acid; one gallon passed in twenty-four hours; slight trace of albumin; urea increased; and lastly nearly two per cent of sugar. I submitted the urine repeatedly to the same tests as mentioned in the previous case, always with the same result, and afterwards during the treatment it was examined every ten days. He was put upon practically the same treatment as described in my first case, with the result that he soon began to improve in every respect. The sugar gradually diminished in quantity, finally at the end of about four months disappearing entirely; the specific gravity at this time showed 1024; the ulcer on the tongue healed completely without a particle of local treatment; his eyes gradually grew stronger and sexual intercourse ceased to have nearly the effect upon his vision as formerly, although this symptom has never wholly yielded.

As soon as the sugar disappeared from his urine, I discontinued the codeia, and gave him simply strychnia and quinine in doses of one-twelfth grain and one grain respectively, advising him to continue their use for several months longer. I have since examined his water from time to time and have invariably found sugar absent and his condition remaining good, with eye sight still improving under the use of the strychnia. At the time of writing this paper he informs me the improvement still continues, and it has been over a year since the codeia was dropped.

The symptoms of this last case are not such as are generally enumerated among those of diabetes, but if this disease was not the cause behind them, why should recognized diabetic treatment have such a marked influence in relieving them? I do not claim that sexual intercourse affecting the eyes is a symptom peculiar to diabetes, but I do not think that this disease was the direct cause of weakening the eyes so that this reflex ocular neurosis was more readily caused by sexual excitment.

## CONGRATULATORY ADDRESS.

THEOPHILUS PARVIN, M. D., PHILADELPHIA.

It is a pleasure to participate in these exercises. It is an honor to address this audience. But honor and pleasure are added in the duty of congratulating the Columbia District Medical Society upon its Seventy-fifth Anniversary.

The society was born in 1819! That was the birth-year of England's Queen, Victoria, and unto you, not by accident or by hereditary right, but by achievement, belongs the name of victory. Ten years earlier than the birth of this society was that of England's great Prime Minister, Gladstone. So too, in 1809, England's greatest poetess, Elizabeth Barrett, was born. That same year gave our country one who was destined to be among the wisest and most patriotic of Presidents, Abraham Lincoln. It was the natal year, too, of one who, entering the medical profession, did more by his contributions to a medical journal half a century ago, to avert "a private pestilence" from mother and her new-born, than all the obstetrics in the country; who for many years was an eminent teacher in Harvard, and still more distinguished for his contributions to literature, so that his name is honored wherever the English language is spoken — Oliver Wendell Holmes. Your organization is ten years younger than he who guides the destinies of one of the world's greatest empires— ten years younger, too, than he who is one

of the best and most honored of the world's teachers, and who, by his recent lines upon Francis Parkman, has proved that his mind is not clouded or his heart chilled in his ninth decade.

Yet seventy-five years is a long time in the history of a society in this nation, that only a short time since celebrated the centennial of the adoption of its constitution. The College of Physicians of Philadelphia is but thirty-two years older. The number of its active Fellows is 281, and since its organization these have been 586. Its chief pride is in its library, now numbering almost fifty thousand volumes, and its annually published Transactions. You have had 564 members, and now have 214. In view of such facts one must question the truth of Addison's remark, "We may lay it down as a maxim that when a nation abounds in physicians, it grows thin of people." I am quite sure that I echo the sentiment of every Fellow of the college in hearty congratulation for what you have accomplished, and in bidding you God-speed.

But for the moment I must speak, not for one, but for all the medical organizations invited to participate in this commemoration, in their name bearing meed of praise, and bringing new laurels to crown you this festal night. Nay, more, I imagine there comes from the entire profession of this country, from Maine to Texas, from Massachusetts to California, borne hither from either ocean, sweeping over mountain and valley, over city and hamlet, over prairie and forest, lake and river, harmonious and enthusiastic plaudit.

Every student of American medical literature knows well how many valuable contributions have come from members of this society, come, most of them, probably because of its existence. Washington men have been the authors of several medical text-books; among the more recent, one upon materia medica, the other upon obstetrics, have received deserved fame and position. Among the men who have helped me in the special department of medicine, which for years has almost exclusively engaged my attention, several of the Washington profession, some living, others dead, are included.

Thrice the great National medical organization of this country, the American Medical Association has chosen its president from the members of this society—these were in order, Lindsley, Toner and Garnett; minor positions in the association are every year assigned to Washington men.

It is hardly expected that I should speak of the more eminent dead of your number, among these, Noble Young, the Mays, Bohrer, Thomas Miller, Sewall, W. P. Johnston, Stone and James C. Hall. Of the last in this list permit me a word. I am informed that he attended more eminent men than any physician ever living in this country. At one time in his very active life he was the physician of every Judge of the United States Supreme Court, almost every Senator, many Representatives, the President and his Cabinet, and of nearly every Foreign Embassy. He was not only a great and successful practitioner but a true philanthropist, relieving distress kindly, liberally, unostentatiously. In doing alms he obeyed the Divine injunction, "Let not thy left hand know what thy right hand doeth." We may call him and his compeers,

> "The kings of ancient days,
> The mighty dead, who live in endless praise."

Pardon me if, prompted by many years of personal friendship, I refer by name to two of the living members of the Society in words of loving, and, I believe, just, praise. You, Dr. Busey, have recognized through your many years of busy life, that you were "a debtor to your profession," and honorably and well have you discharged that debt by contributions of sterling value to its literature, and by always seeking its interests possibly sometimes at the sacrifice of your own, but even then, and thus helping others to believe that, as Renan has said, the noblest thing in life is sacrifice. In view of your life and work, permit a layman to repeat a Pagan prayer, first uttered nearly three thousand years ago—may it prove prophecy as well as prayer:

> "So peaceful shalt thou end thy blissful days,
> And steal thyself from life by slow decays;
> Unknown to pain in age resign thy breath,
> When late stern Neptune points the shaft with death;
> To the dark grave retiring as to rest.
> Thy people blessing, by thy people bless'd."

One whose genial manners, generous heart and kindly deeds have endeared him to all who know him; one who has made for himself a name in the profession by important historical researaches, and by

his large and valuable collection of medical works donated to the public,* has taken no step to perpetuate his name by descendants, unlike the first May, whose son became a physician, and whose son's son is now treading in the footsteps of illustrious father and grandfather. But let us find comfort in the words of Bacon: "Certainly the best works, and of greatest merit for the public, have proceeded from the unmarried or childless men, which both in affections and means have married and endowed the public." Married and endowed the public! None forbade the banns, when this member of your Society, not letting his "thoughts end with himself," and not "accounting future times impertinencies," married and endowed the public. Though Dr. Toner has never "given hostages to society," may he long be spared to contribute to public and professional interests, still wearing his favorite flower, a bachelor's button!

How Washington has changed since your professional progenitors instituted this Society. A town of 12,000 is now a city of more than a quarter of a million. I have read that not long before 1819, congressmen had difficulty in finding lodgings, and that the wife of the President at one time, used the audience room of the White House as a place for drying clothes. One can believe that now it is difficult for many lodgings to find congressmen, and, as to location for drying White House washing, that if Mrs. Cleveland were to do as Mrs. Adams did, there would be a social, if not a political convulsion, and a very uncivil war. There have been great changes here and elsewhere since 1819, changes affecting material comfort, changes in manners, customs and external observances of society. But all departures from the old are not necessarily improvements, and all re-formations are not inevitably reformations; changes may be external, superficial, and not involving essential character and nature. "When Plancus was consul," was our social life worse than at present? The bowie knife and Bladensburg are memories only now, but are assassins and stilettos unknown at the end of the century, and are those who carry the poison of asps under their tongues all dead? Are there not still selfish, unscrupulous schemers, or vile ingrates who rob, or revile a benefactor, shrinking from no falsehood, however base to blacken his name, as long as they can work in the dark. When "Plancus was consul" possibly they would have been promptly called to account for their evil words and deeds. Children may not play marbles upon the front pavement on Sunday, especially when the devout are going to or returning from worship, but the back yard possibly is crowded by urchins, careless of the concealed fractures of the day that escape clerical observation and diagnosis. "When Plancus was consul," was the doctor a better man than to-day, better qualified for his work, with a nobler ideal of his calling, scorning "the tricks of the trade"—the indirect advertising through newspapers for example, which we now sometimes see, a doctor rushing into print upon the slightest occasion, or making known to reporters, eager for news, his professional exploits? There are doctors who will do anything to get talked about, to have public attention directed to them in order to secure public patronage. Yes, before those days of Plancus, to which reference has been made, we are told of doctors who "ply for employment like scullers at Hungerford stairs." Are there not doctors who do this now? Read, too, Smollett's story of "Count Fathom" starting in practice in London,† and the observation of almost any one will give him instances of its essential repetition. The count bought a chariot for "equipage, though more expensive than his finances could bear, he found absolutely necessary to give him a chance for employment; as every shabby retainer to physick in this capital had provided himself with such a vehicle, which was used altogether by way of a traveling signpost, to draw in customers; so that a walking physician was considered an obscure peddler, trudging from street to street, with his pack of knowledge on his shoulders, selling his remnants of advice by retail.

*Congress in acknowledgment of the doctor's present to the Nation of 28,000 books and 18,000 pamphlets, ordered both his bust and portrait to be made and placed in the Congressional Library—a just and honorable recognition of his great and generous gift.

†Dr. Samuel Johnson, in his biography of Akenside, after stating that this doctor and poet never attained professional success in London, remarks: "A physician in a great city seems to be the mere plaything of fortune; his degree of reputation is, for the most part, casual; they that employ him know not his excellence; they that reject him know not his deficience. By any acute observer, who has looked on the transactions of the medical world for half a century, a very curious book might be written on the "Fortunes of Physicians.'"

Though so many changes that are merely external, not touching the heart, not affecting the real life and character, but having to do merely with the clothes that are worn, have occured I believe in social, as much as in the certainties of medical progress: Faith in man, faith in God, would perish if I did not have this trust.

Certainly medicine has its imperfections, its defects and failures. But let us recall what one of our guild, Sir Thomas Browne, said in answer to this reproach: "There are not only diseases incurable in physick, but cases indissolvable in law, and vices incorrigible in divinity."

It may be objected there are quacks in medicine. Such fact is not peculiar either to the age or to the calling. Izaak Walton wrote more than two hundred years ago, "There are too many foolish meddlers in physick and divinity, that think themselves fit to meddle with hidden secrets, and so bring destruction to their followers." More than one hundred and fifty years have passed since Smallette declared, "We have quacks in religion, quacks in law, quacks in patriotism, quacks in government."

Our call my brothers of the profession, is to do our duty to our patients, to our profession, to society, and to God, come reward or reproach, whether our pathway is upon the mountain or in the valley, to live noble lives, even though making sacrifice and enduring trial, bravely and conscientiously seeking that the world shall be better on account of our living in it. When in Scotland the fiery cross was borne swiftly as strong and agile limbs could go, to the nearest village, and there given in charge of the oldest male representative of the family, the only word spoken was to tell the place of rendezvous, and it was his duty to carry it to the next village, there finding a new bearer of this consecrated emblem, and thus on until all the members of the clan were called to the mustering-place—no one could refuse the duty of bearing this cross—new-made bride or unburied father was not excuse—and unto those who failed to respond to the call, the cross became a cross of shame. The doctor bears a cross of fire in life's race, and only when that cross "drops from his nerveless grasp," and his weary feet falter, and forever fail, is his duty done.

Medicine comes more and more to the front every year, and especially is its power of preventing disease more distinctly recognized. When will our national legislators acknowledge the fact that the health and lives of the people are as important objects for their consideration and care as post offices and pensions, and the products of forest and farm, of mine and manufactory? When will they establish a department of public health, and place it under the control of a competent medical man, who shall hold equal rank and dignity with the heads of other departments of government? This duty is imperative, and this action ought to be immediate.

In final words I might eulogize the work of the physician, and exhault the honor of medicine. And to this end there could be adduced from Pagan and Christian writers, from the wisest and best of every age, testimonies that would be conclusive. But time does not permit, and I only ask you to listen to the eloquent words of Cardinal Newman, and see how appropriately and necessarily medicine is embraced in his large inclusion: "All that is good, all that is true, all that is beautiful, all that is beneficent, be it great or small, be it perfect or fragmentary, natural as well as supernatural, moral as well as material, comes from God."

---

**Very Small, Indeed.**

The smallest baby yet reported was born in Killingworth, a village about eight miles west of this place. The parents are Swedes. The father is employed by a farmer cutting timber and weighs about 190 pounds. The mother is a stout, healthy woman, weighing perhaps 160 pounds. The child is a male as perfectly formed as any being can be, and on its birth weighed only eight ounces.

Its face is about the size of a horse chestnut. A ring worn on the little finger of its mother was easily slipped over his foot nearly up to the knee. It is the opinion of the attending physician that the child will live. The child is so small that three of its like could play hide and seek in a cigar box.—Ex.

## A BRIEF STUDY OF SOME ANCIENT EPIDEMICS AND THEIR RELATIONS TO INFLUENZA.

### WITH NOTES OF THE EPIDEMIC OF 1893-94, AND RECENT METHODS OF TREATMENT.*

ROLAND G. CURTIN, M.D., AND EDWARD W. WATSON, M. D.†

The question of the identity of the cases of excessive sweating seen frequently in the last four years with influenza, is scarcely open to dispute; since the cases observed, either the initial symptoms were those of influenza or the sweating was evidently a sequel to a well-marked influenzal attack. All influenza, as a rule, was marked by relaxation of the skin, after the initial period and the subsidence of the earlier symptoms, and this often continued in a mild form (sweating on slight exertion, sweating when in bed, and on slight exposure to cold) for days and weeks. But the cases directly under consideration were marked by such excessive relaxation, and so entirely different from any previously observed in any other disease (except, possibly, in rare cases of convalescence from malarial and rheumatic disease, from which latter they differed in the odor of the perspiration), that they could not but strike the observer as unique.

We might add that since the epidemic sweating in phthisis has been much aggravated, as well as in other diseases. This may be explained as a condition like the other general catarrhal conditions, a hydrorrhœa, or, what might be termed for the want of a better name, a cutaneous catarrh of the sudoriferous glands.

In the early epidemic of 1889–90 a number of cases were observed in which there was this tendency to a remarkable degree, continuing for weeks, without emaciation or exhaustion or induced anæmia. These cases often perspired to such a degree that in cold rooms they seemed enveloped in steam, and at times as they were observed in bed, the ear which was uppermost and the corresponding hollow of the cheek were often full of water. At times the sweat extended into the mattress, and from below upward the moisture would outline the form of the patient on the coverlid.

In one case this condition lasted one week; in another four weeks; in another three months; in others five months; and in two six months; and one case affected a year ago, even now on slight exposure to cold continues to sweat profusely.

Many practitioners alluded in conversation, or in periodical medical literature, to similar cases, one writer in the South reporting an epidemic in his locality of what he termed a "sweating fever," and in the communication referred to asked information as to its nature. From the description given it was evidently something more than ordinary epidemic influenza, or simple catarrhal fever as usually observed, but resembled closely some of the cases seen by the writers in the past four years. Our cases generally began with an attack of influenza, or had some of the complications and sequelæ of influenza, viz.: the pulmonary or cardiac symptoms (angina pectoris, pericarditis, and heart failure), or affections of the peripheral nerves of one or both arms, rheumatoid pains, meningitis, diarrhœa, and other catarrhal affections and insomnia. With this profuse sweating the temperature night and day was generally near the normal—often either merely a little above or below. In one case for two months perspiration continued with the temperature from ½ to 1° below normal. Another case was noticed similar to the above.

It is very easy to understand from what we have seen of influenza, that in different periods of an epidemic, different structures may be predominantly affected, viz.: an epidemic of influenza, in which cardiac symptoms predominate, might, under depletion and the unwise use of depressants, come to resemble the so-called "cardiac disease" of ancient times; or where the vasomotor nerves especially suffered, under like improper management—over-heating, excessive covering, and the abuse of diaphoretics—a genuine "sweating sickness" might be produced; or the extreme

* Read before Phil. County Med. Soc., February 28, 1894.

† A portion of the paper will be published in the Transactions of the Pan-American Medical Congress, 1893.

sweating producing copious miliary eruption, we might with justice call it the "miliary fever." In fact, the recent epidemic has by turns exhibited the characteristics of the various disorders described and preserved to us in the writings of several ancient observers, and it may prove of some value to contrast these characteristics with those extant observations.

The following shows what symptoms and conditions were common to all the above-mentioned diseases:

They were all—

Epidemic.

Sudden in onset.

Commenced with chilliness or rigor.

Accompanied by more or less intense headache and fever.

The strong were attacked rather than the weak.

The comfortable classes rather than the extreme poor.

All were attended by sweat of unpleasant or fetid odor.

Occasional varied hemorrhages in all.

Vomiting or purging at times in all.

Meningeal and other nervous symptoms.

Nervous prostration and prickling pains.

Sudden paralysis, heart excitation, heart failure.

Rheumatic pains—gout symptoms.

All were infectious or contagious.

All had catarrhal symptoms, and sudamina or other eruptions of a miliary character.

In all the atmospheric conditions favoring spread of the disorder were fogs and humid atmosphere.

Stimulants were in all beneficial.

All had heart complications.

Sudden excessive secretion of urine and sweating came together.

All were alike sensitive to cold and draughts.

Checked perspiration caused diarrhœa.

Relapses were frequent.

Mortality light in acute influenza, heavy in all others (this can be somewhat accounted for by modern therapeutics and hygiene), and much in this respect depends upon the pecularity of the epidemic.

The sequelæ in all were very similar; the general constitution was shaken—dropsy, consumption, heart failure, low forms of fever followed, and insanity and suicide were frequent.

A brief study of these data will show how very analogous, to say the least, were all these diseases. Certain marked peculiarities not found in other diseases generally, were common to all. The most marked is sweating, so that from the descriptions which have come down to us one could see little reason why the name of "sweating sickness" might not have been applied to any of them (at least in some of their extreme and varied manifestations). The group of nervous symptoms common to all is very striking and peculiar. These diseases seem to have been all recognized as contagious or infectious, and occurred as epidemics, and often seemed to supplant (follow or succeed) one another rapidly. The rheumatoid and gouty symptoms, the heart complications, while in some more prominent, existed in all. The description of the cardiac disease might be applied, line for line, to some of the severer cardiac influenzal cases recently met with, and at times associated with these was sweating, as profuse and overwhelming as that described in the "sweating sickness" of antiquity—lacking only its extreme malignancy.

The sequelæ seem to closely resemble each other in all, and the atmospheric conditions, fogs and rain, and a warm, moist, wet state of weather seem to have in all been exciting causes.

We are almost forced to the conclusion that if not identically the same, these diseases belong to the same group or family, and are intimately correlated. They seem to have preceded, replaced, or followed each other in close succession through quite an extended period, or prevailed in different countries almost simultaneously, at times seeming to be conveyed by contagion or infection. Of their real origin we have no more accurate knowledge today than our forefathers had, but it seems a reasonable and probable deduction that there exists almost constantly in the world a form of influenza (general transient and mild) known to us as the cold we "catch" under various atmospheric causes, which under vicious atmospheric conditions and climatic variations is capable of developing in one or another direction—and so into the various forms which we have been considering. If not all the same in origin, when once their microbic cause is really isolated and identified beyond a doubt, it

will, in all probability be found to be but varying forms and outgrowths of the same germ, or that varying germs exist (as in other cases is already recognized) of similar influence, causing those different diseases which may be considered as but malignant varieties of that influenza with which the world is at present so unpleasantly familiar.

### EPIDEMIC OF INFLUENZA AS OBSERVED IN PHILADELPHIA DURING THE PRESENT YEAR (1893–1894).

During the years of influenzal epidemic disease since its appearance in 1889, its variations in intensity may be summed up roughly as follows:

1889–90, very severe and fatal.
1890–91, mild.
1891–92, marked severity.
1892–93, mild.
1893–94, very marked, but not so widespread and fatal as in 1889–90.

From this it will be seen that every other year it has been severe. The two winters when it assumed a milder form were of the five the most severe in temperature, 1890–91 having an early cold December which seemed to throw its epidemic outbreak toward the spring; 1892–93 being continuously cold, the epidemic outbreak seeming to be worse when favored by a mild fall and early winter and great and frequent changes. This past winter the outbreak began somewhat early, about the middle of December, the usual number of isolated cases having occurred through the autumn. A certain amount of the year's outbreak seemed due to visitors returning from Chicago, where it prevailed in a mild form.

The pulmonary attacks seemed milder, though grip lung was not infrequent. The expectoration was more inclined to be purulent. Even among the aged the fatality was light; one of the authors encountered seventeen cases with one death, and that in a case complicated with pleurisy and effusion and catarrhal nephritis. Of the sixteen recoveries, some of the ages were eighty-six, eighty-two, seventy-eight, seventy-four, sixty-eight, and sixty-four years. The constitutional symptoms did not end by crisis, but continued some time after the local symptoms had subsided.

Diseases other than influenza have shown less of the influenzal stamp than in previous winters, but the traces of the epidemic were still visible when looked for. Considerable vertigo, alternate creeps and sweats, rheumatic pains in the limbs, insomnia, and occipital headache accompanied disorders where such symptoms are not ordinarily met. Temperature ranged lower on the whole than in past years. In bowel catarrhs much colitis (with gelatinous froth, with or without blood) was frequent.

The vertigo was sometimes transient but often very persistent; change of posture induced it—throwing back the head, looking to right or left—sometimes such movements of the head even produced insensibility. This vertigo was often persistent; in one case for a year, being worse on exposure to cold, and finally disappeared with an attack of pulmonary catarrh.

Many cases of stiffness and pain in the back of the neck occurred during this winter's epidemic, some with considerable fever. Constipation occurred in almost all prolonged cases of influenza, was obstinate and marked peculiarly by a tendency to "throbbing in the bowels." This constipation was not due to hardened feces or scanty mucous secretion, but rather to an imperfect power in the muscles of the bowels, the expulsive mechanism, or both.

During the mild weather of the winter catarrhal diarrhœas were more common, associated often with vomiting, which was an unusually frequent symptom during the entire season while during the cold spells pneumonia was most frequent.

As a typical instance of the chronic cases of influenza of the mild nervous variety we might give the following, very recently met with:

A. B., travelling salesman, has had the following symptoms for three years since an acute attack of influenza. He has tickling chilliness of the legs, followed by a cold clammy perspiration on exposure to draughts and cold, and at times when in bed; insomnia or disturbed dreaming sleep, especially in the morning. When awake he is very despondent and irritable; hands numb at night; tinnitus; rheumatoid pain; varying soreness of the eye-balls and abdomen, and a catarrhal dyspepsia.

Temperature 97° to 98°, A. M., and 99° to 99.5°, P. M. He feels much better toward night. Such cases only require excessive fatigue or depressing emotions

or great exposure to produce some of the severer phases of the malady meningeal, pulmonary, cardiac, gastric, intestinal, renal, etc.

*Treatment.*—In the treatment of influenza some changes have occurred. Some progress must be made in the management of a disease so long and constantly present with us. Not only do our necessities lead us to employ new measures, but diseases themselves change, and influenza is not an exception to this rule. If any general and marked change in the behavior of the disease has occurred it has been in the manifestation of a greater susceptibility on its part to the action of old remedies and time-honored measures. In fact, there has been a revival of a number of old-time remedies which have been for a score of years discarded as useless, and which now in our epidemic experience lead us to conjecture that our predecessors were not such fools as we supposed.

New remedies, too, which were unknown to the world in its older epidemics of influenza have been used with advantage, but in general the tendency has been to treat influenza and its sequelæ on the old lines of treatment, and with far more success than in the years since 1889, and we think that this tendency has gradually increased since that year.

For acute influenza, the salicylates and salicin still hold their popularity, which only increases with time and use, especially since we have in the market the pure salicylates of Merck and others, which certainly do not depress the system as did the crude article formerly used; phenacetin combined with these still holds its popularity in early stages, while for the cough in the bronchial form, codeine is more and more used in small doses.

For the marked initial chill, spirit æth. nit. with spirit æth. comp. and chloric ether afford a valuable aid, and when these fail to arrest the often convulsive movements and restore the overwhelmed centres, amyl nitrite and nitroglycerin have often proved successful. Opium in the form of onset accompanied by severe pain has given far better results than in former years, with apparently no bad effects; terebene, turpentine, oil of sandal, and oil of cubebs, as expectorants, and ammonium chloride in the later stages have been relied on; but for the persistent tickling, pharyngeal, laryngeal and tracheal cough, all remedies administered have often failed, but immediate success has been met with by employing a spray of liquid albolene and menthol, five grains to the ounce or more.

Where the grip lung with its psuedopneumonic physical signs made its appearance, counter irritation by mustard has seemed best. The pleurises, by the way, which have been encountered this winter were almost invariably plastic and subsided readily on counter irritation and salicylates.

The purely gastric influenza was treated by cocaine, gr. ¼ in ʒij of aq. chloroformi, as frequently as every hour, while the diarrhœal form was managed readily in most cases by bismuth and opium, cocaine being added where vomiting continued, and in the obstinate cases, and in fact in all the cases which seemed severe at the onset; the bowels were daily flushed out with a one per cent. solution of creolin or boric acid. The effect of this was often marvellous, especially in cases attended by high fever, where the subsidence of temperature was almost immediate.

For the resulting prostration and loss of appetite, full doses, ʒij of bitter tinctures, as cinchona comp., cardamom comp., calumba and gentian, with full doses of strychnine were given; sometimes caffein was added. Alcohol, cod liver oil, hypophosphites, iron, and malt still hold their own, and seem the best known agents for the repair of wrecked and ruined constitutions. Opium has been found to be the most useful drug for the meningeal irritation, or mild or threatened meningitis. Vini iodinii comp., suggested by Dr. Potsdamer, has proved of great service in the chronic cases of all forms of influenza. As to the treatment of the profuse and protracted sweating, we might as well say that after trying all recommended remedies, all equally failed of satisfactory results. Fair trial has been made of the following remedies; atropine and belladonna, quinine and sulphuric and camphoric acids, agaracine, picrotoxine and ergot; small doses of jaborandi seemed to do a little good; also alcohol in moderate quantities; also sage tea and boneset. Externally, alcohol and alum were of some use; internally alum failed. The power of the vasomotor nerves seemed often so impaired that remedies had little or no effect.

# SOME OBSERVATIONS ON INFLUENZAL NEURITIS.*

EDWARD W. WATSON, M. D., PHILADELPHIA.

The field of influenza is almost inexhaustible. Some portions of it have received far more attention than others. If any part can be said to have been neglected it seems to be that of neuritis, in which we have often the most notable failures, and in which also there possibly lies concealed the secret of its pathology and the clue to its mystery.

The different nerve affections of this disease might, if we chose, be divided into three main divisions—general nerve irritation, local functional disturbances, and local neuritis. We might consider the general aching and pain which marks the onset as the first. Functional neuroses may be met with at any period of an attack, but localized neuritis are rather sequelæ than early symptoms.

Now, the main question at issue is, whether in a localized neuritis the peculiar process gains special access to the separate nerves, or even to the nervous system generally; or whether in all influenza, as shown by its initial symptoms, the nervous system is always the seat of such process, though in so benign a degree as to escape notice; or, as a third view, whether while the nervous system is always invaded the nerves of organic life are not generally the principal sufferers, and those of voluntary motion are least and so escape notice.

We should premise that influenza, even in its acute epidemic form, is in all probability a much longer disease than is generally supposed. Early recoveries from pulmonary and abdominal forms are such only in seeming, as shown by the lingering character of the recovery, and the long period during which tonics and stimulants often fail to overcome the exhaustion and inertia. Further, in general, when recovery from acute disease sets in, the whole world brightens to the convalescent, sleep restores, food nourishes, and tonics tone; but after acute influenza there is a long period of semi-recovery—a lethargy of the system in which remedies fail to act.

Now, if in such a case of supposed convalescence exertion, exposure, anxiety are endured, we have, if early in the case, a so-called relapse or more properly a recurrence in some new organ or structure, generally internal; but if later in the convalescence, we are more likely to have an external peripheral neuritis. A central neuritis may at times occur, as in the unfortunately frequent heart failures; but more commonly if walking has been excessive we find a sciatica, or an extension of the disease in the line of the sciatic to the calf, heel, or toe. Where the arms have been overstrained in gymnastics, reaching, lifting, driving, we find a brachial neuritis—generally descending from the shoulder. These attacks should be discriminated from those muscular pains which appear much earlier in muscles in the neighborhood of organs affected by influenzal catarrhs, as the trifacial in coryza, the region of the neck in catarrhal pharyngitis, lumbar pains in renal catarrh, epigastric pain after gastritis, etc.

Of the external neurites the brachial is the most common. This occurred in nearly one-half of our cases; then in order of frequency came the intercostal, sciatic, epigastric, cervical, lower abdominal. The onset of the brachial attack is generally sudden, and often at the first the disease seems reluctant to locate, the pains radiating in the neck and thorax, axilla, and down the arm; soon, however, the painful point will be found quite fixed on the anterior aspect of the head of the humerus (shoulder). Associated with the pain come numbness and tingling in the course of the nerve, and the shifting character of the numbness, etc., from radial to ulnar distribution, or *vice versa*, shows how intermittent is the obstruction and interference with the nerve current (action). These shifting sensations are by no means to be taken as indicating that the active process has extended to the fingers, but that where located it obstructs or interferes with certain nerve fibres distributed to the fingers.

The actual discernible alternation in the course of the nerve is found most frequently in the region of the biceps, though painful points can at times be made out at and below the elbow. The biceps, however, most frequently in protracted cases

*Read before the Phila. Co. Med. So., February 28, 1894.

hardens with a doughy hardness and enlarges. In unfavorable cases it afterward wastes very considerably. Similar wasting has been observed in other regions where other nerves are in like manner affected. We are inclined to believe that if proper care be early taken the condition tends to somewhat rapid recovery, but when the arm is used to any extent, and where with this there exists a gouty history or a gouty inheritance, under undue effort, and imperfect nerve-supply, the muscles go into a state of tonic spasm or contraction and the nerve exhausted in its efforts to transmit the force demanded becomes locally still more involved; rarely an eruption of shingles occurs in the course of the affected nerves.

We may as well admit that this condition is somewhat beyond direct and positive therapeutic aid; how serious the condition of the nerve may at times become has been of late shown by careful post-mortem examination. How very hopeless the restoration of function may be, is shown in the series of cases reported by Dr. Ferguson, of Toronto, in the *Medical News* of January 6th of this year (1894), for although no mention is made by him of the fact that his cases were any of them of influenzal origin, though he mentions in one case that influenza had preceded, we think that at least three of the five bear evident marks of being due to that cause. Again, a study of the behavior of these diseased nerves under certain circumstances, tends to throw a partial light into the general gloom. Again and again after applying the interrupted current the pain has been rapidly relieved, but within a few hours a more violent attack has occurred in a more important (and serious) locality—from the arm to the lumbar spine, to the cervical region, to the precordial region, to the other arm; sometimes exhaustion and faintness; sometimes intermittent pulse has been noticed. The same experience has been encountered in the employment of massage of the affected arm, while in other cases in later stages, or in the same case later in its course, both agents have been of the greatest service and conduced to permanent recovery. In three cases long localized pain in the epigastric and abdominal regions has yielded at once and permanently to one short application of the battery.

It would be well also to notice those cases of intra-thoracic and intra-abdominal neuritis attended with much more threatening symptoms, where change of position leads to failure of pulse and loss of consciousness, or to profound nausea, or to respiratory failure, which as they gradually recover seem to do so by an exodus of the morbid condition from within to without; where an emerging neuritis of arm or leg seems the surest harbinger of escape from a fatal illness. The influenzal process seeming to traverse deep-seated and vitally important centers and nerve trunks and emerge to those of less vital moment. This has been a somewhat common termination of many cases of apparent neurasthenia, which should, however, be discriminated from the neurasthenia with which we have of late years—before the influenza epidemic—become so unfortunately familiar, for between them there lies a great difference. In either case the patient is neurasthenic, but has arrived at that condition by quite a different road. The typical neurasthenic has exhausted centers, and we believe may have injured nerve trunks even, by excessive and prolonged exertion or sudden overstrain. The influenzal neurasthenic has the nerve centers, perhaps the communicating nerve trunks, certainly occupied and rendered useless for a longer or shorter time by a progressing disease. In the former case it is but necessary to accummulate force and cause its conveyance to mechanism which we put in the best possible order; while in the latter case we must await the disappearance of the disease before we can hope for improvement; this, we think, supplies the reason for the behavior of the patient under massage and electricity.

In summing up therapeutic results, we can say that rest is an absolute necessity; that electricity has benefited many cases, generally ones of long standing, but has injured, at least for a time, many early cases; and that massage, though less powerful for good, has been only less powerful for evil; while counter-irritation has been disappointing, and repeated blistering has repeatedly failed.

In the early days of the attack heat has been often valuable, where the whole limb could be enveloped in moist heat as by formentation, or swathed in hot flannels, or placed in hot water. But no drug has given reliable results. When improvement has been most pronounced, then re-

lapse and disappointment have been most certain. If to this sweeping statement there be any exception, it is in favor of arsenic in very small doses frequently repeated. Of general systemic treatment, such as strychnine and phosphorus, quinine and alcohol, and cod-liver oil, we are not speaking—these may generally benefit the patient, appetite may increase with assimilation, strength and the general appearance of health may return, but the arm or leg be much the same. Mercuric bichloride, iodides, and bromides have given no results; salicylates and salicin have failed to relieve—they may have prevented. Morphine pushed continuously has seemed to shorten the attack in many cases if given early, possibly by enforcing that rest which is so vitally important to cure; atropine, which controls some of the manifestations of nerve disorder, as the chilliness, excessive sweating, and the pulmonary conditions, is a failure in the neuritis under consideration. Hypodermatics of atropine in the painful points or into the affected muscles (biceps itself) have given no good results. Locally, belladonna, menthol, ichthyol, and mercurial ointment have been used with apparent benefit. But viewed in the most cheerful light treatment is unsatisfactory, and prevention is better than cure. Prevention—if the ideas expressed in this paper are correct—by early and continuous rest continued long enough to allow the system to react and the disease to naturally terminate; and when exercise is permitted, with such restrictions as to avoid tire, general or local, and this will require such confidence on the part of the patient, and such an education on his or her part also, that it will, I fear, be long before the disease is banished by preventive measures.

The treatment of an internal neuritis of a nerve supplying a vital organ resolves itself into a treatment, so far as possible, of the organ involved. To take one case as an illustration—the stomach. All are familiar with the fact that digestive difficulties have been unusually frequent of late; they have taken the form of delayed digestion, with emesis, pyrosis, and eructations. In the majority of these we have found the difficulty to culminate at night, to be least in the early morning. All of them if carefully questioned will give a history of influenza as a starting-point, generally influenza of the gastric form, though perhaps not recognized as such by the patient; they go back to an attack of chilliness and fever with vomiting, fever with loss of appetite, fever with diarrhœa. Following these there will often be a history of gastric pains excited by food; often a distinct account of a peculiar pain or mild gastric pang coming on at short intervals after eating, and peculiar in that it starts in the region of the pylorus and travels in a wave or thrill in the direction of the greater curvature from right to left, dying out gradually as it travels, only to be followed by a succession of such pains. As these pains diminish with days and weeks the patient discovers that he has dyspepsia, and if appetite returns he begins soon to suffer after meals in a different way with acute indigestion. After a time the gastric soreness is almost continuous, and nights and days are passed in great distress, and speedily weakness and emaciation occur. Now, these cases seem to be due, judging by analogy, to a condition of the pneumogastric or splanchnics similar to what we have been noticing in external nerves a long-continued state of diminished action of the gastric muscles, owing to their supplying nerves having been occluded or interfered with by influenzal disease.

Those who have attempted to relieve these cases (which show no evidences of dilatation and rarely of any gastric catarrh) will bear witness to the general uselessness of the old lines of treatment and the new ones as well. They resemble cases of dilated stomach with pyloric obstruction, but are most probably atonic stomachs with normal pylori, in which the force of contraction is insufficient to expel the digested food, or where the almost unknown nervous mechanism of the pylorus is in some way at fault.

When this condition has become aggravated and distress is constant washing out the stomach will undoubtedly give relief, but acids, alkalies and bitters, pepsin and peptonized foods avail little. From careful observation of the general condition, the observer must be led to conclude that a defective innervation and consequent painful and feeble action of the stomach is the real difficulty, and that the retention of food too long leads to the formation of digestive products toxic to the economy and irritant to the organ itself. Intense irritability is often shown by emesis where

the matter ejected seems quite normal; faulty innervation by the cases when digestion can go on normally for days in the recumbent position, but where the patient on assuming the upright or sitting posture invariably vomits after a definite period of time—half an hour or an hour. That increased irritability is one cause of the delay and distress is shown by the character of the only drugs which seem to afford relief. Chloroform, cocaine, bismuth, alcohol and the bromides—these, especially the latter, will in many cases restore appetite, relieve distress, and banish indigestion; but when they fail we seem left with but one alternative other than washing out the stomach, viz., to give the organ as long and continuous a rest in the twenty-four hours as is possible, in order that it may store up power enough and free itself. This gives immediate relief and so is willingly pursued by the patient.

As a formulated plan of treatment, it is best to begin with twenty-four hours of semi-starvation, interdicting all food except a gill of hot milk three times in the first day; on the next day ordinary diet can be given in full amount at the morning and noon meals, but after 2 P. M. nothing until the next morning at breakfast. In a few days the appetite will accommodate itself to the circumstances. The stomach relieved and free from pain does its work in better time and manner, and emaciation ceases and weight is rapidly regained. The weight of the patient should be carefully taken at intervals of three days, and when there is no more increase, where further increase of weight is desirable, then more food must be given; and first a return to some form of evening meal should be tried. Milk or a farinaceous food with milk is best borne, and if all is well the patient can return to his former habits in regard to eating and is cured. If, however, as is often the case, this cannot be done, the extra food may be given in the forenoon—*i. e.*, breakfast at 7 A. M. or earlier; lunch at 11 A. M.; dinner at 2 P. M.; in this way as much food can be taken as ever but without distress.

When from the beginning the distress has been absent at night and severe during the day—as, for instance, where the most serious suffering is experienced after breakfast—breakfast itself must be omitted or reduced to a cup of milk, while dinner and supper are taken as usual, the necessity being for some period of rest continuously in the twenty-four hours of from fourteen to sixteen hours. The lighter cases, where the mid-day meal alone is followed by indigestion, can generally be reached by bromides and a bitter, or by omitting the mid-day meal altogether, even adding additional food at bedtime if the scales show no gain.

How successful this plan of treatment is, how much relief it affords, and how notably the patients gain in weight and spirits, will be realized by anyone who will try it. Crude enforced starvation has always been one of the main remedies of empirics and charlatans in dealing with indigestion, but in the method we have described we believe it to be scientific and valuable.

Cases illustrating the success of this plan, which for the want of a better name we might term "digestive rest," could be given in considerable numbers were it desirable to add to the length of this paper; let it be sufficient to say that in genuine post-influenzal dyspepsia, the writer has met with very few failures save where undoubtedly the directions were not followed. Where the case is severe and the patient can be induced to give the plan a three-days trial, his own relief will be a sufficient inducement to pursue it as long as is necessary.

Rest, then, of all remedies seems most fitted for the relief of influenza from its onset to its remotest sequel. There seems always to be a deficiency somewhere or other in the power of sustaining voluntary and involuntary exertion, and a tendency to aggravation or relapse on exhaustion. Did time permit, a study might be made from this point of view of other post-influenzal conditions, showing for instance how the peculiar catarrh of the liver is best treated by relieving the liver of work, in the shape of foods it cannot manage and of cholagogues it cannot endure; how the influenzal affection of the ocular muscles, which baffles the best-meant efforts of relief with lenses, yields speedily to darkness and disuse of vision; and lastly, how the mania and delusions of influenza are combated most hopefully by those remedies and means which, like opium, enforce sleep continuously for considerable periods of time.

# BACTERIOLOGICAL NOTES.

## THE RELATION OF BACILLUS COLI COMMUNIS TO TYPHOID FEVER.

In a paper presented to the American Public Health Association in Mexico, December, 1893, (*Modern Medicine*, III, 1894, p. 4), Kellogg gives a brief summary of recent investigations concerning the etiology of the colon bacillus after which some personal experiments are related.

It will be remembered that in 1887 Hueppe called attention to the possible pathological importance of the colon bacillus, having found this organism in nearly pure cultures in cases of cholerine. In 1889 Roded and Roux made extensive investigations of this bacillus in relation to typhoid fever in which the conclusion was reached that the typhoid germ is a modified colon bacillus. Several investigations have been recorded of outbreaks of typhoid fever resulting from the use of the water from a common source, usually a well, from which no typhoid bacillus could be found, but the colon bacteria were present in large numbers.

The claim that is made at present by certain bacteriologists is that the colon bacillus which ordinarily possesses very little pathogenic power can be made sufficiently virulent to produce an effect similar to that of the Eberth or typhoid bacillus.

Another interesting fact is the observation that the colon bacillus becomes increased in virulence during an attack of typhoid fever.

Vallet has shown that rabbits that were inoculated with the filtrate from vaults containing excreta from typhoid fever patients were protected to an appreciable degree against the inoculation of the typhoid bacillus. This experiment serves to explain the fact so often noted by sanitarians, that visitors to an infected locality are more likely to suffer from the disease than the residents who are accustomed to drink the contaminated water.

After certain experiments which are too lengthy to record in full, Kellogg draws the following interesting conclusions based upon his own work and the results of other investigations:

1. The bacillus coli and the bacillus of Eberth are so nearly identical in their biological characters that none of the numerous methods proposed for distinguishing them can be relied upon as giving constant results.

2. The bacillus coli gives in inoculation experiments identical pathological effects with those produced by the bacillus of Eberth.

3. The bacillus coli acquires, by passing through the body of an animal, biological characters closely resembling those of Eberth's bacillus. The bacillus coli found in vaults is much more virulent than the bacillus coli of the intestines or Eberth's bacillus.

4. The bacillus coli is much more resistant than the bacillus of Eberth, and thrives in vaults, while the bacillus of Eberth quickly dies under the same conditions.

5. The study of epidemics, and the bacteriological study of waters which have given rise to typhoid fever, lead to the conclusions that the bacillus coli at least shares with the bacillus of Eberth the property of producing typhoid fever under certain circumstances, and that the bacillus of Eberth may be only a variety or modified form of bacillus coli.

6. The contaminations of milk with the excreta of cows is a possible source of infection with the bacillus coli and with typhoid fever.

7. The same care ought to be observed in the protection of water used by cows kept for milking purposes from contamination with excreta, as for that used by human beings for drinking purposes.

8. Since vaults and cesspools constitute depots in which the comparatively innocuous bacillus coli acquires malignancy and virulence, rendering it highly destructive to human life, these convenient nuisances should be prohibited by law, and the destruction or disinfection by proper agents, or conveyance to a safe distance from human habitation, of all alvine discharges, should be compulsory as one of the most important means of conserving the public health."

---

UNKIND words can never be taken back.

## THE FLAGELLA ON THE TYPHOID AND COLON BACTERIA.

Moore (*Wilder Quarter-Century Book*, 1893) has described the molite appendages or flagella on three species of bacteria, viz., the bacillus of hog cholera, of typhoid fever and bacillus coli communis. A brief review of the literature on the method of demonstrating flagella on bacteria is given together with the author's modification of Loeffler's method. The flagella are carefully described. The point of special interest is the close resemblance that is found between the flagella of the three species but, perhaps, more particularly between the typhoid and colon bacteria.

The flagella are minute hair like appendages which radiate from the body of the bacillus. They vary in length and number. On the typhoid germs ten of these filaments was the maxium number found and on the colon bacillus seven was the greatest number. These varied in length from one to thirteen *microns* on the typhoid and from one to fifteen *microns* on the colon bacillus. They were from 0.1 to 0.2 *microns* in diameter when well stained.

These results differ from those obtained by Luksch, who found from 8 to 12 flagella on its typhoid bacillus and from 1 to 3 on the colon bacillus, a difference sufficiently great to be of differential value. Moore's results show that it is very difficult, if not impossible, to distinguish between these two species of bacteria by means of their flagella.

His conclusion is of considerable importance in showing that morphologically it is difficult to distinguish between these bacteria. It also shows the importance of the cultural characters of these bacteria in differentiating between them. In studying the flagella, the author endeavored to determine whether there was a difference in the flagella to correspond with the difference in the virulence or cultural characters of these bacteria, as they are often found to vary in these respects, when isolated from their apparently normal habitat. The conclusion reached was that there is no difference in the flagella to correspond with their functional variations. The author touches indirectly the question of fixing specific characters of bacteria or their functions. In these two species, for example, there is no doubt as to their specific differences, yet morphologically they are hardly distinguishable, but in their cultural or physiological properties they are easily differentiated. The little that is known about the structure of bacteria suggests the possibility that there are as yet unknown structural difference between bacteria which exhibit differences in their cultural or etiological properties.

## THE RELATIONS OF BACILLUS COLI COMMUNIS TO APPENDICITIS.

In the *New York Medical Journal* for December 30, 1893, Hodenpyl, has contributed an exceedingly interesting article on the etiology of appendicitis. The author summarizes the results of the bacteriological examinations of twenty-four cases of appendicitis and adds the results of many others. Of the thirty-five cases of which a bacteriological examination has been made the *B. coli communis* was the only germ isolated in thirty-two of them. In some cases colonies of these germs were found in the walls of the appendix. In one case a few colonies of the streptococcus developed in association with the bacillus. In one case the streptococcus were the only species of bacteria found. The streptococci found correspond in their biological characters with S. pyogenes. In one case *bacillus pyogenes foetidus* was found in addition to the colon bacillus.

Cultivations have been made from the contents of the intestinal tract and from the contents of several healthy appendices. In nearly every case *B. coli communis* appeared and frequently pure culture. In ten cases cultures were made from the peritoneum surrounding the appendix in people that died from different causes. Nine of them gave negative results.

The pathogenic power of *bacillus coli communis* is determined in two ways: (*a*) its occurrence in connection with lesions

unassociated with any other organism; and (*b*) the result of experiments on animals with this pure culture of the germs. It has been found presumably as the etiological factor in a large number of diseases. Among those may be mentioned general exudative peritonitis following perforation of the intestine, perirectal abscess, ulcerative colitis, suppurative inflammation of the gall-bladder, peritonitis following ulceration of the intestine without perforation, epidemic diarrhœa of children, endocarditis, meningitis, cystitis, arthritis and many other affections.

From his study of the colon bacillus and the results of other investigators, the author concludes this part of his paper with the following recapitulation:

1. "*Bacillus coli communis* is normally present in the intestinal canal after birth, but it is never found during life outside the intestinal canal in any of the other viscera, so far as is known, without being accompanied by lesions."

2. *Bacillus coli communis* has been found in the exudate in thirty-four out of thirty-five cases of exudative appendicitis, and in thirty-one of these it was found unassociated with other bacteria.

3. It has been found in connection with a variety of inflammatory and necrotic conditions other than appendicitis.

4. "Inoculations into animals of pure cultures of this bacillus result in inflammation, in the formations of abscesses, and sometimes produce general septic infection or intoxication."

## HYGIENE AND COSMETICS.

Hygiene is a science of modern times. It has grown from small beginnings until at present it is the most important part of a physician's study. The aim of hygiene is to find out the most favorable conditions of human life, as well as the means of preventing disease. If we speak of the hygiene of a single organ or a group of organs, it becomes a matter of determining the conditions under which this organ can attain its most suitable and complete cultivation, so as to be of the greatest use to the entire individual.

By cosmetics we understand those means by which mankind undertakes to make his body, or any of its organs, pleasing to the eye—that is, with the idea of being healthy and strong, on the one hand, and well formed and handsome on the other.

Any cosmetic which helps to improve and beautify an organ without injuring the health is helpful to gygiene. In other cases, however, although the desire to be beautiful is natural, the cosmetics used are injurious. Then the health suffers, and the cosmetic becomes a wicked enemy to hygiene. If one applies himself to a careful and scientific care of the skin, he must employ very important hygienic means. If one makes his head tender by continually wearing a covering which will not allow the air to come through, premature baldness will be the result. If one considers the normally built human foot beautiful and has a covering made reasonably suitable to its shape, he fulfills a very important hygienic condition for good walking. If one considers the pointed shoe handsome and forces his foot into it, this is a cosmetic, but by no means a hygienic measure. Crippled toes and corns are the result. We see, therefore, that hygiene and cosmetics stand in near relationship to each other, and should not be separated. Hygienic measures are dictated by reason; cosmetics by vanity. Naturally those hygienic measures will spread rapidly which serve the purpose of cosmetics, while hygiene is in a bad case when it must combat the temporary cause of injurious cosmetics.—Translated for *Public Opinion* from the German of Karl Rose, in the *Breslau Deutsche Revue.*

TERMS:—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 7, 1894.

## EDITORIAL.

### THE MEDICAL TREATMENT OF ANARCHISM.

There is a legend, redolent of antiquity, to the effect that a certain apoplectic and irascible citizen, self-made—the job of an apprentice—and of massive self esteem, once found his path occupied by an insignificant dog. Heeding nothing but his own convenience, the self-made, without due ceremony, proceeded to assist the animal to move aside. This injudicious action attracted the attention of the business end of the dog and resulted in a protest more effective than respectful. His dignity violated, the enraged apprentice's job roundly berated the owner for allowing such a vicious beast to be at large, and demanded the extermination forthwith of the dog that had bitten him.

"But," demurred the owner, "the dog is not mad."

"Mad," howled the infuriated egotist, "what in thunder has *he* got to be mad about? It's *me* that is mad."

This fable teaches whatever moral may be extracted from it, but it will serve to illustrate the emotional perturbation which led the *London Hospital* to evolve the following:

"That Anarchists, as a matter of fact are lunatics, is as obvious to common sense as that a dog is mad when he rushes at friends and foes indiscriminately, and with frantic teeth endeavors to tear them to pieces. The point of our question is this: Are European jurists prepared to pronounce Anarchists technically insane, and will Legistures enact statutes for their certification and restraint? The medical mind foresees an epidemic of Anarchism in the near future, and its natural instinct is to look about for preventive measures. The only preventive measures of any avail to avert severe epidemics of contagious diseases in cattle have been the killing of the infected cattle in the very earliest stages of the malady. In the case of human beings, the very early detection of cases and their prompt isolation have alone been efficient. Our first business is to secure the enactment of a statute or statutes declaring Anarchists and in-

citers to Anarchy "insane." When that has been done, competent investigators must be set to work to find out every possible British or foreign Anarchist or inciter to anarchy which our own country may harbor. These must then all be locked up in one or more criminal lunatic asylums, and there medically treated until such as are capable of cure are thoroughly cured; the remainder will be kept under restraint for life."

This suggestion to make, by legislative enactment, anarchism to be a disease and to prescribe a specific course for its treatment, might be regarded as a specimen of insular humor, were it not that the continued and atrocious crimes perpetrated by anarchists have forced a consideration of the subject upon every nation of the civilized world.

There is no doubt that some of these anarchistic outrages are perpetrated by individuals mentally unbalanced—some of them to such a degree as to be, in truth, irresponsible. But to attempt to prevent the spread of anarchism, and to expect finally to eradicate it by the enactment of repressive laws, the enforcement of which would require an inquisition of greater severity and unrighteousness than the Holy Office of barbarous Spain, would be very much like the effort of the old lady to restrain the Atlantic ocean by the vigorous use of her broom.

The proposition to officially declare anarchism to be insanity, and consequently irresponsibility, is not surprising in view of the apparent tendency of modern alienists to consider any variation from a standard assumed as the norm—which standard is remarkably inconstant—to be insanity. Insanity existing there can be no responsibility; the overt acts of irresponsible individuals cannot be held as crimes; the commission of crime is *prima facie* evidence of insanity, and therefore of irresponsibility, for the obvious reason that it necessitated a departure from the standard assumed as the normal. This may appear to be gross exaggeration, but it seems to be the foundation of the present style of reasoning in circles.

Whatever may be the responsibility of individual anarchists, it would be folly to assume that anarchism is *per se*, a degree of mental unsoundness sufficient to eliminate responsibility. Nor does a generalization from the manifestations of anarchism developed of recent years, justify the assumption of irresponsibility. The overt acts of anarchism, responsibility assumed —as it should be, are placed on the level of crime—where they belong, and are amply provided for, so far as punishment is concerned, by existing laws. Furthermore to declare anarchism, whatever that term may mean, to be insanity would ultimately result in reducing all crime to insanity, for anarchism would naturally include everything in opposition to order as it now is.

Anarchism exists. It is a problem that must and will be solved in the course of human development. But it is something more than a disease, physical or mental, and but a small portion of the subject lies within the domain of medical science, or is amenable to medical procedures for treatment.

What is anarachism? Theory, policy or conspiracy. Is it any or all of these?

That oracle of indigestion, Thomas Carlyle, once overheard a conservative Englishman, whose satisfaction with himself and his associations was complete, remark, in a very patronizing way to a more progressive man: "The British people, sir, can afford to laugh at theories." The wrathy philosopher, fixing the speaker with a glare, said, "Sir, the French nobility of a hundred years ago, said they could afford to laugh at theories. Then came a man who wrote a book called the 'Social Contract.' That man was Jean Jacques Rousseau, and his book was a theory and nothing but a theory. The

nobles could laugh at his theory, but their skins went to bind the second edition of his book."

Anarchism is something besides theory, and it would be base flattery to compare it with the French Revolution.

It can scarcely be said to be a policy, for, although claiming the purpose of reforming the present unsatisfactory conditions of life, unlike other reformatory movements which may appear akin to it—Socialism and Communism—it does not aim to provide any substitute for the conditions destroyed, nor to reconstruct any system of living from the materials of the fabric torn down.

Evidently a conspiracy, anarchism would seem to have some of the elements of a policy, and many of the characteristics of a theory.

It would be hard to furnish a definition of the term anarchism that would be at once accurate and comprehensive. It might be said to be total depravity. Perhaps it would be better defined by a provincial expression as pure on'ry fool-cussedness.'

As with the term electricity, we may arrive at the meaning of anarchism by a consideration of its manifestations and conditions. Thus, we find, invariably associated with anarchism, dirt, drink, disorder, degradation and debauchery. Undoubtedly environment is the most potent of predisposing causes, but there are others which are ever present and which relate particularly to the individual. For instance, that congenital or acquired 'constitutional tiredness,' which incapacitates the individual for effort; again a keen recognition of the desirability of utter abnegation—on the part of others; a sense of the injustice of urging the rights of any as against one's own, and other like conditions familiar to all. Among the exciting causes might be mentioned the cumulative effect of intoxicants; the exhaustion of credit at the bar of greedy capital; the unwarranted interference with individual desires or demands by the servile minions of a bloated plutocracy, acting by authority of unjust laws, whose evil design is to subordinate the individual's rights to those of the masses. In a word any failure on the part of creation to bring itself instantly into harmony with the present mood of the individual. Anarchism is a vicious kick against existence.

However conflex its nature, and however varied its manifestations, anarchism exists; will exist so long as do its causes; and will grow in direct proportion to the intensity of the conditions producing it. Neither direct repressive legislation, nor the construction of asylums to prevent its spread, or to accomplish its extinction, nor international measures for mutual protection, nor any agencies, physical or mental, will accomplish more than temporary mitigation of the evil so long as its causes persist unchanged.

Anarchism is an anomolous bye-product of civilization. It is an expression of natural law. It may be regarded as a retrograde metamorphosis. It is the desperate protest the less-fit against the extinction rendered inevitable by environments with which they are hopelessly out of harmony and which are surely if slowly accomplishing their destruction.

Anarchy finds its material in that class of humanity where the powers of resistance and insistance have failed to meet the demands made by the swiftly developing changes of modern civilization. Civilization itself, rather than the unfortunates who suffer because of inherent weakness, is responsible in large measure for the existence of the unhappy conditions, and it is within the power of the popular will to eliminate them. Merely to mention a few of the admitted causes of anarchism, which can be, and eventually must be changed, consider these facts. Mankind is fully aware that the progress of civilization is due to and depends upon the in-

crease of mental and moral power, which in turn, depends upon the increase in nerve power to resist the increase of pressure from environment, or a loss of balance would result which would be anarchy. And yet in place of making every effort to strengthen the nerve centres they are deliberately weakened by allowing and even encouraging the use and abuse of artificial stimulants, of unhealthy excitements, and of lethal narcotics. With accurate knowledge of the terribly evil consequences of concentrating individuals into very limited areas, the populations of great cities are allowed to grow denser and denser, until in the slums it is no uncommon thing to find a 10x12 cellar or attic furnishing a residence for two or three families of eight to fifteen individuals. Again the relations of capital and labor, and other similar problems of social and political economy. And under and pervading all, "Man's inhumanity to man."

Subject to the violent and unequal fluctuations of such stresses, human nature is to be developed, and there is little wonder for the existence and growth of that class of humanity among whom anarchism finds most favorable conditions for rapid and rank development. That expression of human nature which we term character, is a combination of the emotional, intellectual and moral elements of man. The emotional and intellectual phases are under the immediate direction of the will, as indeed is the moral element to a large extent. But the peculiar office of the spiritual is to inform and counsel in the exercise of the will power. The spiritual element of character, the most intangible, the most sensitive and yet the most important of man's nature, is the most difficult to maintain, and is the first to give way to inordinate stress. A marked feature of degeneracy is the lack of the sense of right and wrong—'moral imbecility' as it has been termed. From hence the descent to Avernus is easy.

With the constant and increasing output of defective classes, we are presented with the unique spectacle of society establishing and fostering products bound to act for the extermination of social order, and in place of preventing such products by destroying the services of production, wagging the head and seriously considering measures for eliminating its own workmanship. There is no need of wasting cerebral energy to discover some method by which one can both eat his cake and have it.

There is a remedy, a specific not only for the prevention, but for the cure of the evil; a remedy that has been known and proved for centuries. It is simple—so simple indeed, as to be quite overlooked by modern magicians and soothsayers. It requires no legislation to make it applicable; it does not infringe upon the rights of the individual nor of the public; it merely requires the actual practice of what is professed by the vast majority of anarchy producing nations. This remedy is the *spirit* of Christianity, with especial emphasis placed on that manifestation embodied in the two social laws: "Thou shalt love thy neighbor as thyself," and, "Whatsoever ye would that men should do to you, do ye even so to them." At once the simplest and most efficient, it is the only solution of the problem.

Until such time as this remedy will commend itself to the wise and prudent, all sorts of methods of treatment will be invented and experimented with, and fail.

Since anarchism has reached such proportions that it has become a matter of international consultation, we would respectfully suggest a plan that would seem to have some valuable features. It would certainly save expense in the long run; it would relieve the world of the feeling of terror that is now so widespread; and it would afford an opportunity to propagandists to demonstrate the righteousness of their professions, by means of a gigantic

object lesson which the world could observe without fear, and could study at leisure. Certainly it would be a much easier and quicker way to convince doubters and to obtain converts than are the eccentric and explosive arguments now in vogue.

Let the nations pool their issues, and set apart a desirable, but isolated territory, and then deport all adult, confirmed and irrepressable exponents of anarchistic vagaries, of both sexes. Carry them to this reservation and allow them work out their salvation without let or hindrance, the one restriction to absolute freedom being enforced residence in their peculiar locality.

**"Fracture of the Lower End of the Radius with forward Displacement of the Carpal Fragment."**

*Mr. Editor:*—I shall be greatly obliged if you will inform your readers that I am particularly anxious to know of any cases of Fracture of the Lower End of the Radius with Forward Displacement of the Carpal Fragment. Notes of cases, references to published reports, or information of specimens in museums will be of much interest to me.

Yours truly,

JOHN B. ROBERTS,
1627 Walnut Street, Phila.

---

A a meeting of the Philadelphia County Medical Society held March 28th, the following resolutions were adopted:

*Resolved,* That the Philadelphia County Medical Society has heard with great sorrow of the sudden death at Lebanon, in this State, of Dr. John Rauch, of Chicago, late Secretary of the Illinois State Board of Health; a man whose interest in the cause of Medical education and whose efforts in increasing the efficiency of the medical profession and maintaining its dignity and honor have rendered incalculable service to the public.

*Resolved,* That this resolution be published in the Journal of the American Medical Assocation and in the medical journals of Philadelphia.

T. B. SCHNEIDEMAN,
Secretary.

# ABSTRACTS.

## MEANS OF PREVENTING THE SPREAD OF CONSUMPTION.

### CIRCULAR OF PHILADELPHIA BOARD OF HEALTH.

All cases of tuberculous disease of the lungs (Consumption) taken origin directly or indirectly from other cases. This is now an established fact. Infection, however, is easily provided against if certain simple precautions are taken.

The chief modes of infection are:

First and Foremost—*By inhaling dry and pulverized expectoration.*

This is apt to occur when an ordinary pocket handkerchief is used by a tuberculous person for expectoration. When such a handkerchief is opened the dried expectoration is likely to be pulverized and diffused through the air. Thus it may be inhaled by others as well as by the patient himself, who is likely to suffer from drawing disease germs into portions of lung previously unaffected.

Another, and the most common source of pulverized expectoration, is the habit of spitting carelessly and indiscriminately, as on the floor or ground. The expectoration becomes dried and mixed with dust and then is easily carried into the air, and is breathed into the lungs or swallowed. The habit, therefore, is not merely offensive, but dangerous.

(2). *By using spoons, cups, and other articles* of the kind which have *not* been

*properly washed* after having been used by tuberculous persons.

(3). *By kissing.*

This source of infection is especially to be guarded against in the case of children.

*Self-infection* may occur, in addition to the ways mentioned, *by swallowing the expectoration.* The habit is likely to lead, sooner or latter, to infection of the intestines with tuberculous disease.

There are other modes of infection, as for example, by consuming the flesh and milk of animals having the disease. But this source is less common, and, as prolonged high temperature destroys the germ, if we cook our food (including milk) thoroughly, there will be no risk of becoming infected in this way.

Knowing the channels of infection we can easily take effective *precautions.*

(1). *The sputum must be destroyed and must not be allowed to become dry.* A spitting cup or flask containing just enough disinfectant solution to cover the bottom of the vessel should always be used for the expectoration. Out of doors a pocket spitting flask, such as Dettweiller's, should be employed.

In the house it would be well to use a pasteboard or paper cup, which should set in a china or metallic *holder. This cup with its contents should be burned at least once a day, but if the expectoration is considerable, much oftener.

Pieces of linen or calico about ten (10) inches square may also be carried. These should be used in case of absolute necessity only, and should be burnt as soon as possible afterward. No piece should be used more than once.

(2). Bed-rooms that have been occupied by tuberculous patients *should be thoroughly disinfected* before they are occupied by other persons, and a declaration or assurance on the point should always be demanded.

If the previous occupant of the room never allowed the furniture, hangings, or carpets of the room to be contaminated with the sputum there would be little need of this precaution. But as the people ordinarily of cleanly personal habits sometimes show a surprising amount of ignorance or carelessness in this respect, the following points should be insisted on:

(*a.*) Carpets, curtains and bed coverings should have been exposed to superheated steam under high pressure.

(*b.*) The floor and walls of the room should have been properly disinfected. Rubbing with new bread followed by the application of corrosive sublimate solution (a tablet of 7⅞ grains added to a pint of water) is probably the most effective practical method.

*There is no danger of infection from the mere breath* of a tuberculous patient. *The risk is from the dried expectoration.* Danger of social intercourse arises from the neglect of the precaution described.

Fresh air is of the highest importance for tuberculous persons. Hot and stuffy rooms have an evil influence over the disease. Except in special circumstances the bed-room window should be kept open by night as well as by day.

NOTE.—The disinfection of rooms that have been occupied by the tuberculous patients, and of beds, bedding, curtains, carpets, etc., will be promptly attended to upon a notice sent to the Health Officer, City Hall. The Board of Health has erected a most extensive and complete disinfecting plant for the disinfecting of such articles as have been mentioned, and upon notification will send for them and return them after thorough disinfection at a cost merely nominal.

*Cup and holder can be procured at the apothecaries. The paper cup can be easily made at home from the original sample.

**Toots from the Ram's Horn.**

PLEASURE may be bought, but happiness never.

STARTING for heaven on a gravestone is risky business.

Habit is first a servant, then a master, then a tyrant.

THE man who succeeds as a hypocrite has to devote his whole time to it.

SOMETIMES a single step in the wrong direction is equal to a mile.

No wound can be so deep as the one inflicted by a friend.

A PRESENT sometimes costs the recipient more than it costs anybody else.

ONE person's opinion is frequently based upon the exploded opinions of others.

A FEATHER from the dove's wing sometimes guides the arrow that pierces her breast.

## CHOLERA AND THE UNSANITARY CONDITION OF HAVRE.

Mr. Adolph Smith, the foreign correspondent, writes to the *Evening Telegraph* as follows:

In the autum of the year 1893 I wrote some letters from Havre describing the cholera epidemic which devastated that town. After Hamburg, of the large towns in Europe, Havre was the town which suffered most from cholera. It was to be hoped that severe lesson would have been turned to some advantage, and that the town would at once proceed to undertake works of a sanitary description. I am sorry to say that as yet nothing has been done; we have had words, and plenty of words, but no action. Chiefly through the instrumentality of M. David, the town architect, an Exhibition, of Hygiene was held at Havre last year. This served as an object lesson for the population, and in that sense was useful, for it showed how houses ought to be drained. Then a great deal of time was lost in making experiments with the Hermite system, but nothing more than discussions and experiments can be recorded. The town remains as unhealthy as it was before. Last year there were some more cases of cholera, and this year a small-pox epidemic is prevailing. The day before yesterday there were six cases of small-pox, and a short time ago there were as many as thirty-three cases of small-pox in a single day. The hospitals are more incumbered now tha they were during the great cholera epidemic; for though there have not been so many cases of small-pox as there were of cholera, the former disease is of much longer duration. A cholera patient often died in a few hours, or was cured in a few day, whereas a small-pox patient takes a month more to cure.

Nothing can be more disheartening than the sanitary condition of some of the streets at Havre. There are houses where it would be absolute murder to send any one to inhabit; yet nothing, it seems, can be done against these death traps. There is one house in particulor where almost every inhabitant dies of consumption. The air is so foul that even the robust soon become predisposed; and, as the whole house is impregnated with the germs of tuberculosis, the inhabitants cannot fail to contact the disease. In due course they die of phthisis, unless some other and more rapid disease sweeps them off beforehand. The Bureau d'Hygiene has rendered a great service in showing up these black spots. The institution has calculated the death-rate per street, and this on an average of ten years. We have before us, therefore, no accidental or exceptional figures, but a normal average, reckoned over a large number of years, and these figure, tell us that the worst street in Havre is the Rue de la Boucherie.

### A TALE OF DEATH.

This—the Butchers' Row—is appropriately named, only it is human beings and not cattle that are butchered. The average mortality of Havre amounts to the enormous figure of 30 9 per 1,000 per annum; but in the Rue de la Boucherie the mortality during the same time was equal to 55 1 per 1,000 per annum. In the ten years there had died out of every thousand inhabitants in this fatal street no less than 551 persons. Thus but for new arrivals the entire population would be swept away in less than twenty years. The same may be said of the Rue Francois-Mazeline, where out of 1,000 inhabitants 503 died in the ten years. The other especially bad streets are the Rue du College, 454; Rue de la Vallee, 454; Rue du Petit-Croissant, 449; and the Rue Albante, 411 deaths per 1,000 inhabitants in ten years. . .

There are besides thirteen streets where from 351 to 392 deaths occurred per 1,000 inhabitants in the ten years. Then we have sixteen streets where the number of deaths varied from 312 to 346 per 1,000 inhabitants in ten years. Finally there are twelve streets where the deaths numbered from 251 to 296 per 1,000 in the ten years. These latter twelve streets bring us down to an annual death rate of 21 1 to 20·6 per 1,000, which being below the average of the entire town, represents healthier quarters. In the Rue des Bouchcries, needless to say poverty, overcrowding, filth, ignorance, drunkenness, and wretchedness of every description, unite to kill off the population. There is especially a large proportion of Breton laborers, whose drunken and filthy habits are notorious. The streets where there is the

highest mortality are very narrow, the houses very high, and many of the rooms are never purified by a direct ray of sunshine. If we add to this the fact that there are no sewers, but all the filth flows into the street gutters, it may readily be imagined that deaths must result.

By the side of the general death-rate we have the death-rate from consumption, and we find that, roughly speaking, the deaths from phthisis are most numerous where the general death-rate is higest. Nevertheless. though this is correct, if we take groups of streets individually, it is the narrowest streets that have suffered most. Thus the Rue des Boucheries has 551 deaths and 81.1 death rates from phthisiss whereas the Rue du Petit-Croissant has 449 deaths and 122·9 death-rate from phthisis; but the former street is 8·67 metres wide and the latter is only 4·95 metres. In other cases, where the narrowness of the street does not seem to correspond so well with the number of deaths from phthisis, it will be found that the houses are expectionally high. Thus the street, though not actually is proportionately narrow. The condition of Havre, therefore, as ably demonstrated by the statisticians of the Bureau d'Hygiene, shows clearly that the want of pure air is one of the main predisposing causes of consumption. Of course this same cause increases the death-rate from other diseases, but it has a very terrrible bearing upon consumption.

## A CASE OF SIMULTANEOUS EXTRA AND INTRA-UTERINE PREGNANCY.

Dr. H. Gulzmiller (*Arch f. Gyn.*, Bd. 43, p. 223), reported the case of a patient, aged thirty-five, who had been pregnant four times, began with fifth pregnancy in May, 1890. As a result of some injury labor pains set in about Christmas, 1890, followed by discharge of blood. During ing Spring of 1891 a new attack of illness, particularly characterized by acute abdominal pains, together with the belief on the part of the patient, that the pregnancy had existed since the last twelve months, induced her to consult a physician. Prof. Courroisier made a diagnosis of extra uterine pregnancy with death of the fetus.

The fetus in the abdomen could be felt on the right side of the uterus. A sound passed into the uterine cavity showed it to be 8 cm. in length. Some days after this examination there was a discharge of blood and an increase of temperature. This rise in temperature was accepted as an indication of decomposition of the fetus; and on June 11, 1891 the operation was performed. A dead fetus of about eight months was found lying in the left tube. There was no decomposition of the amniotic sac. The child and the greater portion of the placenta were removed; the sac was stitched to the abdominal wall. On the following day, June 13, a three months fetus was expelled from the uterus. An uninterrupted recovery followed; all the remains of the placenta in the extra-uterine sac were expelled. A microscopical examination of the sac revealed that it was originally of tubul structure, which had become distended. The abortion of the intra uterine pregnancy was due to the introduction of the sound.

A collection of seventeen cases of simultaneous extra and intra-uterine pregnancy, found in the medical literature, were carefully reported, some of which consisted of twin pregnancy.

In closing the author enters into the careful examination of diagnosis, prognosis and treatment of these cases.—*Translated by M. B. Werner, M. D.*

### Snap Shots.

To be congenial it is by no means necessary that two persons should be alike in their dispositions or tastes.

There is something so imposing about a silent man that we hardly ever reflect that he very probably has nothing to say.

Whether or not a man is reliable depends frequently upon the persons with whom he is dealing.

The flea is the dog's best friend. It keeps him from being lazy and feeling lonesome.—*Florida Times-Union.*

[Stenographically Reported by C. C. Mapes, M. D.]

### DISCUSSION

Of papers o f Drs. Seiler, Curtin, and Watson, (See pages 457 and 490).

DR. JUDSON DALAND: Dr. Curtin's remarks with reference to the sweating sickness were of special interest to me, and one readily understands why the name was applied to this disease in olden times. His descriptions of epidemics that occurred long ago were well made.

Dr. Curtin's wide knowledge and extensive experience make anything that he says in regard to the therapy of this affection of great importance. With regard to the "grip-lung" to which he refers, this affection has for a number of years attracted my attention, particularly from a diagnostic point of view.

The physical signs in these cases often vary from day to day with extra-ordinary rapidity, in fact with such rapidity as to make one doubtful of the correctness of the first diagnosis. The pathological examinations show a mixed condition of bronchitis, catarrhal pneumonia, and collapse. These lesions occurring in different parts of both lungs, and varying with such extra-ordinary rapidity, suggests a distinctive nervous origin, and there is probably an interference with the nerve-supply of the lung.

I did not hear Dr. Curtin mention the use of strychnine and alcohol in the treatment of the general disease. The benefit derived from the use of these agents during the height of the disease is very great, and they are practically the chief remedies to be relied|on. The use of the salicylate of sodium and phenacetine has given me the results which he has mentioned.

Regarding the suggestion of Dr. Seiler that this affection be called American grip, I should say that although I have not studied European grip the descriptions which I have read, and the numerous conversations that I have had with Continental physicians, have failed to convince me of any essential difference in the disease as we see it here. I therefore think it unwise to add another to the various synonyms for influenza, which name the is one to be preferred.

Dr. Seiler also states that the chief cause of death is hemorrhage from the mucous membrane. In my experience the chief cause of death has been the pulmonary complication. With regard to the use of benzoate of sodium, I do not think that the favorable result described could be expected in many cases as seen in general practice.

With regard to the effect of quinine in the production of insanity and other mental disturbance in influenza, although I have seen many cases of influenza, most of which have received quinine, I have yet to see a case in which the causal relation between the mental condition and the use of quinine could be established.

DR. J. SOLIS COHEN being called upon by the President, said: I came here to listen, and have not prepared myself to take part in the discussion. I remember the inital papers of Dr. Glasgow and of Dr. Seiler very well, but while Dr. Glasgow named the disease "it," he distinctly stated that in his reading he could not find anything that resembled it except the old records of influenza. This was a very acute observation, made, as it was, three or four years before the epidemic became pronounced. My own earlier cases were treated exactly as Dr. Glasgow had recommended—that is, with benzoate of sodium, and I do not now know of any treatment that acts better than putting the patient at rest, giving benzoate of sodium in ten-grain doses every hour or few hours until the kidneys are acting freely, and then continuing it less frequently. Strychinine, acting as it does on the terminal nerve fibres, is of great service, for the disease exerts its baneful influence markedly on the terminal nerve fibers of the structures concerned in the nutritory and circulatory systems.

The class of cases that I have seen suggests that this disease is largely a disease of the lymph and circulatory systems. We know that the nasal lymphatics are in close connection with the sub-dural space, and in many of the cases where the nasal symptoms are severe, we have severe meningitis and those conditions which render the patient despondent, as a direct sequence by continuity of structure. The profound impression on the nutrition shows also that the lymph system is very much affected.

In the history of previous epidemics of this disease marked reference has been made to different varieties, such as the pulmonary, gastro-intestinal, and other forms of influenza,

and I have asked a number of my friends in general practice, whether they had observed in recent epidemics as many miscarriages as had been described in previous epidemics. I found that, with the exception of the epidemic of 1889-90, there had not been so many noted.

Another reason for regarding this as largely a disease of the lymphatic system is the occurrence of the affection of the throat described by Dr. Seiler: that peculiar puffy condition which looks apparently like œdema of the larynx and œdema of the palate. When you incise these parts, however, you do not get a serous fluid. Sometimes you have blood and sometimes a mucoid material, or lymph which may exude in long, continuous strands.

Now as regards the use of quinine in influenza, I have often been asked what can be done to prevent the occurrence of the disease in unaffected members of a family in which it has appeared. I have always advised the use of quinine in ten to fifteen grain dose early in the morning. I am satisfied that large doses often act as a preventive, and that in these cases the quinine does not so readily produce the ordinary symptoms of cinchonism.

In using strychnine I think that the best preparation is the arseniate, which I give in the granules dosimetriques of Burggraeve, containing one-half a milligramme, or about one hundred and twenty-fifth of a grain. The patient takes three to six or more granules a day, and continues it for a month or two. In that way many of the sequelæ can be prevented.

DR. FRANK WOODBURY: I look upon influenza as essentially an intoxication. In Europe epidemic influenza, or the grip, is now pretty well accepted as having for its cause the bacillus of Pfeiffer. It is stated that pure cultures of this bacillus will reproduce the disease in animals, thus fulfilling the requirements of a specific, infectious germ. Pfeiffer's bacillus, however, is like the tubercle bacillus often found in association with the staphylococcus and the streptococcus and other bacteria of suppuration, thus accounting for the organic inflammations. As the influenza bacillus is not found in the blood, it probably acts by its products principally upon the nervous system.

It is very possible that the germ of influenza may have suffered some modification in its development and pathogenic effects, owing to different climatic conditions in this country from those of Europe, so that we should not be surprised to find modifications in the course of the American disease, such as Dr. Seiler insists upon. That there is any etiological difference between the two kinds of epidemic influenza has not been suspected; possibly Dr. Seiler's observations may have been upon an entirely distinct disease.

The portal entrance of the poison into the system is worth considering. In most cases the culture ground of the bacillus is probably located in the upper air-passages, and I am inclined to think that the tonsils and naso-pharynx are the special points of election. In others the bronchial mucous membrane is most affected, while in other cases the gastro-intestinal canal is the particular place of development. It has occured to me that, just as in the administration of morphine hypodermatically, the effects of the drug are most marked if injected in the neighborhood of the seat of the pain, although we know that the drug acts through the general circulation, in a similar way the well recognized varieties of influenza may be connected with the several culture-fields of the bacillus, the toxine acting most virulently in its immediate neighborhood, producing cerebral, gastro-intestinal, or broncho-pulmonary phenomena, which have been alluded to.

This leads me to speak of the prophylaxis of influenza. I can indorse what Dr. Cohen has said with reference to quinine. I employ it as much for antiseptic and prophylactic purposes as for its tonic effects. The mouth and throat should be kept clean by the use of mild antiseptics, and the naso-pharynx by the use of Seiler pastilles or Dobell's solution, and the throat carefully watched. There is no question in my mind that the disease is contagious; when it appears in one member of the family others are liable to be affected. This has been established by the local epidemic which was reported by Drs. J. Wm. White and Simes to this Society several years ago. It will be remembered as the case of Dr. S. S. White, who died of influenza in Paris, and whose body was brought to his home in this city, whereupon a number of persons who were in the room when the casket was opened contracted the disease although there were no other cases in the city at the time.

In the few cases where I have used benzoate of soda, I have been pleased with the result. I have especially relied on strychnine, given in the acid solution of the hypophosphites according to the formula of Dr. Gerhard. The strychnine is given in doses of 1-32 of a grain, gradually increased. With this I have used cocoa, and in regulating the diet I have found the juice of fresh fruits, such as the orange and pineapple, to be of service in assisting the weakened digestion. These juices have been shown to have considerable peptonizing power over albuminoids, and the salts they contain possess diuretic and antiscorbutic effects which are useful in improving the condition of the blood.

DR. WILLIAM S. STEWART: There is a great variety in the manifestations of influenza, but the ordinary influenza which is so common in this country, is certainly very contagious. The influenza of la grippe is a different affection from the ordinary influenza. I do not think that it is particularly contagious. I have seen grave and serious cases where no other member of the family was affected.

In regard to treatment, I wish to say a word as to the bromides, particularly in those cerebral cases that would be affected by quinine. I have combined the bromides with gelsemium with great benefit. In some of these cases, if you give quinine you only intensify the pain and delirium. When the cerebral suffering is relieved then it is important to give iron, quinine, and strychnine, and it may be aromatic spirit of ammonia, to tone up the system and to overcome the heart-depressing effect of the disease.

DR. COHEN: I am pleased to note that Dr. Curtin and Dr. Watson in some of their conclusions confirm those which I published in an article upon "Catarrhal Fever," contributed to the MEDICAL AND SURGICAL REPORTER, October 29, 1887, some time previous, therefore, to the enlarged experience which we now have. One point which I endeavored to make was that influenza is always with us, but that except in times of widespread epidemics it was only recognized as such by those who, through teaching or early experience, had had their attention specially directed to it. This is, I think, an important matter and will bear emphasizing.

I am also glad to note that experience has confirmed the usefulness of the salicylates in this disease. In the cases which came under my observation in 1885, 1886, and 1887, and upon which the paper referred to was based, I had found cinchonidine salicylate apparently curative, and so reported. I have more recently used sodium benzoate in early cases with much benefit, especially those in which there was a tendency to suppression or great diminution of urine or which exhibited severe pains in the loins.

The value of strychnine in the prevention and treatment of the distressing sequelæ cannot be overestimated. The drug should be given in small doses frequently repeated.

Drs. Curtin and Watson emphasize the great sweating; I have been much impressed with this in my own experience. I remember one case in an old man, in 1889, in which profuse sweating and subnormal temperature were the only objective symptoms of the disease. This continued for two weeks, and I am satisfied that if that patient had not been put to bed and kept there with the external application of heat and with the administration of hot drinks, of cocaine, and restoratives, he would have died, almost without realizing that he was sick. He had complained merely of discomfort in the throat, nothing to account for the symptom being discernible on examination.

DR. SAMUEL WOLFE: I have observed a considerable number of cases of the intestinal form in which the symptoms resembled those of dysentery, but the affection yielded to the same treatment as did other forms of grip. The affection of the nervous system is a very large element in the disease, both in its onset and its sequelæ. The variability of the seat of attack shows this to be the case. The sequelæ—insanity, meningitis, and neuritis—point to a secondary poison affecting the nervous system. Many chronic nervous affections date back to an attack of grippe.

Influenza is comparable to diphtheria inasmuch as we have the acute symptoms due to primary poisoning and the secondary symptoms due to poisons generated during the disease.

I would take exception to the statement that influenza is similar to the ordinary colds which we always have with us. The best treatment for an ordinary cold is trying to shake it off; this in influenza would lead to prolonged convalescence or sequelæ. The most valuable element in the treatment of influenza is rest. The patient can do better without any drug than without rest. This rest should be prolonged until the patient can make efforts without tire. This difference alone proves that influenza is dissimilar to an ordinary cold.

As to therapeutics, I believe that quinine is one of the best remedies, not in one large dose, but in smaller doses frequently repeated (4 grains every two hours) until some cinchonism is produced, and this should be brought about in the early part of the day. I would rather do without any other drug than give up quinine. In the intestinal form, salol is a valuable remedy, and may be combined with quinine. The neuritis is to be treated like other forms of neuritis. Hypodermatic injections of cocaine (in doses of from one-eight to one-half grain) near the seat of pain, and repeated twice in the twenty-four hours, relieves the pain not only for a short time but permanently, and brings about an earlier convalescence.

DR. COHEN: Replying to Dr. Wolfe, I did not mean to say, and I trust I did not say, that influenza is the same as in ordinary cold, but I wish to emphasize the fact that influenza is not merely an epidemic disease, that it is seen every year and every month, and that many cases of influenza are ordinarily mistaken for "colds," for acute catarrhs of nose, throat, bronchi, stomach, or intestines, and even in some instances for typhoid fever and for rheumatism. Influenza is at

times the easiest and at other times the most difficult disease to recognize. The opinion of those who have most closely studied the affection is that it is a disease of intoxication, due to a specific poison, depressing the organic nervous system. This poison may be the result of the development of a microbe, but as yet this microbe has not been definitely proved to exist. In consequence of the organic nervous depression we have, for example, labored respiration from pneumogastric failure even when the lung cannot be shown to be much involved. The general depression and the severity of symptoms not to be accounted for by signs discoverable upon physical examination, differentiate the disease from ordinary "colds." Besides this disproportion of symptoms to signs, there are a number of minor points—for example, general soreness or aching, or localized pain, such as infra-orbital or supra-orbital neuralgia, and the neurotic character of many symptoms such as dyspnœa and cough, and cutaneous hyperæsthesia. The general course of the affection is likewise significant. It is rarely confined to a single physiologic apparatus, but beginning as a coryza or a tonsillitis may end as a diarrhœa, or beginning with gastric symptoms terminate as a broncho-pneumonia or a laryngitis.

When the true nature of cases is not recognized and they are allowed to go untreated, or rest is not part of the treatment, serious sequelæ are often developed. It was the observation of such sequelæ, and especially of chronic broncho-pneumonia in children attending the Medical Dispensary of the Jefferson Medical College Hospital during my early years of service there, that first impressed me with the facts recorded.

DR. SEILER: The diversity of opinion as to symptoms and treatment lies in the fact that we indiscriminately speak of grip, influenza, and la grippe. We also speak of fever and catarrhal pneumonia. High temperature does not constitute fever. The disease consists of infiltration of the mucous membranes as a result of an intoxication. In American grip, the benzoate of soda is the best remedy. In influenza, quinine is of service. The treatment of the sequelæ is to be guided by their character.

DR. CURTIN: As to the effect of quinine, as stated by Dr. Seiler, I recall three cases of insanity following influenzal attacks, which occurred before any treatment was instituted.

DR. WATSON: It may be that Dr. Seiler has in mind catarrhal fever. In that affection there may be low temperature, moist tongue, and all of the symptoms which he has described.

As to antidotes, I have used benzoate of sodium in many cases, but did not get any better results than from other remedies, as salicin and the salicylates. I have seen five cases of insanity following influenza where quinine was not used, and many cases persistently using it which did not become insane. This should be distinctly stated lest Dr. Seiler's experience should be understood to be the usual one.

---

**Pental an Excellent Anæsthetic.**

P. F. Feodoroff has experimented with pental in general surgical anæsthesia. This very stable substance does not become decomposed either in light or air; its specific gravity is about that of ether, and, like this latter, it is very volatile. Care must be taken to keep this substance removed from the fire; it burns with a very bright flame, but it has no explosive properties. The vapor of pental does not irritate the mucous membrane. According to Feodoroff, the duration of pentalization is from one to two minutes, and, the condition of anæsthesia once induced, it may be prolonged from two to five minutes. In about 50 per cent. of the cases the radial pulse is not modified, but otherwise the pulsations become more frequent, and sometimes there is arhythmia. It is principally during the first minute that disturbances of the circulation shows themselves; it is therefore, very necessary to be circumspect during the primary inhalations, and not to have recourse to the concentrated vapor of pental, except after the first minute, when the action of the heart will already be regularized. It is important to call attention to two peculiar effects of the drug: 1. Analgesia occurs while consciousness is still retained; the patient executes all the orders of the physician, feels the contact of the instrument, but does not feel pain. It would, however, be imprudent to operate before the complete loss of consciousness; the majority of accidents which have happened during the use of pental were due to reflexes occurring in subjects insufficiently anæsthetized. 2. From ten to fifteen minutes after a first adminstration of the drug it may again be used without its action being weakened; it would even appear that the subjects are still more susceptible to its effect. One must also be careful never to operate with a patient in a sitting posture, but always in the recumbent position, for fear of dangerous accidents. To resume: Pental is an excellent anæsthetic in operations of short duration.—(From *Univ. Med. Journal*).

---

A METHODICAL man died in Berlin recently, at the age of seventy-three. When eighteen years old old he began keeping a record, which he continued for fifty-two years, which is the best commentary we have seen on the life of a mere worlding. His life was not consecrated to a high ideal. The book shows that in fifty-two years this "natural man" had smoked 628,715 cigars, of which he had received 43,682 as presents, while for the remaing 586,021 he had paid about $10,433. In fifty-two years, according to his bookkeeping, he had drunk 28,786 glasses of beer and 36,085 glasses of spirits, for all of which he had spent $5,340. The diary closes with these words: "I have tried all things, I have seen many, I have accomplished nothing."

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

THE ANNALS OF GYNÆCOLOGY AND PÆDIATRY

for March. Dr. J. F. W. Ross contributes a paper on

**Influences Affecting the Results in Abdominal Operations.**

He considers the subject under four heads: 1. The influences inherent in the patient. 2. The influences closely connected with the character of the operation. 3. The influences due to the atmosphere and surroundings of the place in which the operation is performed; and 4. The influences brought to bear upon the patient by the details of the after-treatment. In regard to the first of these heads, he thinks that while pus in wounds that have been made under aseptic or antiseptic precautions may at times be due to the conditions of the air or some carelessness on the part of the operator, it also may be due to some condition inherent in the patient. Conditions of the patient affecting the result of abdominal operations or of any operation, are scroffula, anæmia, malarial poisoning from bad drainage and impure drinking water, and perhaps a condition produced from eating improper or insufficient food. In such cases the system is unable to provide the proper barrier against infection, and, as a consequence, the wound does not heal kindly, and the patient does not do well from the very first. The presence of the tendency to bleed may seriously affect the results of the operation, as may also any organic disease in other viscera. The author dreads operations on patients suffering from renal disease more than in cases of heart disease. If the renal disease is sufficient to produce an œdema of the tissues the wound does not heal as kindly as it otherwise would do. The mental condition of the patient may also affect the result and the author reports a case in point in which the operation for the removal of a simple ovarian cyst was followed by an acute mania, due to fright. She died on the eighteenth day after operation. In this case it is interesting to note that the patient's brother was burned some years previously and that when the burn had healed he became maniacal and died insane.

In regard to the influences due to the atmosphere and surroundings of the place in which the operation is done, the author is of the opinion that we have been taught to pin too much faith to antiseptics and that we should learn to look further and pay greater attention to other matters than we do. He would not, however, discard antiseptics. He has found that "when the peritoneum has been opened in a contaminated atmosphere and closed again, the antiseptics prevent wound-contamination and assist the wound to heal kindly, but the poison introduced into the peritoneum at the time of operation is sufficient to produce irritation with a little more distention than one cares to see, with a little higher temperature and pulse than one cares to see, and, though the patient recovers, the progress of recovery is not as free from incident as it ought to be." He is satisfied, also, from his own observations that the entrance of a septic case into a building in which abdominal operations are being done on the same floor or the floor above, has an influence for evil on the results. When a patient dies from peritonitis after the removal of a simple ovarian tumor, where there can be no infection from within owing to the nature of the disease, he considers it of the greatest importance to criticise carefully the surroundings of the patient at the time of operation. He raises the interesting question of how far the fact of the operator having past through an attack of contagious influenza just previous to the operation affects the result. He also thinks that cases operated on in isolated houses among the mindle class, when the house has been put in thorough order before the operation, and when a trained nurse has been employed, have done better than any others. Each house thus becomes a little private hospital with one bed.

As to the influences brought to bear on the patient by the details of the after-treatment, the author is of the opinion that "a drainage-tube should be used after separation of many adhesions, and after washing out the abdomen for the removal of peritoneal fluid or septic material. When used for the detection of hemorrhage it should be removed in a few hours; when used after washing out the peritoneal fluid or septic material it should be used for a few days, and when removed a rubber drainage-tube should be passed through its centre, and left *in situ* for a few days longer, so that any subsequent collection of pus may readily find a track through which to burrow to the surface. When hysterectomy is performed by the extra-peritoneal method, and there have been many a adhesions to contend with, a drainage-tube should be used for a few hours above the stump. When hysterectomy is performed by the abdomino-vaginal method a drainage-tube should be passed into the *cul-de-sac* of Douglas from the front, even though the vagina be packed with iodoform gauze. The tissue around the cervix has a tendency to ooze, and enough blood may lodge in the *cul-de-sac* of Douglas to set up a fatal peritonitis."

The author condemns the use of so-called capillary drainage, produced by packing the glass-tube with iodoform gauze, and considers the practice a dangerous innovation. Where the drainage tube is used to detect hemorrhage, its usefulness is lost when packed with gauze. To check the hemorrhage it is necessary that the pelvis be kept dry. While blood-clot may be left in the pelvis with safety in some cases this does not apply to pus cases, where the blood is readily infected.

He has also come to the conclusion that peritoneal fluid is very apt to become infected,

and when peritoneal fluid is present in any quantity at the time of operation, as in cases of papilloma of the ovaries or tubercular peritonitis, it is better to wash out and drain the cavity than to draw off the fluid and close the cavity; the water thus takes the place of the peritoneal fluid, and, owing to its chemical composition, is not as apt to become inflected. The large quantity of albumen found in the peritoneal fluid in these cases must make it an admirable culture medium.

He does not place much reliance on the efficacy of purgatives for the relief of peritonitis following abdominal operations and thsnks that they are not of the value that many authors would have us believe. It is better not to operate at all than to do an incomplete operation for the relief of pus-tubes or suppurating ovaries.

Dr. Charles P. Noble discusses

**Profuse Menstruation.**

The following are the conclusions arrived at by the author:

1. Menorrhagia in young virgins is usually functional, due to disturbances in the vasomotor nervous system, or to relaxation of the tissues; in general caused by the rapid growth which at times takes place about the time of puberty. Because of its pathology, menorrhagia in young virgins is usually curable by general treatment.

2. Menorrhagia occuring in young childbearing women is usually due to some mishap in connection with pregnancy or parturition, such as the retention of products of conception, lacertion of the cervix or perineum retro-displacement of the uterus, subinvolution, inflammation of the uterine appendages, and pelvic congestion. Menorrhagia in this class of women is curable. It usually requires local treatment of an operative nature. When due to subinvolution and malpositions of the womb, operation is unnecessary.

3. Menorrhagia in women approaching the forties and in those who are older is usually due to gross diseases of the uterus, such as fibroid tumors, polypi, adenoma, or malignant tumors. Menorrhagia occurring in this class of women, except when due to advanced malignant disease, is curable, but almost invariably requires operative treatment applicable to the disease present in the particular case.

4. As menorrhagia is a symptom and not a disease, an exact diagnosis is requisite in every case. With the exception of young virgins it is desirable that a physical examination of the pelvic organs be promptly made. The importance of this examination is the greater with the increasing age of the patient. Special considerations should influence the practitioner to postpone the local examination in the unmarried unless it be reasonably certain from the symptoms that gross local disease is present.

5. There is no treatment for menorrhagia *per se*. By general measures, such as rest in bed and the use of digitalis, strychnine, and ergotine, pelvic congestion can be lessened, and in that way menorrhagia can be, at least in part, controlled; but it cannot be too strongly insisted upon that in every case of menorrhagia an exact diagnosis must be made and the oppropriate treatment addressed to the disease which is present.

The same author also describes "A New Uterine Curetting Forceps" and "The Perfect Needle Holder." Cuts of these instruments are given.

Dr. J. Adrian Goggans discusses the

**The Treatment of Chronic Diseases of the Uterine Appendages.**

Endometritis he regards as the most serious of the diseases peculiar to women from its consequences. He treats these cases by rest, vaginal irrigations, sitz baths, and in some cases ergot and hydrastis. Locally, he applies every fourth or fifth day some mild cauterizing agent, and generally prefers a solution of iodized phenol in glycerine, to the entire uterine mucous membrane either with or without previous dilatation, and follows this up with tampons of cotton (saturated with boroglycerine) in sufficient quantity to elevate the uterus. The principal signs which indicate that an operation should be performed are:

1. Those attending pelvic peritonitis, accompanied by tortuous and distended tubes, which may usually be felt in Douglas' pouch behind the uterus. This condition may be preceded by the history and symptoms of an abortion, a gonorrhœa, or a tubal pregnancy.

2. The physical signs of large and tender ovaries due to chronic abscess.

3. The physical signs of prolapsed and tender ovaries, accompanied by irregular hemorrhages, and incapaciting pains.

4. Some few cases where dysmenorrhœa is the principal symptom, with a probability of its being kept up by chronic disease of the ovaries and tubes.

5. Where hemorrhage is the principal symptom, accompanied by the ordinary signs of grave pelvic disease.

6. In a few cases of general peritonitis preceded by the symptoms of rupture of a pre-existing abscess, ovarian abscess, pyosalpinx, or abscess in the appendages developed during the progress of puerperal septicæmia.

Dr. R. S. Sutton, in a paper on "The Treatment of the Pedicle in Hysterectomy," says he is in doubt if any method can be uniformly depended on, yet every case should be considered on its own merits. The elastic ligature or the wire serre-nœud is a good method if the patient is not too fat, and amateur operators will do well to begin with it.

John G. Kerr, M. D., of Canton, China, contributes a translation of "The Tat Shang Pin, or Midwifery made Easy" a popular work on midwifery among the Chinese, in common use among the people, and the standard authority in all difficulty cases.

In the department of pædiatry is the report of the proceedings of the Section on Pædiatrics of the New York Academy of Medicine. Dr. William P. Northaup presented a paper on "Scorbutus in Infancy" a review of which has been published in the issue of THE MEDICAL AND SURGICAL REPORTER for March 31st, 1894, page 476.

THE VIRGINIA MEDICAL MONTHLY

for March contains a paper by Dr. I. S. Stone on

**The Importance of Early Diagnosis of Cancer of the Uterus.**

The author thinks that the uterus should not be removed save when the disease is confined to the cervix. If the disease has extended to the body of the uterus, it may be taken for granted that it has extended elsewhere, and cannot be entirely removed, in which case, thorough curretting and actual or chemical cauterization afford not only relief from pain, hemorrhage, etc., but probably prolong life as much as the more dangerous extirpation. The author urges that some effort should be made to arouse the general practitioner to an appreciation of the importance of watching patients more closely in order that the cases should be dealt with before they become hopeless.

**Membranous Croup.**

is discussed by Dr. John Dunn. The author believes that croupous laryngitis and laryngeal diphtheria are two separate and distinct diseases. The great difficulty of curing this disease lies not so much in the nature of the disease itself as in the region it has chosen to manifest itself. When the case is seen early, before the membrane threatens the closure of the larynx, the author advocates the administration of three or four grains of calomel with a quarter of a grain of ipecac and five grains of bicarbonate of soda, to be followed after four hours by a dose of castor oil. Pilocarpin may be given, provided the patient is robust and the case seen early enough. The usual expectorants and emetics should be avoided after the formation of the membrane, and the author sees little use for them at any stage of the disease. The writer advocates a warm, moist atmosphere for the room, believing it favorable to the casting off of the membrane. He also advises the impregnation of the air of the room with tar, which may be done by putting a table-spoonful of the ordinary commercial tar in half a pint of water and letting the steam from this pass into the room.

Tracheotomy should not be deferred till the patient is in the arms of death. The author favors the low operation, when it is possible, for the reason that the lower opening of the tracheal canula is then below the line of the membranous deposit.

Dr. W. E. Fitch, contributes a paper on

**Summer Complaint.**

The treatment, according to the author, should be conducted on the following lines: First. The child's strength must be sustained, and in all efforts to cure the diseace, its general welfare must at all times be closely watched; nor must its frality be overlooked. Second. Removal of intestinal contents. Third. Regulation of diet. Fourth. Administration of intestinal antiseptics. Fifth. Combating special symptoms. Under no circumstances should the natural diarrhœal discharges be trusted for the removal of the intestinal contents. The author advocates the use of calomel in one grain doses, every four hours, followed by a dose of castor oil. For children under one year, he makes the dose of calomel one-half grain. After the bowels are freely moved, the number of stools will generally grow less; but the persistance of dangerous nervous symptoms should invariably lead to a suspicion of retention of poisonous feces. The author finds it difficult to get the mothers to withold food from the child for a sufficient time to enable the poisonous material to be thrown off, therefore, he has given up the practice. When the stools are putrid, with an intensified fecal odor, it indicates the decomposition of proteid material. No other kinds of food can give rise to putrid odor except the albumins. In such case it is clear that the albumins should be withheld. While proteid food is withheld, one or more of the carbohydrates may be given. Of these arrow-root is theoretically the best; but the author has found that fresh soda crackers answer the purpose better. Rice may be allowed but children seldom like it. He has often allowed a baked potato without ever regretting it. Sterilized milk he regards as useful in the prophylaxis of summer compaint but not its cure.

Acid-smelling stools are due to the fermentation of the sugars and starches, but if you withhold all carbohydrates and put the child on cow's or breast milk, you will set up a putrid form of the diarrhœa, and transform a comparatively harmless form of the disorder into a harmful one. In mild cases you can still allow carbohydrates in small quantities: but if the case is severe and the child weak, withhold all carbohydrates for twenty-four hours, or until the tenesmus and tormania subside. On returning to food, milk alone should be allowed, as the carbohydrate which it contains (milk-sugar) is the least liable of any to continue the disturbances.

Whatever food is given in summer complaint should be carefully regulated qualitatively, and should be given in small quantities at regular intervals of considerable duration. Just enough food to maintain the child's strength is all that should be allowed. If the child is wet-nursed it should only have the breast at regular intervals—about every four hours.

The author has never had any success with lavage of the bowel. The author has frequently used the following prescription with success:

℞ Bismuthi subnitrat..... ʒiij
Pepsin saccharat..... ʒiss
Salol..... ʒj

M.—Make charts No. 12. —Sig. One before or after each feeding or nursing to child of ten to fourteen months old.

Opium is a drug much used and abused in this disease. In the acid form of the disease, while systemic poisoning is not present and where there is much pain and tenesmus, opium is indicated. Here the deodorized tincture is preferable, administered in chalk mixture with subnitrate of bismuth, which also has an astringent action. Still, however,

the pain may be assuaged by heat, and the bowel movements controlled alone by bismuth, while the use of opium is *entirely* dispensed with.

Dr. I. S. Stone reports a "Series of Twenty-five Abdominal Sections" with three deaths —one from shock, one from general peritonitis, and the other from sepsis and the pressure of a large tumor. The author states that he has never yet found an ovarian cyst in a negress.

Dr. N. L. Guice reports a case of

**Masturbation in a Female Child Eleven Months Old.**

The fingers of the right hand were firmly placed upon the vulva and the left leg brought across the right in position to increase the pressure, and was thus held in a condition of rigidity. Thus the child lay upon the back with the entire voluntary muscular system in a condition of tonic rigidity, the eyes closed and face and lips distorted. The fact that pleasure was experienced by the little victim was clearly evident; and when caused to desist, she would cry vigorously. Let alone, she would at once resume the practice, taking always precisely the same position.

Upon examination, the vulva was found to be normal, excepting the clitoris and minor labia, which were somewhat enlarged. Titillation of the clitoris would promptly bring about the muscular rigidity and other evidences of enjoyment, as exhibited when the child herself was masturbating.

The practice had probably been inaugurated by a colored nurse in order to secure quietude of the child. To break up the practice, the right hand was secured in a sling about the neck, and the thighs separated by means of a stick attached to either limb above the knee, to prevent approximation of the thighs. Added to this, the child was kept as much as possible in the arms of the mother when awake.

Dr. Hunter McGuire reports a case of "Tuberculosis of the Bladder" and advocates supra-pubic drainage of the bladder and rest, in the treatment.

Other papers in this issue are:

"Diseases of the Skin," by James C. McGuire, A. M., M. D.

"The Care and Treatment of the Insane in Private Practice," by J. T. Wilson, M. D.

"Some Nervous Effects of Digestive Disorder," by A. K. Bond, M. D.

"Ovarian Cyst — Laparotomy—Prolonged Delirium, etc.---Recovery," by R. S. Martin, M. D.

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## MEDICINE.

### Puerperal Sepsis; Its Prophylaxis and Treatment.

Dr. Robert A. Murray, read a paper with this title. Antisepsis during labor, he said, was believed to be as necessary as in surgery. Three antiseptics could be managed easily—corrosive sublimate, carbolic acid and creolin. The prophylaxis should begin with a bath and a change of clothing. The vulva especially should be cleansed carefully. A new rubber cloth should be spread over a clean sheet, and over the rubber there should be a draw-sheet. The importance of an enema should not be forgotten. A vaginal injection of a 1-to-3,000 solution of corrosive sublimate or of a two-per-cent solution of creolin should be given before labor, but usually not after it. Creolin was to be preferred to corrosive sublimate, because it was something of a lubricant, while corrosive sublimate was distinctly astringent, and so facilitated laceration. An antiseptic pad and napkin should be applied, and never removed except for examination, which should not be more frequent than was actually necessary. The physician's hand should be scrubbed thoroughly and immersed in a 1-to-2,000 solution of corrosive sublimate or a two-per-cent. solution of creolin. The antiseptic pad should be applied again after the birth of the child and before the expulsion of the placenta. Retained membranes and pieces of placenta should be removed at once by the aseptic hand, and then an intra-uterine douche should be given. Fluid extract of ergot, in half-drachm or drachm doses, was to be recommended in the majority of cases. After urination an antiseptic solution should be applied. When there was a bad odor to the discharge a vaginal douche was to be ordered, but if the remaining finger showed that the foul discharge came from the uterus, it must be thoroughly curetted and a single intra-uterine douche given. In prolonged cases instruments were to be employed. The nurse should never be allowed to examine a patient. In case of sepis, the same general plan of antisepsis should be followed, but the vagina ought to be inspected so that the diphtheritic membrane might not be carried into the uterus.—*N. Y. Med. Jour.*

### The Use of Chloroform in Gynecology and Obstetrics.

Brennecke (*Munchener Med. Wochenschrift*) reaches a different conclusion from many observers with regard to the action of chloroform on the kidneys. He calls attention to the fact that where the patient has no bad symptoms after anæsthesia, albumin is invar-

ably absent from the urine, and *vice versa*. Serious renal troubles may develop after the administration of chloroform in patients who showed no previous evidences of the same. Albumin in casts (nearly always hyaline) usually disappears from the urine within a few days, coincident with the disappearance of unfavorable general symptoms, such as nausea, loss of appetite, etc.

The writer concludes that chloroform should be administered only when it seems to be absolutely necessary, and that it is contra-indicated in cases of renal disease. With the exception of fatty degeneration, he thinks that its use is attended with less danger in organic cardiac than in renal affections. He furthermore advises that its use in midwifery be limited, and that it be excluded in the treatment of eclampsia(?)—*American Journal of Medical Science.*

---

### Dry, Scaly Conditions of the Epidermis.

Dr. Gordon Sharp (Leeds), for the prevention and treatment of chapped hands, and as an antiseptic and deodorizer for the hands advises:

℞ Spirit of camphor,
Spirit of nitrous ether,
Strong acetic acid, of each, 1 part.
Mix and add glycerin, 13 parts.

Wash the parts with warm water; dry, and rub in the liniment at bed-time. The application dries in a few minutes. It may be applied again in the morning, and washed off in a few minutes. Owing to the production of acetic ether, the application has an agreeable odor.—*British Medical Journal.*

---

### Diphtheria.

As a local remedy, MM. Knopf and Levy, of Strassburg, employ:

℞ Papayotin .....3iiss.
Liquefied carbolic acid.....3i¼
Water.....q. s. ad 3iij—M.

The throat is painted with the above mixture every ten minutes during the first two hours. Subsequently it is used once every second hour.—*La Med. Mod.*

---

### Ten Tests for Death.

An English physician writes to the London *Lancet* that he was called to see an old lady who was believed to be dead, but whose countenance looked natural and life-like, the eyes being open. The family, being extremely anxious, urged that all the tests of death be applied, and this was done in the following order:

1. Heart sounds and motion entirely absent, together with all pulse movement.
2. Respiratory sounds and movements absent.
3. Temperature of the body taken from the mouth the same as that of the surrounding air in the room, 62° F.
4. A bright needle plunged into the body of the biceps muscle (Cloquet's needle test) and left there, showed on withdrawal no sign of oxidation.
5. Intermittent shocks of electricity at different tensions, passed into various muscles and groups of muscles, gave no indication whatever of irritability.
6. The fillet test applied to the veins of the arm (Richardson's test) caused no filling of the veins on the distal side of the fillet.
7. The opening of a vein to ascertain whether the blood had undergone coagulation, showed that the blood was still fluid.
8. The subcutaneous injection of ammonia (Monte Verde's test) caused the dirty-brown stain indicative of dissolution.
9. On making careful movements of the joints of the extremities of the lower jaw, and of the occipito-frontalis, rigor mortis was found in several parts.

Thus of these nine tests, eight distinctly declared that death was absolute—the exception, the fluidity of the blood, being a phenomenon quite compatible with blood preternaturally fluid and at a low temperature, even though death had occurred.

10. There now remained the diaphanous test, which was carried out by the aid of a powerful reflector lamp yielding an excellent and penetrating light. The writer says: "To our surprise the scarlet line of light between the fingers was as distinct as it was in our own hands subjected to the same experiment. The mass of evidence was of course distinctively to the effect that death was complete; but, to make assurance doubly sure, we had the temperature of the room raised and the body carefully watched until signs of decomposition had set in. I made a visit myself on the succeeding day to assure myself of this fact."—*American Lancet.*

---

### Lumbricoid Worms in Young Children.

Miller (*Jahrbuch fur Kinderheilkunde*, Vol. xxxvi, part 3, 1893), reports a case of a child, three weeks old, who passed an ascaris under the following circumstances: The child was born July 10th. On July 17th the cord separated, on the 18th inflammation of the umbilicus began, which terminated in a grangrene of the navel, with perforation of the small intestine, which was bound to the belly wall at that point. The child constantly thereafter passed the stool through the artificial anus. On August 4th a living female round worm was passed from this opening; it measured six inches in length. This is the only case in which so young a child has been known to pass a lumbricus. The infection in this case, the author thinks, probably took place through impure water used in the milk, or in washing the nipple. He does not consider that the worm had any causative effect in the perforation of the intestine.

HER MOTHER.—I am surprised at Charles squandering so much money on a phonograph.
The Wife.—I am not. He always did like to hear himself talk.—*Brooklyn Life.*

## ARMY AND NAVY.

U. S. ARMY FROM MARCH 18, 1894, TO MARCH 31, 1894.

Captain William R. Hall, assistant surgeon, is relieved from duty as attending surgeon and examiner of recruits at San Francisco, California, to take effect upon the completion of his examination for promotion, and will then report in person to the commanding officer, Whipple Barracks, Arizona, Ty., for duty at that post.

So much of par 8, S. O., No. 60, March 12, 1894, from A. G. O. as relates to First Lieutenant Harlan E. McVay, assistant surgeon, is amended to direct him, on being relieved from duty at San Carlos, Arizona, by First Lieutenant Straub, assistant surgeon, to report in person to the commanding officer, Fort Huachuca, instead of Whipple Barracks, Arizona Territory.

Major Henry M. Cronkhite, surgeon U. S. Army, is relieved from duty at Fort Clark, Texas, and ordered to report in person to the commanding officer, Fort Reno, Oklahoma Ty., for duty at that post, relieving Capt. Wm. C. Gorgas, assistant surgeon. Capt. Gorgas, on being thus relieved, will report to the commanding officer, Fort Barrancas, Florida, for duty at that post, relieving First Lieutenant Robert S. Woodson, assistant surgeon.

First Lieutenant Robert S. Woodson, assistant surgeon, on being relieved by Capt. Gorgas, will report in person to the commanding officer, Fort McIntosh, Texas, for duty at that post and for field duty in the Department of Texas, relieving First Lieutenant Benjamin L. Ten Eyck, assistant surgeon. Lieutenant Ten Eyck, on being thus relieved, will report to the commanding officer, Fort Clark, Texas, for temporary duty at that post.

By direction of the President, Lieutenant-Colonel Samuel M. Horton, Deputy Surgeon General, will report in person to the president of the army retiring board, at San Francisco, California, for examination by the board.

---

THE physicians of the United States now number 118,453; New York leads with 11,171; Pennsylvania has 9,310, and Illinois ranks third with 8,002.

## NEWS AND MISCELLANY.

THE advance of surgery can furnish few more singular illustrations than is supplied by an operation in one of the London hospitals last week whereby the breast of a blackbird was fastened to a woman's face as a substitute for her nose, which had been so damaged that it had to be removed. The woman, who had been housemaid in a hotel, had been struck in the face by a descending lift, which caused the injury that led to the operation. The operation has proved perfectly successful, with every appearance of the woman being provided with a useful nasal appendage, though how it will perform its functions when the cure is complete remains to be seen.

---

A BOARD of medical officers will meet Monday, April 16, 1994, in Washington, D.C., for the purpose of examining candinates for appointment to the grade of Assistant Surgeon in the Marine Hospital Service.—*Ex.*

---

THE next meeting of the American Medical Association will be held at San Francisco, on the first Tuesday in June, 1894, instead of on the first Tuesday in May, in order to permit of a discussion of the Code by the various State Societies that meet just before the meeting of the National Association.—*Pub. Opinion.*

---

THE Arkansas State Board of Health has been given power to revoke the license of any physician who is guilty of habitual drunkenness.

---

THE Medical and Chirurgical Faculty of Maryland has placed in this dispensaries of Baltimore, cards ten by fourteen inches, reading as follows: "Watch a baby's eyes carefully for a week after birth. If they looked red or run matter, take it at once to a doctor. The child may become blind if not treated properly." The lesson taught by this card should be learned by every one in charge of an infant. No inflammation of an infant's eye is trivial. Home remedies are not to be trusted. Medical advice should be sought at once.—*Popular Health Journal*

## ORIGINAL ARTICLES.

### THE SURGICAL USE OF COCAINE.

B. MERRILL RICKETTS, PH.B., M. D., CINCINNATI, O.

I look upon cocaine as the greatest acquisition to the list of anæsthetics since the day of their discovery.

That it is in a measure dangerous cannot be denied, but as all powerful and useful drugs are more or less dangerous, we must console ourselves with the thought that a certain class of surgery and its good results could not be accomplished without them.

Admitting then that it is dangerous, even in the hands of those most skilled in its use, we are all the better prepared to rely implicitly upon its effects in producing anæsthesia for operations where it is desired not to produce unconsciousness.

What can be more dangerous than unconsciousness from any cause other than natural sleep?

Yet there are certain individuals whom it is better to make unconscious than to subject them to the fright which often attends operations, especially if the operation is to be grave or prolonged.

I have found that a few persons are not very susceptible to the effects of cocaine, while others are very much so. While this is the case, I do not believe that the effects are as have been reported, instantaneous. No more so than the effects of strychnia, atropia or morphia.

Such cases I consider nothing more than fright or ordinary faint. It is a physiological impossibility for a person to fall unconscious instantly upon the application of cocaine to the system in any way, especially if that person be in a normal physical and mental condition at the end of fifteen minutes from the time of its application.

There are more means of determining the safe application of cocaine than of chloroform or ether, and I believe that the bad results from the use of cocaine are to be more attributed to the operator than are the bad results of chloroform or ether. This I believe is due to the fact that physicians are not so familiar with the use of cocaine, and the exceeding uncertainty of chloroform and ether.

The amount that I have used in a given operation has varied from one-eighth to seven-and-one-half grains. The latter amount was used in a plastic operation for the restoration of both the left lower eyelid and right upper lip. This was in a case referred to me by Dr. D. D. Bramble and the amount was consumed within one and one-half hours.

The pulse reached 120 and respirations 24 per minute, but nothing more unpleasant arose.

On the other hand I have had the most alarming symptoms following the injection of but three-quarters of a grain (Merk's crystals) into the lower lip for the removal by cautery of an epithelioma.

This was in the case of a man age, 69, of a highly nervous temperament. The excitement was intense; the pulse 140 and respiration 30 per minute; he was generally discomboberated without unconsciousness or delirium.

He yelled at the top of his voice; pounded the couch, myself and assistant, Dr. Spargur. Talked rationally and expressed his chagrin that a man as old as he was should make a fool of himself, he also added that his condition was about the same as when he was drunk at the age of twenty.

Quietude was soon established and he was entirely over the stimulating effects at the end of one hour and a half.

In this case the symptoms were more aggravated than any of the six cases of poison that I have encountered among the one thousand in which I have used cocaine.

The other cases manifested similar symptoms, but very much less severe, but one, however, having delirium and none unconsciousness.

I have found that primary union is, with cocaine as with all local anæsthetics, less likely to take place. This may be accounted for, perhaps, by the hemorrhage poured out from the capillaries that have become dilated as the secondary effect of the cocaine. The first effect is to contract the capillaries which afterwards become over dilated, and thus allows hemorrhage to take place, which prevents union.

This has also been charged to the use of chloroform and ether.

I have used cocaine without a slough in the following operations, thus showing the very broad range of surgery in which it has been personally applied:

1. Circumcision.
2. Cutaneous tumors.
3. Subcutaneous tumors.
4. Varicocele (open operation.)
5. Hydrocele (removal of sac.)
6. Tubercular Glands.
7. Phymosis.
8. Periphymosis.
9. Internal Urethrotomy.
10. Removal of Ingrowing Nails.
11. Fistulæ (Sundry)
12. Hemorrhoidal Operations.
13. Amputation Finger and Toes.
14. Tenotomies.
15. Plastic Operations.
16. Incising Abscesses.
17. Neurectomies.
18. Neurotomies.
19. Preparing Surfaces for Grafts.
20. Removing Grafts.
21. Anæsthesia for Cautery and Caustic.
22. Amputation of Scrotum.
23. Removal of Testicle.
24. Ligation of Varicose Veins.
25. Exploratory Incision for Bone Disease.
26. Removal of Bones of the Feet and Hands.
27. Removal of Bone Spiculæ.
28. Removal of Foreign Bodies.

In conclusion I would offer the following *maxims.*

1. Solutions should not be made except at time of operation.
2. Cold water solutions will add materially to the good effects of the cocaine.
3. An operator should accustom himself to but one kind of cocaine and confine himself to the use of that kind as he does chloroform.
4. The operator should prepare the solution himself and not entrust it to an assistant.
5. Only small amounts should be used especially in the young, the old and in highly nervous persons.
6. Small quantities should be used in operations upon the face, head and neck.
7. Operations should be made as soon as possible after the area has become anæsthetised that as much as possible of the solution may escape through the wound and thus not enter the general circulation.
8. The finest needle should be used, and it's length should be sufficient to traverse the line of incision intra-cutaneously with but one puncture.
9. Intra-cutaneous and not subcutaneous injections should be made, because there is less of the drug absorbed and because there is no pain to result from cutting tissue beneath the integument.
10. The nearer the injection is to the end of the member the less is the amount of absorption.
11. The prepuce, fingers, toes, hands and feet can be constricted in such a way as to present to a considerable degree the entrance of the solution into the general circulation.

MRS. UPPERCRUST—"You go abroad a great deal lately, do you not Mrs. Newmonie?"

Mrs. Newmonie—"La! yes, my dear. Why, we're in Paris so much lately that I call us reg'lar Parisites!"—*Vogue.*

# THE EXTRACTION OF FRAGMENTS OF IRON FROM THE VITREOUS BODY WITH THE MAGNET.

F. C. HOTZ, M. D., CHICAGO, ILLINOIS.

The vitreous body of the human eye is an exceedingly sensitive tissue; it is very quickly affected by any disturbance of nutrition and it is very slow in the repairing of its deranged texture. After any injury therefore, it is apt to waste away, to shrink and seriously impair the functions of the eye. On account of this great sensitiveness of the vitreous the removal of foreign bodies with forceps or scoops, which instruments necessarily caused considerable derangement of its texture, was usually followed by so disastrous results that it was seldom attempted, and that the presence of a foreign body in the vitreous was generally regarded as equivalent to the loss of the eye.

It was, therefore, a most happy idea of Dr. McKeown, of Belfast, in 1874, to employ for the extraction of an iron chip, a magnetic probe which through a scleral incision was slowly passed into the vitreous down to the foreign body, and the iron attracted by the magnetism was found attached to the probe when this was withdrawn from the eye. As the probe passed in and out over the same route it caused but very slight derangement of the vitreous and the eye recovered so well that the patient was able again to read small print.

Dr. McKeown's instrument was a simple bar magnet, 8 inches long and 1-8 inch thick tapering off to a point at both ends. And though since then the ingenuity of men has furnished us with instruments much superior to his, both in power and shape, his merits remain undisputed of having opened a new field for ophthalmic surgery.

There are now two kinds of instruments in use, the *permanent magnet* and the *electro-magnet*.

As an excellent representative of the first kind I show you here the permanent magnet constructed by Dr. Gruening, of New York, in 1880, and will describe its construction by the inventor's own words.* "I joined several magnets into a bundle, thus making a powerful magnetic magazine. * * * The two extremities of a number of magnetized steel rods placed parallel to, and at a little distance from each other, are fitted into iron caps one of which is provided with a delicate point of malleable iron, 32 mm. long, 1 mm. wide and 0.3 mm. thick. This point is powerfully magnetic, sustaining with ease, a weight of 15 grammes. Chips of iron weighing from 1 to 50 centigrammes, when placed into the vitreous of recently enucleated animals eyes, are attracted toward the point at a distance of 1 to 5 mm., and withdrawn with the greatest facility." When not in use the point is screwed off and the magnet placed in an iron frame to preserve its magnetic power.

When we consider that the weight of the particles of iron found in the vitreous body seldom exceed one centigramme, we must admit that Gruening's magnet is certainly powerful enough for the purpose. It has also the advantage of great convenience; for it is light, easy to manipulate, portable, and ready for use at any time and in any place. The only faulty point which has been urged against this instrument, is that it gradually loses power. But while admitting this fact, I can easily convince you by a *demonstratio ad oculos* this loss of power is so infinitely small that it can scarcely be appreciated even after many years. This magnet was bought in 1881, and as you see still lifts this key weighing nearly half an ounce. And then should the instrument become actually too weak, the steel rods can be remagnetized by an electric company at a very small expense.

In the electro-magnet—as the name indicates—the magnetism is developed by an electric current circling round a piece of malleable iron. Its use, therefore, requires a battery and connecting wires, and its efficacy is entirely dependent on the perfect working of the electric apparatus. All this makes the electro-magnet a more complicated and cumbersome instrument than Gruening's magnet; nor is it as convenient as the latter, because whenever you wish to use it you have to have a battery with you. The only thing in its favor is its greater power; but I dare say a fragment of iron which a good Gruening mag-

*New York Medical Record May 1, 1880.

net cannot extract from the vitreous, will not be brought out by the more powerful electro-magnet.

I am free to make this assertion upon the ground that the electro-magnet has proved a failure in the hands of our surgeons under precisely the same conditions under which I was unable to extract the small particle of iron with a Gruening magnet in the following case :

*Fragment of iron, weighing 2 milligrammes, in the vitreous one week; vitreous cloudy, but iron visible; magnet failed; eye enucleated.*

The bit of iron had entered the eye by the sclero-corneal border and without wounding the lens had made its way into the vitreous. At the time of the examination, one week after the accident, the eye was considerably inflamed but still could count fingers; the pupil readily dilated under atropine and the lens was quite clear; the vitreous was hazy, the obscuration being decidedly more pronounced on the temporal than on the nasal side; and in the denser temporal cloud a bright shining body could be seen with the ophthalmoscope. An incision was made through the tunics of the eyeball below the external rectus muscle, and the point of Gruening's magnet was introduced in the direction where I had located the iron scale. But repeated efforts with the magnet were unsucessful and finally I had to enucleate the eye. Immediately after enucleation I removed the cornea, iris and lens, being careful not to disturb the vitreous, and I could trace the track the magnet had left in the vitreous, from the scleral incision straight on to the foreign body, a minute scale of iron. It was, therefore, evident the point of the magnet had undoubtedly been in contact with the iron fragment, but why then did it not bring it out? This question was answered by the following experiment : I again introduced the magnet through the scleral incision and slowly passed it along the visible track in the vitreous toward the foreign body, and when it was yet one millimetre from the iron this jumped and clung to the point of the magnet; and when the latter was slowly withdrawn the iron followed it for a distance of 2 or 3 millimetres; but then it suddenly sprung back to its former place as if forcibly jerked back by an elastic string. This experiment was repeated several times and always with the same result. The whole vitreous was opalescent, but around the metallic scale it was streaked with white fibrinous strings which held the foreign body so firmly within their grasp that when I tried to remove it with the point of a scalpel, the whole vitreous was lifted up, and it required considerable traction to break these resisting bands. It is obvious that against such resistance any magnet would have been powerless.

Under much more favorable conditions and with very good results was the magnet employed in the following two cases:

Case I. *Chip of steel, weighing 9 milligrammes, in the vitreous 24 hours; magnet successful; good vision restored.*

The steel entered through the sclera 6 millimetres from the nasal margin of the cornea and could be plainly seen with the ophthalmoscope in the center of the vitreous. The small wound in the sclera was enlarged, the point of Gruening's magnet introduced in the proper direction, and on the second attempt the chip of steel was brought out. The conjunctiva was closed over the scleral wound by a fine silk suture, and both eyes were bandaged for 5 days. The recovery was very rapid and one month later the sight was almost normal.

Case II. *A scale of iron, weighing 3 milligrammes, in the vitreous ten days; magnet successful, eye recovering with traumatic cataract.*

This case is remarkable for the unusual tolerance shown by the eye to the pressure of the foreign body in the vitreous, inasmuch as after ten days there were no signs of inflammation. The small scale of iron had entered through the cornea and made its way through the temporal portion of iris and lens into the vitreous where it could be seen as a bright shining body though the lens was already partly opaque. It was successfully extracted with the electro-magnet through a scleral incision, and the eye made a quick recovery, but the lens, of course, became entirely opaque.

It is evident the operation promises the best results if it is undertaken at a very early period, before the iron has been enveloped in a dense exudate, and before the lens or the vitreous or both have become so cloudy as to render an ophthalmoscopic examination impossible.

You have seen that the movableness of the iron fragment is an indispensable condition for the success of the magnet operation; and another condition almost as essential is this, that the foreign body can be seen, or at least located, with reasonable accuracy. For if we do not know its location in the vitreous we are truly and literally fishing in the dark and trusting to good luck to find it. But "luck" is an element we should not reckon with in surgical operations. In 33 cases where the fragments could not be seen in the vitreous and the surgeons "went it blind and for luck," the iron was extracted in 14 only, while the operation was successful in 13 out of 15 cases in which the foreign body could be seen; and the two pieces which could not be extracted, were found to be embedded in the retina.

But before we decide upon the magnet operation we have not only to consider the question whether the chances are favorable for the extraction, but we should also consider the far more important question whether we have good and sufficient reason to believe that the removal of the foreign body will save the eye. I, for my part, at least, have always taken this position, that the operation is not performed for the purpose of proving the possibility of removing particles of iron or steel from the vitreous, but that its ultimate aim is the preservation of the eye either as an organ of vision, or, at least, for its cosmetic value; for every one would rather keep his own eye though it be blind, than to wear an artificial eye. Always acting on this principle that the operation was to benefit the patient, I could never persuade myself to undertake it on an eye in which the lesion was so serious, or the inflammation induced by the foreign body so violent and extensive, that I was convinced disfiguration and atrophy of the eyeball would be the inevitable result even should I succeed in extracting the particle of iron. What satisfaction can it be to the patient to know the iron was successfully extracted with the magnet if his eye does not recover, or has to be enucleated soon afterwards for fear it would cause sympathetic inflammation of the other eye? Is it not more rational, is it not far better for the patient as well as the surgeon under these circumstances to abstain from the magnet extraction and to remove the eyeball at once.

We have already learned the magnet operation is not always successful; we have seen it fail to extract the iron or steel in 21 out of 48 cases which I found reported in the journals. But if now we examine the reports of the 27 successful extractions in order to find out how many patients receive a lasting benefit and what the condition of those eyes was, which were actually saved by the operation, we receive the following information. In 6 cases the operation was done very soon after the accident before inflammation had set in, and all 6 eyes recovered. Of 13 eyes which showed a moderate degree of inflammation and more or less haziness of the vitreous, 10 were saved; but of 8 eyes with violent inflammation and cloudiness of the vitreous none could be saved, they all had to be enucleated because the irido-choroiditis continued although the foreign body had been removed. These results sustain my opinion of the impropriety of operating on an eye in the advanced stage of inflammation. But I am well aware these views are not shared by all surgeons. For among those 48 cases in which the magnet had been tried, I found a goodly number of eyes which manifestly were in a hopeless condition before the operation; eyes with their tunics extensively lacerated; eyes with the vitreous chamber filled with blood; and eyes showing the signs of atrophy, that inevitable consequence of severe traumatic irido-choroiditis. To operate on such eyes is, in my opinion inexcusable, for neither science nor the patient can gain by it. But for some surgeons the presence of a piece of steel or iron in the vitreous seems to be a sufficient indication for the use of the magnet, no matter what condition the eye is in—because in their anxiety to increase the list of their operations they sometimes forget that the welfare of the patient should always take the first rank in all our deliberations and actions.

ASSYRIAN RECORDS.—Layard, in his "History of Nineveh," mentions that the national records of the Assyrian Empire were written on bricks in characters so minute as to be scarcely legible without the aid of a microscope, and that, in fact, a variety of this instrument was found among the excavations.—*Boston Commonwealth.*

# COMMUNICATIONS.

## THE IMPORTANCE OF EARLY RECOGNITION AND TREATMENT OF OBSTRUCTIVE DISEASES OF THE UPPER RESPIRATORY TRACT.*

JOSEPH S. GIBB, M. D.,† PHILADELPHIA.

The introduction of a subject so time-worn and stale might require an apology were it not that notwithstanding there is a plethora of literature there still remains a singular indifference and lack of appreciation of the merits of the matter in the minds of the general practitioner. Doubtless much of this is due to the very voluminous character of the literature, which tends rather to interest those for whom the subject has an especial attraction. We read much of the histological structure of the various hypertrophies, and numerous are the instruments introduced for their destruction. We read less of the best means of demonstrating their existence, the etiological factors concerned in their production, and the prophylactic measures which may be adopted to prevent their development.

Perhaps no single abnormal condition is productive of more marked alterations in physical beauty and healthy functions than diseases producing obstruction in the upper respiratory tract. The anxious and watchful mother views with sorrow the freckling or tanning of her child's face. How much more disagreeable than these are alterations in the facial lines to such a degree as to cause a face to be expressionless; and when to this is added partial deafness, with all its unpleasant effects, we have a picture which any careful mother should strive to avoid. Were as much care bestowed on the important functions of the nasal chambers as is generally given to the skin or other tissues more directly under the eye, we would have fewer of these unpleasant pictures. Nor is this marring of physical beauty the sole deleterious result of these conditions, it can be proven that serious and perhaps grave interference with important functions follow in its wake.

In order to have a proper appreciation of the importance of the subject we will review for a moment, and in a cursory manner, the anatomical structure and physiological purposes of the nasal chambers and their contiguous structures.

The bony nasal chambers consist of three scroll-like bodies, the turbinate bones, two of which, the middle and inferior, are accessible in the living subject, which form the sides of the chamber. A septum, separating the nasal chambers, which is reinforced by a plate of cartilage in the recent state. These turbinated bones divide the nasal chambers into three meatuses—superior, middle, and inferior—into which open the various sinuses or foramina which communicate with the accessory cavities—namely, the frontal sinus, the ethmoid and sphenoid cells, the antrum of Highmore, and also the lacrymal duct. All these structures in the living subject are covered with mucous membrane well endowed with bloodvessels and nerves, whilst over the turbinate bones the tissue is erectile or cavernous.

The situation of these chambers, the peculiar construction of the bones, the unusually large surface of mucous membrane for so small a cavity, and the very generous blood supply, bespeak important functions. Bosworth claims three: (1) the first and very important function in respiration; (2) an aid in phonation by acting as a resonant chamber; (3) as an olfactory organ.

The atmospheric air as it passes through the nasal chambers is brought in contact with a comparatively large surface of mucous membrane which is rendered warm by the free blood-supply and moist from the secretion of the numerous mucous glands therein contained. The effect of this contact is first to abstract from the air

*Read before Philadelphia County Medical Society, March 14, 1894.

†Instructor in Laryngology in the Philadelphia Polyclinic; Surgeon-in-charge of the Ear, Nose, and Throat Department of the Episcopal Hospital, Philadelphia.

dust and other foreign bodies, and secondly to add to the inspired air warmth and moisture. This latter function is most important. It has been computed that over 7000 grains of water are expired from the lungs in twenty-four hours; and Aschenbrandt has demonstrated by a series of carefully conducted experiments that the source of this moisture is in the nasal chambers.

From this brief and very imperfect glance at the anatomical position and functional purposes of the nasal chambers we may draw a few important lessons. Interference with the proper and easy inspiration of air through the nasal chambers is productive of diseased conditions, not alone of those organs themselves but of the more important respiratory structures within the chest.

It cannot be doubted that inspiration of air into the air vesicles imperfectly warmed, deprived of the moisture which Nature intended it should have, must exercise a deleterious influence on the delicate mucous membrane lining these cells. I am not ready with statistics to prove the relationship between pulmonary and bronchial affection and obstructive diseases of the upper air tract, nor do I deem it necessary, for it is a matter of common experience and observation that those children whose nasal chambers are obstructed either directly by hypertrophies, polyps, etc., or indirectly by hypertrophied pharyngeal or faucial tonsils, are sunken-chested, prone to attacks of acute bronchitis and coryza, and in many respects are less healthy than other children. I am well aware that these conditions are often the result of a constitutional vice which in itself renders the subject less robust, still I am more than ever convinced that removal of the local effects of this diathetic condition results more effectually in a return to a normal condition than any plan of treatment directed solely to the condition itself. Nor is it alone the respiratory tract that suffers from these abnormal states. I have before remarked that children so afflicted are apt to be in a condition of poor health generally, and it has occurred to me that perhaps this may be not entirely due to the diathetic condition which is so frequent a concomitant, but rather that the lungs, being supplied constantly with a vitiated air, *i. e.*, air insufficiently warmed and moistened, failed to supply the blood with a healthy, proper pabulum and hence the tissues suffer. Be the explanation what it may, we must not lose sight of the fact that a condition of ill health frequently does exist and we should bend our energies to ascertain the cause and seek its remedy.

It is not the object of this paper to elaborate on the various methods of treatment, but rather to inquire into the causation and to endeavor to point out means which may be taken to ameliorate the conditions existing and to prevent the development of more serious ones. Especially is it desired to inquire into the causative influences of obstructive diseases of the upper air-passages in young children.

Eliminating all those effects of imperfect or perverse fœtal development such as occlusion of anterior or posterior nares, cleft palate, etc., we have conspicuously prominent in the catagory of obstructive lesions in the upper respiratory tract hypertrophic conditions of the turbinate bodies, of the pharyngeal, faucial, and to a lesser degree the lingual tonsil.

A glance at the records of any of our large throat and nose clinics will convince one that these abnormal conditions are far from rare; nor does even this showing give us a thoroughly accurate conception of their frequency. Too common is it to ignore or carelessly treat the various catarrhal symptoms presented to us, and this indifference on the part of the profession has led to a corresponding indifference on the part of the laity, so that only those cases of pronounced obstruction are brought to the notice of the general practitioner. Were the nasal speculum used as freely as the stethoscope or clinical thermometer we would be astonished at the result. Again, certain hypertrophic conditions have but comparatively recently received any measure of attention from the profession. Though faucial hypertrophies have been observed and studied from remote times, it was not until a very recent date that Meyer gave to the profession a clear idea of the significance of hypertrophic conditions of that collection of adenoid tissue at the vault of the pharynx known as the pharyngeal tonsil; nor is the importance of the subject to-day appreciated by the rank and file of the profession, notwithstanding that much has been written about it and many instruments devised for its removal. Situated

as it is in a somewhat inaccessible or rather unobservable portion of the upper pharynx, it is only by the use of the rhinoscope that its presence can be clearly demonstrated; this being the case it is patent that it must be frequently overlooked.

With these facts before us it is clear that, whereas our clinics show us that these states are common, they give us no adequate conception of their prevalence.

At the clinic of the Episcopal Hospital it is the custom to carefully examine the nasal cavity, the pharynx, and post-nasal surfaces in every case that applies for treatment, irrespective of the fact that the subjective symptoms point to lesions in this or that locality; and in children of tender age, where a rhinoscopic examination is not feasible, if there is any suggestion of disease in this locality a finger is introduced back of the soft palate and over the vault of the pharnyx to demonstrate by tactile sense the presence or absence of any abnormality. It is surprising as a result of this procedure to note the number of cases in which there are lesions of the upper pharnyx of which the symptoms have been overlooked by the parents.

In considering the etiology of these hypertrophies it is as well to treat of them collectively, for whereas they are often separate and distinct lesions and exist independently, they are often associated and their etiology, so far as our knowledge goes, is in many respects similar.

In the case of the glandular tissue there can be no doubt that in a few instances these hypertrophies are congenital, doubtless the effects of an inherited vice—syphilis or scrofula—carrying out the well-known tendency of these dyscrasiæ to affect lymphatic and glandular tissue. Though this view is combated by no less authority than Meyer, who leans to the view that it is always an inflammatory process in a tissue which normally is largely developed in infancy and childhood, at the same time it is difficult to explain the presence of this state in very young infants unless we presume this inflammatory process to have taken place during its prenatal existence. Those cases developing subsequent to birth donbtless have as a starting-point an inflammatory or catarrhal origin.

We have demonstrated the frequency of hypertrophies of the glandular tissues and turbinates in children, and have admitted a few cases may be congenital, which leaves the vast majority to have its development subsequent to birth; and as it is our belief that its causation lies in some condition outside of the child, at least, in part, it is now our endeavor to seek out those causes and, if possible, lay down certain laws looking to their eradication or, at least, amelioration. Here as with many other diseases of insidious approach, an early recognition is productive of much good.

Among the general causative agencies which it is not entirely within our power to relieve, may be mentioned atmospheric conditions incident to residence in temperate climes, and especially near the seaboard; the method of heating houses in cities by dry air frequently derived from an unsanitary source; carelessness in the dressing of infants and trusting them too much to the care of servants who unnecessarily expose them. All these and others exercise an influence in the production of the disease, but only in a general way. The prophylactic remedies are obvious and suggest themselves.

The various catarrhal conditions which the above enumerated disturbing influences of our environment occasion, are of much importance from an etiological standpoint. There can be no doubt that it is here we have the starting-point of the hypertrophic process. A simple coryza is neglected; the child is not even protected from the causes which produced it—the result, one coryza succeeding another the entire season. The effect of a long-continued inflammatory process is precisely the same in the nasal and pharyngeal tissues as in the other tissues of the body—namely, increase in the connective-tissue growth, increase in the cellular growth. And it is just here by a knowledge of the effects that the family physician's advice and counsel can be of so much value and save so much misery and suffering to the child—so much mental anxiety and mortification to the parents. I believe that parents should be taught that a coryza is by no means so simple or harmless an affair as is commonly believed. It is better to err on the right side—better by far to give some attention (possibly needless) to a few attacks of coryza than to sit quietly by doing nothing and permitting the production of obstructive masses in the upper air-passages that

may alter the child's expression and possibly injure the health.

Parents should further be taught that repeated coryzas indicate a diseased condition of the nasal or pharyngeal mucous membrane demanding prompt and thorough treatment. The physician should himself insist on a careful examination aided by the speculum and rhinoscopic mirror, and should lay down a plan of treatment which his ingenuity will suggest, and persevere with it until the conditions yield; and I believe in this way, and in this way alone can we hope to have any measure of success.

Conspicuous in the category of special causative agencies may be mentioned the eruptive diseases of childhood, and especially those in which the fauces and nasal chambers are involved in the diseased process. Foremost among these may be mentioned diphtheria. The well-known tendency of diphtheritic processes to attack glandular tissue is well exemplified in the post-nasal spaces. We are familiar with the appearance of the diphtheritic membrane on the tonsils, but usually the examination of the other mucous surfaces is not made, and we remain in ignorance as to the extent of this process into the nasal chambers and vault of pharynx. Doubtless if careful examination was carried out in every case we would find the proportion in which these structures are involved to be very large. I have no doubt that many of the cases of so-called re-infection are in reality those in which there has been an involvement of the pharyngeal tonsil in the diphtheritic process. When an examination of the tonsils reveals an absence of the familiar membrane and a subsidence of the inflammatory condition, we are lulled into a sense of security and perhaps relax in our vigilance unmindful of the fact that the disease is perhaps making insidious inroads at a spot beyond our unaided view. However, we are not concerned with this at present; sufficient is it for us to know the extreme susceptibility of the mucous surfaces in this disease.

After the subsidence of the diphtheritic process it is very common to have a catarrhal condition continuing for a considerable period; this is especially noticeable in cases in which the nasal mucous membrane has been implicated; though it frequently occurs where there has been no perceptible involvement of the nasal chambers, and I believe it is just in these cases that there has been a diseased process going on at the vault of the pharynx. The explanation of this mucous discharge and other evidences of a catarrhal condition is doubtless due to alterations in the nutrition of the part, in consequence of the high grade of inflammatory action, and also to septic absorption. Were an examination made at this time we would likely find a hypertrophic condition either in the nasal turbinates or the pharyngeal and faucial tonsil. Though doubtless the majority of these cases do well without any special treatment directed to the part, yet in a certain number the catarrhal condition persists, and especially is this likely to occur in those children who seem prone to catarrhal states, and the foundation is laid for the formation of masses of hypertrophied tissue.

The beneficent offices of the family physician can be here admirably employed. It is not wise to pass over lightly the persistence of a catarrhal state after the subsidence of the inflammatory symptoms. Treatment employed at this time and persisted in until an amelioration takes place, can be productive only of good.

Scarlatina, as is well-known, expends at least a part of its energy on the mucous membrane of the fauces; though, unlike diphtheria, rarely involves the nasal chambers. Here the inflammatory action is so high, often to the production of false membrane, as to exercise a baneful influence upon the nutrition of the tissue and aid in the production of hypertrophies. We are all familiar with the fact that hypertrophies of the faucial tonsils are a frequent sequela of this disease. The same process that gives rise to hypertrophies in this tissue is at the same time exerting its influence on the tissues of the vault.

It is needless to dwell on this; the too familiar sight of catarrhal conditions as sequelæ of scarlatina precludes any argument to the contrary as to its position as a causative agent in the conditions under consideration. Nor is it hardly necessary to refer to the necessity for prompt treatment—one word, however on this point. It seems to me an imperative duty on the part of the medical attendant to insist on an examination, and if necessary subsequent treatment in every case where a ca-

tarrhal condition evidenced by a mucous or mucopurulent discharge from the nose, a thick voice, and mouth-breathing persists, after all evidences of the exanthemata have passed away.

Measles, though commonly regarded as a light and insignificant disease, is exceeding apt to leave some trace of its existence. The explanation of this is evident. Not commonly menacing life, it is, however, very active in its attack, and this activity is exerted on the mucous surfaces in the entire respiratory tract. Mothers should be informed of the fact that with care the course of the disease will be benign, but without it there is extreme probability of a catarrhal affection with all its unpleasant consequences being left as a sequelæ. And here, as with others, active treatment should be insisted upon if the catarrhal symptoms persist after the subsidence of other evidences of the exanthemata.

The other exanthemata and febrile diseases, such as rötheln, variola, varicella, typhoid fever, etc., exert a certain amount of influence as causative agents, but only in a general way, as any alteration in health will do. The diseases mentioned, viz., diphtheria, scarlatina, and measels, exert a special influence because the diseased condition seems to expend itself on the mucous surfaces, producing alterations and perversion of function.

The clinical picture presented by sufferers from obstructive diseases of the upper respiratory tract is absolutely characteristic, and especially is this true as regards the alteration of facial lines and changes in expression. Naturally this obstruction to the entrance of air by the normal route, viz., through the nose, necessitates its seeking some other mode of ingress to reach the lungs; the only other way is through the mouth, and hence we have the condition of mouth-breathing with all the discomfort and unpleasant effects which such a condition entails. Long-continued mouth-breathing brings into play muscles about this orifice not usually called upon for excessive work, and at the same time nominally puts at rest muscles about the nose whose functions are not called into play; the result is an alteration of facial expression to such a degree in well-marked cases as to give to the child a stupid, almost idiotic appearance. The obstruction in the case of the pharyngeal tonsil may become so excessive as to encroach on the pharyngeal orifice of the Eustachian tube, interfering with the proper supply of air to the tympanic cavity, thus inducing catarrhal or inflammatory conditions of the mucous lining of this tube and also of the tympanic chamber. The result of this is dullness of hearing or even complete deafness.

The normal course of the secretion from the numerous mucous glands in the nasal chambers is obstructed and hence flows back into the naso-pharynx; added to this we have a greatly increased secretion from the adenoid vegetations at the vault. During sleep this mucous collects in the pharynx, and as the child is obliged to breathe through the mouth, we have associated loud snoring with rattling and gurgling of air through the mucous secretion; hence the sleep of the child is restless and fitful and the annoyance to other members of the household excessive.

We have then as the salient features of a case we are attempting to portray: mouth-breathing, snoring, rattling of mucous in the fauces, and disturbed sleep; a dull, listless expression of countenance; hardness of hearing, and in many cases impairment of general health, causing the child to be anæmic, sunken-chested, prone to catarrhal attacks, and of stunted growth.

Much has been written and various are the opinions as to the treatment of these distressing conditions. We are not concerned in this article whether it is the proper method to remove adenoid growths by forceps, curette, or finger; to diminish hypertrophied turbinates by means of galvano-cautery snare or escharotics, but a few words in conclusion as to the management of cases in their incipiency may not be amiss

Mothers should be urged not to neglect a persistent snuffle in her child, to regard as trivial the continuance of a mucous discharge after diphtheria or the exanthemata. Physicians, on the other hand, should not pass these complaints lightly by ignoring them or directing in an indifferent manner some simple and likely inefficient remedy.

The management of hypertrophies at this early stage is as simple as the results are happy. After a careful examination the nares and upper pharynx should be cleansed of mucous by an antiseptic and detergent spray, *e. g.*, Dobell's solution,

Seiler's tablet, Listerine in diluted solution, etc., and then applications made to the affected mucous membrane of an astringent or alterant, depending on the condition of the parts. Should we find simply an increased secretion with no appreciable alteration in the turbinates, tonsils, and surrounding tissues, it is likely we will accomplish all that could be desired by directing spraying of the nares thoroughly by one or other of the solutions mentioned faithfully until the membrane presents a normal appearance and the secretion ceases.

In cases still farther advanced in which we find the turbinates quite red and somewhat swollen; the pharyngeal tonsil secreting more mucus than normal, and rather large; the faucial tonsil red and somewhat hypertrophied, we will find it advantageous to use some application to diminish the inflammatory condition. These applications maybe made quite painless by spraying the parts with a 5 per cent. solution of cocaine or introducing a cotton tampon saturated in the same solution. In the nares a solution which has gained favor in the various clinics devoted to these diseases is that of iodine. The strength of the solution may be graded by the severity or obstinacy of the case. It is well to begin with a weak solution, increasing the strength as the necessities of the case demand. In some cases which resist this plan of treatment a touch of the fused bead of chromic acid along the turbinates will often accomplish the desired object; this latter plan should be immediately followed by the antiseptic spray to dilute and limit the destructive power of the escharotic. It is merely necessary in these early cases to touch the mucous membrane lightly to produce a superficial eschar; the resulting slough and subsequent contraction will so squeeze the blood-vessels as to bring about the desired diminution in the size of the tissues.

The pharyngeal tonsil also in many cases respond satisfactorily to application of iodine on a pledget of cotton carried by an applicator so curved as to pass readily behind the soft palate and up to the vault. Glycerole of tannin has been found to act very happily, though perhaps a little more unpleasant in its effects. The application of chromic acid (fused) to a pharyngeal tonsil should not be advised, though undoubtedly as useful as in the nose, unless the operator is steady and familiar with making applications by the aid of the rhinoscopic mirror.

It would be hardly necessary to refer to the treatment of catarrhal and slight hypertrophic conditions of the faucial tonsils the result of the causes named, were it not that here, in spite of the ready accessibility of the part, they are subject to neglect. The same process of cleansing is as necessary as in the other hypertrophies, after which an application of a solution of 60 gr. to the drachm of nitrate of silver, glycerole of tannin, or in stubborn cases producing a superficial slough by fused chromic acid, will probably answer every purpose.

In the more advanced cases or in those which fail to respond to the above-outlined plan of treatment and a steady increase of the hypertrophied tissues occurs, there is but one plan which should be carried out at as early a date as possible, namely, a destruction of the hypertrophied tissue. The various plans to accomplish this object will not be touched upon, but can be readily learned by consulting any of the modern treatises devoted to the treatment of diseases of the nose and throat.

In recapitulation the object of this paper has been to call attention to the following points:

1. The importance and desirability of early attention to diseases of the upper respiratory tract consisting of the nose and nasopharynx.

2. The production of alteration in nutrition and possibly pulmonary and bronchial troubles by hypertrophic conditions of the upper respiratory tract.

3. The etiology of these states referring to the influence of environment and especial mention of diphtheria and the exanthemata as prominent factors in this category.

4. The prevalence of these conditions.

5. Carelessness and indifference in both physician and patient as to the various catarrhal states which are believed to be the precursors of the diseases under consideration.

6. The necessity of early treatment and the power for good exercised by the family physician in these troublesome conditions.

7. The clinical picture presented by these unfortunates, laying especial stress on the alteration in facial expression and the distressing and annoying condition of the child during sleep.

# A CASE OF SPONTANEOUS ABSORPTION OF A CATARACTOUS LENS.*

T. B. SCHNEIDEMAN, M. D.†

A. B., aged 65 years, male; vision of the left eye began to grow dim twenty years ago. The dimness increased until he became entirely blind in that eye, two years after the trouble began. Has never had pain, injury, nor inflammation in the eye. At Wills Eye Hospital, which institution he visited at that time, one of the surgeons informed him that he had a cataract and advised operation for its removal, but the patient did not consent on account of the excellent vision which he enjoyed with the other eye.

The blind eye remained in the same condition, so far as the patient knows, until 5 years ago, when he observed a slight improvement. The sight continued to improve slowly, so that he was again able to distinguish large objects, the entire course being unattended with any pain.

*Present condition.* Eye of normal appearance externally; pupil round and reacts to light and convergence. Iris markedly tremulous with the movements of the eyeball. Fundus reflex of normal intensity throughout region of the pupil, except at the upper part where it is concealed by a dense gray membranous opacity. Closer examination shows that this membrane is freely movable, the lower extremity floating behind the iris, the upper portion being attached above. The membrane is evidently the remains of the capsule of the lens. There were a few small opacities in the vitreous, the rapidity of their movements proving that structure to have become fluid. The fundus was distinctly visible in all its details, and could be seen with a convex lens (+ 11). The nerve is decidedly pale and presents a shallow cup; the vessels are narrow and fewer than in health. The nerve is evidently atrophic. With + 11 the vision equals 12|200. The organ in its present condition presents exactly the appearance of an eye operated upon successfully by discission.

The best attainable vision with the correcting lens is low, but this is due to disease (atrophy) of the optic nerve and not to opacity of the media. Low as is the vision, if the case had been operated upon the result would still have been counted a success.

The interest in this case attaches chiefly to two points: 1. Complete absorption of the lens, together with its nucleus, occurring in a subject of the age of this patient; and 2. That this process should have gone on to completion without the supervention of glaucoma. Dislocation of an opaque lens is met with not infrequently, but the organ is found unaltered, at least as to the nucleus, years after the luxation has occurred, its presence in the anterior chamber causing repeated and destructive attacks of inflammation from the increase of tension to which it gives rise.

Absorption is, of course, the rule in the youthful eye when the fluid of the anterior chamber is permitted to gain access to the substance of the lens proper—a fact which is taken advantage of in the operation of discission. The infrequency of this occurrence in the adult eye is shown by the unsuccessful attempts of Beer to apply the same procedure to such eyes before the indications for the operation had been established; of twenty-nine eyes subjected to the operation, success was attained in only a single case.

The possibility of rupture of the zonula is greater where the lens has become opaque, because this structure participates in the degenerative changes which the whole lens system undergoes; and the more advanced these changes the greater likelihood of such an occurrence, as in hypermature cataract with considerable shrinking and atrophy of the organ. Such shrinking of itself exerts traction upon the suspensory ligament, and such traction may well be partial and affect one portion of the circumference more than the rest, and which yields at that point; in the case reported this point was situated at the inferior attachment.

The fluid condition of the vitreous noted was probably an important factor in bringing about the result; this condition may very likely have existed prior to the lesion of the suspensory liagment, the lens having lost some of the support pos-

*Read before Philadelphia County Medical Society, March 14, 1894.

†Adjunct Professor of Diseases of the Eye, Philadelphia Polyclinic; Assistant surgeon to Wills Eye Hospital; Oculist to St. Christopher's Hospital Dispensary.

teriorly and normally furnished by the contents of the vitreous chamber in consequence of the alteration in that structure.

The text-books refer to dislocation of the lens as a late event in the history of cataract. Thus Fuchs observes: "The shrinking of the hypermature cataract affects not only its thickness, but also its equatorial diameter. In proportion as the latter diminishes in size, the zonula of Zinn is stretched, and thereupon undergoes a corresponding atrophy of its fibres. Consequently, the attachment of the lens becomes imperfect. Spontaneous luxation even of the lens may take place through partial or total rupture of the zonula. . . ." Again, after remarking "that spontaneous restoration of sight is extremely rare in senile cataract with a a hard nucleus," he admits the possibility of such occurrence in three ways: By the resorption in the exceptional cases not only of the cortex, but also of the nucleus to such an extent that nothing but slight opacities remain. The other possibilities to which he refers are the formation of a Morgagnian cataract and spontaneous dislocation of the lens, but without absorption.

Soelberg Wells speaks of dislocation due to gradual relaxation or elongation of suspensory ligament, or its partial rupture. In such a condition, he adds, a very slight shock to the eye, which may have been unnoticed by the patient, will produce dislocation of the lens.

Berry (*Diseases of the Eye*, p. 100) speaks as follows: "After the condition of maturity has existed for a longer or for a shorter time, further changes may take place, which are characterized as stages of hypermaturity. The opaque cortical substance may to some extent shrivel from loss of fluid, and in this way a little of the sight—as a rule, only a very little—be regained."

The gradual improvement in the vision raises the question whether the lens was actually dislocated or whether the rupture extended into the anterior capsule, giving access to the aqueous humor, causing gradual absorption of that organ as in the operative procedure of discission, or whether the improvement can be explained by the solution of the opaque lens after dislocation into the anterior chamber. The latter is the position usually occupied by the lens after luxation.

Perhaps the gradual improvement observed by the patient depended upon a partial displacement of the opacity. This cannot be determined with certainty; the patient did not come under observation until the process, whatever its exact nature may have been, had gone on to completion. In any event complete absorption of the lens in the adult is a rare termination of cataract.

## A REPORT OF EIGHT CRANIOTOMIES; WITH REMARKS ON THE TREATMENT OF LABOR IN CONTRACTED PELVES.*

DANIEL LONGAKER, M. D.

When labor is rendered pathological by the existence of contraction of the pelvis, certain deviations from the normal occur which it may be well for us to glance at here. These have reference to the fœtus and to the process of dilatation. Normally the head rests in the pelvis before a single pain occurs, even in a multiparous patient and in a primiparous weeks before the advent of labor partial descent and partial flexion will have taken place. In the latter the absence of this adaptation on the approach of labor is significant of disproportion between the presenting part of the child and the pelvis, and either the head is not in relation with the pelvic inlet or it is too large.

So long as engagement has not taken place even the experienced may be in doubt of the nature of the presenting part on mere digital examination. Too much emphasis cannot be placed upon this one point. A pelvis relatively empty and the presenting part reached with difficulty by the examining finger means, very frequently, the existence of narrowing. This is true even if found very early in labor and in a primipara before labor. All such cases demand the fullest investigation. If the attendant is not competent to make a careful estimate of the degree of pelvic narrowing, and finds this suspicious sign of its existence, he should request expert aid without delay. It will not do to leave such a case to chance. It is inexcusable to conclude, that since the pains are in-

* Read before the Philadelphia County Medical Society, March, 17, 1894.

frequent and the os is undilated nothing can be done, and therefore the doctor may go home to finish his peaceful slumbers or to attend to his usual routine of calls.

The dilatation of the os is slow and the pains are irregular. A bag of amniotic fluid may be forced down, distending even the perineum, but when it has ruptured dilatation will be found incomplete. The os is undilated and remains *undilated*. As a rule, however, it does not long remain undilatable. All that is required to secure dilation is advancement of the presenting part.

The general management of this class of pathological labor may next be considered. Unless clear ideas upon the subject of treatment are generally diffussed, it will certainly be a long time before craniotomy becomes an obsolete operation. Time was, when it was more frequently done than the forceps operation. The time will come when even its present relative infrequency will no longer be known, and to aid in bringing this about is the chief object of the present contribution.

If the obstetrician has not informed himself fully of the relation of the child to the pelvis and of the conformation of the latter before the advent of labor, no time should be lost in doing so as soon as he sees the case. External examination, either alone or combined with internal, will disclose the exact relation of the fœtus to the parturient canal. The rectum and bladder must be empty. Much can be learned by external examination of the size of the fœtus and of the extent of the disproportion between the head and the pelvis. Ether should be given if necessary. Relaxation of the abdominal parietes is thus secured. The hand may also be passed into the vagina, although I have not often found this requisitie. The position, rate, and intensity of the fœtal heart-sounds should be noted early. Pelvimetry will afford valuable data, and it should never be omitted. I refer to instrumental and external measurements, having no experience with the recent instruments for taking the internal diameters. It must be admitted that there is a need for such, and I believe the instruments of Skutch, Hirst, and others will fill a real want.

I know of no method to differentiate between a generally contracted pelvis and a flat one other than this, and a knowledge of this fact is of the greatest practical importance. Thus a conjugate of three and a half inches, with ample transverse diameters, is a trifling affair alongside of the same conjugate with a proportionate shortening of the transverse diameters. In the latter the mechanism of labor is totally different, the treatment may differ and the prognosis is much graver. But, fortunately, the flat pelvis is the type we usually meet with. In this list it existed in all save one, or, at most, two cases. In estimating the conjugate I have limited myself to the digital method. One or two fingers are introduced into the vagina, at the same time depressing the perineum; the finger or fingers are directed upward until the round sacral promontory is reached. The other hand separates the labiæ, and with the index finger the point of the subpubic ligament is marked. The distance from this point to the tip of the finger resting upon the sacro-lumbar articulation is the diagonal conjugate. I believe a deduction of three quarters of an inch from this will give an approximate measurement of the true conjugate in most cases. I am convinced the true measurement will be underestimated more frequently than overestimated by this plan. In a true conjugate under three and a quarter inches no difficulty will be experienced in reaching the promontory with the index alone.

As to the difference in mechanism. In the generally contracted pelvis the head enters, if at all, in a state of extreme flexion. In the flat, between flexion and extension, both anterior and posterior fontanelle on about the same plane. The bi-parietal diameter adjusts itself to the so-called lateral conjugate—the line from the symphysis to the hollow of the sacral wing—and the bi-temporal diameter is in relation with the true antero-posterior diameter of the pelvis. Thus the jutting promontory of the sacrum may be passed by a head of moderate size, since the bi-temporal diameter is rarely much above three inches, and half an inch less than the bi-parietal. In addition, the head tends to enter the pelvis and pass the obstruction in a position of the lateral obliquity, the sagittal suture nearer to the promontory than to the symphysis. This peculiar mechanism is sometimes spoken of as the cause of dystocia. I have even known of attempts to force the lateral occiput to the front under this mistaken impression. It is needless to say this should not be done. The membranes

should be carefully protected; early rupture is to be avoided. If anterior obliquity of the uterus exists the patient should be placed on her back and a bandage should be firmly and evenly applied. Nothing answers better than a stout piece of muslin wide enough to extend from below the trochanters up to a level with or a little above the fundus uteri. This the obstetrician himself secures firmly by means of large safety-pins. When properly and early done, I am sure many a case of malpresentation and serious dystocia may be prevented.

The risk of infection should not be increased by repeated digital examination. After the peculiar features of the case have been learned, they are unnecessary, can do no good, and may do harm. A period of judicious expectancy is quite proper, and if the contraction is not too great and the fœtal head of average size or under, the maternal efforts may overcome the disproportion. I have seen this more than once where the conjugate has been under three and a half inches. During this time all possible means are employed to preserve the patient's strength. Easily assimilable food is to be taken, and a moderate dose of opium is often of advantage. During the expulsive stage, quinine sulphate in a single fifteen-grain dose, strong coffee, and, occasionaily, alcohilic stimulants are appropriate. Encouragement and sympathy are to be extended to the patient. From time to time the fœtal heart sounds are noted. As soon as it is evident that the woman's unaided efforts are insufficient and before the child's life is endangered, delivery must be assisted. I am convinced that the use of the forceps, and especially of the axis-traction forceps, is proper. Applied at the right time and in a proper way an average-size head may be delivered when the conjugate is three and a quarter inches. In a paper published in the *American Journal of Obstetrics*, May, 1877, I report several successful cases where the contraction was even greater. I would prefer the forceps to version because failure to deliver does not involve sacrifice of the child's life. If any doubt exists of the possibility of speedily extracting the after-coming head, version should not be done. To resort to version after the forceps have failed seems illogical since there must be greater uncertainity of being able to deliver the after-coming head quickly after a decided disproportion has been thus demonstrated. Beside this there is considerable danger of rupture of the uterus when the operation is undertaken after the waters have been drained away and when it is contracted on the fœtus. To make version and then allow the child to die in order that we may not be compelled to perforate a living child's head seems to me equally wrong. Nor do I believe that craniotomy is rendered easier when the head is last. My own views is that with forceps at the proper time, just as great a degree of disproportion, if not greater, may be overcome and with less risk to either mother or child than with version. I would not choose the latter operation unless I was sure the head could be quickly extracted.

None of the details of an aseptic major surgical operation should be omitted. As such, the application of the forceps at the superior strait is to be regarded. Undue force is not to be used. It will render the result, so far as the child is concerned, as bad as craniotomy, and for the mother worse.

I think it no exaggeration to say in advance that the management of the following case offers a marked contrast to the plan just sketched. And yet the case is but a counterpart of all the rest, with little variation in unimportant details. Its history is given without further comment.

Case VII.—In the latter part of April, 1893, I was asked to see Mrs. S., a native of Poland, who was then living at the rear end of a court not far from my residence. In this, her fourth labor, she had first the services of a midwife, who concluded after very active labor had existed over three hours, that a physician ought to be summoned. She told me she had only given ʒj of the fluid extract of ergot, and that in spite of very severe expulsive pains no advance whatever had been made in the position of the head. The doctor, a regular practitioner and a man of some obstetric experience, attempted to apply the forceps but failed, and at the end of an hour decided to call on a friend and neighbor, also a well-qualified practitioner—one who had served a term as interne in one of our largest hospitals. Together they succeeded in getting the instrument on the head, but ordinary traction efforts failed to advance it. Finally, bracing the feet against the edge of the bed, the forceps

slipped and the operator landed against the wall. At 12, midnight, it was concluded that forceps could not deliver the child. This was *eleven* hours after the membranes had ruptured, and during all this time the woman had been in very active labor, which had been in progress about twenty-four hours. However, podalic version was made, but now the real difficulty seemed to begin, and all the power two strong men could bring to bear on the delivered body failed to extract the head. Efforts at extraction were continued until the vertebral column parted and the body was torn from the head. At this juncture it was decided that the head could not be delivered unless it was first crushed, and this I was asked to do by the physician first summoned. Arriving at the house I found doctor number two had abandoned the case, the midwife alone in attendance. The remarkable advice had been given to summon an ambulance and send the woman to the Philadelphia Hospital, three miles away. The woman was then having short, rapidly succeeding pains, the uterus in tetanic contraction. Her appearance was extremely anxious, pulse frequent, and temperature above normal. The body of a very large male child lay on the bed between the thighs. The vulva was œdematous, the labiæ minora being swollen to the size of one's flattened hand. There was an offensive odor of decomposition. The head was in the uterus above the plane of the pelvic inlet and attached to the body by integument only.

After irrigating external genitalia and vagina, a catheter, introduced into the bladder with great difficulty, withdrew a few ounces of urine. The entire vagina was greatly swollen, and that there was no sloughing afterward was a matter of surprise to me. The left hand introduced into the uterus found the face looking to the right, an ear just above and behind the symphysis. The midwife held the child's body up out of the way, the physician in attendance steadied the head through the abdominal wall, and thus perforation by means of the Blot perforator was quickly made. This is a straight instrument. The brain was broken up thoroughly by passing the point of the instrument all around in the cranial cavity. Without flushing this, the Braun craniocast was quickly adjusted, the head collapsed, the opening being near the base of the cranium, and the entire operation was concluded in less than ten minutes. As the head escaped its resiliency caused air to be sucked into the perforation, and the sound emitted was something similar to that observed during the first inspiratory effort of a half drowned baby. Mistaking it for this, one of the assistants exclaimed, "And can it be possible!"

The placenta was quickly expressed, the uterus irrigated with a large amount of hot water, then with a 1:2000 bichloride of mercury solution followed by more hot water. Tha child was a male and weighed over nine pounds minus blood and brains. The diagonal conjugate, measured after delivery was exactly four inches. A liberal estimate would give three and a quarter inches for the true, the conjugata vera (8. 2 cm.). The brief details of this woman's parturient history which I learned after the delivery was completed may not be uninteresting.

Her first labor was long and difficult, and the babe, though small, was born dead. I could not find out whether instrumentally or not.

In her second pregnancy premature labor occurred at the end of the seventh month as the result of a fall, and twins were born, the first one living a few days, and the second seven months.

In the third labor the babe also perished; she was septically infected and sick in bed two months.

At 10 A. M., on the day following labor there was a normal temperature, and pulse 96. In about two weeks she was up and about, and I believe made a perfect recovery.

I have given the history of the cause in full because it is fairly representative save in a few unimportant particulars. For this reason a more detailed account of the other cases is omitted.

All were seen in consultation, the writer being called after labor had existed many hours, and, as a rule, when one plan of treatment after another had failed to effect delivery. Various oxytocics, including ergot, had been given; forceps of various designs had been applied, and failing, version had been attempted, with what success is seen in the case just detailed. It is needless to say the child's life had ceased in nearly every case. In spite even of a parturient history, that would of itself be suggestive of pelvic deformity, this was rarely suspected. Nor did the peculiar

mechanism and course of the labor at once impress themselves upon the minds of the attendants.

The contraction in none of the cases save the first was very great. The labors were insuperably obstructed by the large size of the children.

In Cases IV., V., and VIII. the greatest difficulty was met with in the extraction of the body, and this was accomplished finally by perforating the thorax, applying the cranioclast, and completing the delivery by traction on this. I am sure it would otherwise have been impossible.

And yet Case IV. has given birth to a living child since the craniotomy, without any special difficulty.

A word in ragard to Cases I. and V. The first should never have been delivered by craniotomy. An early Cæsarean section would have saved the child and given the mother a chance. When the conjugate approximates two and a half inches (0.063 m.) the difficulty to be anticipated in exacting an eight-pound child is not small. The fact that conjugate narrowing to this degree is, as a rule, associated with transverse shortening is not to be forgotten.

This was the only fatal case.

Case V., seen with Drs. De Young and Leopold, is in some respects the most unique of the entire group. Lying across the bed she was truly a mountain of flesh; her weight must have been between three and four hundred pounds. The mere making of a digital examination was exhausting. The skin covering the abdominal parietes was as hard as parchment. Subcutaneous tissues and muscles were waterlogged and infiltrated with fat. It was one of the rare instances in which abdominal palpatation would be impracticable. The amniotic fluid was in excess. There was early prolapse of the cord. The attendants had utterly exhausted themselves in their efforts to advance the head, and failing, had attempted version. Although the head was still very high and hard to reach from below, no special difficulty was experienced in perforation. The extraction was difficult, however, because of the enormous size of the child. I regret that it was not weighed. The woman made a rapid recovery. Attempts to learn

In conclusion, I want to emphasize the following points:

Insuperable obstruction of labor because of pelvic contraction is a frequent condition.

Arrest of the head at or above the pelvic brim is domparatively easy of recognition by attention to the details of external palpation, by the combined method and by the course of the labor.

Disproportion between the head and pelvis ought always to be recognlzed early in order that correct principles of treatment may be adopted.

Forceps may be employed when, after a period of judicious waiting, it is evident that the natural powers unaided are incapable of driving the head beyond the obstruction. Their use must be attended with all the care usually observed in the execution of a major surgical operation. If the disproportion is evidently very marked, leading to doubt of their successful use, an alternative should be decided on at the outset in the event of their failure. This will obviate the needless loss of valuable time.

Podalic version may be made where the membranes have not been long ruptured, and when the operator is reasonably sure of encountering no great difficulty in the extraction of the after coming head. It is of doubtful expediency after the forceps have been applied unsuccessfully.

An experience of two symphysiotomies goes far toward convincing me that this operation is destined to take high rank in the list of life-saving obstetric procedures; that it is *the alternative* when, in a contracted pelvis of moderate degree (not under 6.7 c. m.), the obstruction cannot be overcome by other means, and that it will go a long way in the direction of rendering the horrible operation of craniotomy obsolete and the Cæsaraen section under the relative indication unnecessary.

I finally want to express my belief that in assuming the management of a case of labor we, as physicians, at tha same time assume the solemn and sacred obligation of saving two lives; we dare not neglect or refuse to do anything which will conduce to this end. The social condition, whim, or desire of patients must not be allowed to swerve us from this conclusion—that the mother and her unborn child have equal claims upon us. Moreover, what is in the interest of the one is usually in the interest of the other. In our determination not to destroy the living, though unborn child, we are supported alike by the dogmatic teaching of the Church, by sound ethies, and by the latest science.

| No. | Date | Age | Pregnancy | Nationality | Pelvis | Presentation | Duration of labor | Delivery attempted by | Sex | Weight of child | Result | Remarks |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | Jan. 21, 1882 | 39 | First | Germany | Conjugata vera estimated 2½–2¾ in. | Cephalic prolapse of cord | 36 hours; waters had drained 18 hours | Forceps | M | 8 lbs. | Death on 8th day | |
| 2 | Nov. 25, 1885 | 29 | Fourth | Ireland | Conjugata vera estimated 3¼ in. S. bat | Brow | 24 hours; membranes ruptured in 18 hours | Three pairs forceps; cephalic version | M | 10 lbs. (minus brain) | Gradual and slow recovery | See American Journal of Obstetrics, vol. xx, p. 469 |
| 3 | May 30, 1888 | 18 | First | United States | Conjugata vera estimated 3¼ in. Justo minor | Vertex, R. O. I. *a.* | 24 hours; membranes ruptured in 7 hours | Wallace, Simpson, and axis-traction forceps | F | 7 lbs. | Out of bed on 12th day | |
| 4 | Nov. 5, 1891 | 22 | Second | Austria | Conjugata vera estimated 3¼ in. Justo minor | Vertex, R. O. I. | 48 hours; membranes had ruptured early | Hodge and Simpson forceps | .. | 7 lbs. | Perfect recovery | Has born a small child sice; no difficulty |
| 5 | Feb. 19, 1892 | 38 | Seventh | Russia | Normal; woman anasarcous | Prolapse of cord | 36 hours; membranes ruptured over 24 hours | Forceps, then version | M | Huge | Perfect recovery | This woman was of enormous size, and there was no descent of the head whatever; hydramnion also present |
| 6 | March 27, 1892 | 22 | First | Russia | Conjugata vera estimated 3¼ in. S. flat | Vertex, L. O. I. | 18 hours; membranes ruptured in 6 hours | Forceps and perforation | M | Large | Perfect and rapid recovery | Has since born a living child; no difficulty |
| 7 | April 29, 1893 | 28 | Fourth | Poland | Conjugata vera estimated 3¼ in. S. flat | Face | 24 hours; membranes ruptured over 12 hours | Forceps, then version | M | 9 lbs. | Recovery | Head had been torn off when I first saw the case |
| 8 | June 26, 1893 | 28 | First | United States | Conjugata vera estimated 3¼ in. S. flat | Vertex, R. O. I. *a.* | 40 hours; membranes ruptured in 6 hours | Forceps repeatedly slipped off; A. T. failed | M | 9 lbs. | Recovery | |

# TRANSLATIONS.

## A PRIMARY SARCOMA OF THE STOMACH.

The rare occurrence of this disease has induced the author, H. Westphalen, to give an accurate account of the case, together with the results from an autopsy and the microscopical examination of the specimens.

The patient, male, aged 30, was sick one year. The symptoms were principally intense pains in the epigastrium, which were independent of digestion or ingestion of food. Occasionally vomiting occurred, principally before breakfast, and consisted of mucous and acid secretions. At times there were some eructations of gas unconnected with any taste or odor. The increased salivation was an early symptom, which disappeared with time. The patient was able to feel a swelling in the epigastrium, which grew larger. Palpation in the left half of the epigastrium revealed an irregular, ill-defined swelling, movable on deep respiration. Its location was four fingers above the umbilicus, passing upwards under the left ribs, and was lost in the hepatic dullness on percussion. The resistance can be felt in the median line; the stomach is found 1½ fingers above the umbilicus; there is no dilatation present; acid reaction is not present. It was impossible at that time to decide, with certainty, to which organ this belonged. The patient was admitted on 7th of Feb. and the diagnosis remained uncertain until the 4th of March. During the four weeks there had been rapid emaciation. The author induced the patient to drink a glass of ice water and then examined the contents of the stomach one hour later. It was neutral in reaction and contained a small piece of tissue, which under the microscope was found to consist of small round neucleated cells which were partially arranged in a symmetrical manner, lying close to one another and were apparently held together by connective tissue. Glandular tissue could not be found.

On March 14th, laparotomy was performed. It was found that the greater portion of the stomach was involved in the growth and it was impossible to remove it. The patient died on March 17th.

The autopsy revealed the following: Diffuse glandular enlargement in the omentum. The stomach normal in size, its posterior portion thoroughly united to the liver and spleen. The walls of the stomach were almost universally thickened; its muscular structure almost entirely displaced by brainlike, or gelatinous substance. Numerous nodes on its inner surface seemed about to break down; one of these extending deep through the tissues to the serosa.

Microscopical examinations of these nodes uniformly show them to belong to the round-celled myxo-sarcoma.—(*Centralb. fur Chirurgie*, No. 10, 1894.)

---

SIMPLE INTEREST RULES.—Four-per-cent.—Multiply the principal by the number of days to run, separate the right-hand figure from the product, and divide by 9.

Five per cent.—Multiply by number of days and divide by 72.

Six per cent.—Multiply by number of days, separate right-hand figure and divide by 6.

Seven and three-tenths per cent.—Multiply by number of days, and double the amount so obtained. On $100 the interest is just two cents per day.

Eight per cent.—Multiply by number of days and divide by 45.

Nine per cent.—Multiply by number of days, separate right-hand figure, and divide by 4.

Ten per cent.—Multiply by number of days and divide by 36.

Twelve per cent.—Multiply by number of days, separate right-hand figure, and divide by 3.

---

AUCTIONEER.—This book, gentlemen, is especially valuable, as it contains marginal notes in the handwriting of Alexander Von Humboldt. A hundred marks offered. Going—going—gone. It is yours sir. (The autograph marginal note by the renowned scholar was as follows: "This book is not worth the paper it is printed on.)"—*Humor-Bacillen.*

TERMS:—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 14, 1894.

## EDITORIAL.

### "NO MATTER:" "NEVER MIND."

The intelligent public of this country have of late years noticed, with more or less indifference, the determined efforts of the medical profession to raise the requirements for entering that fellowship to a degree which will effectually prohibit unfit individuals assuming the important responsibilities devolving upon medical practitioners.

The differences of doctors; the bigotry of sectarians; the existence of some code of ethics peculiar to medical men, and of which the laity has no knowledge—'tis true, 'tis pity, and pity 'tis 'tis true, for it is essentially the golden rule, the demonstrations of spectre analyses and the squaring of the circle by medical experts; the colossal fortunes wrung from suffering humanity; the pharisee and the quack—all these and many other phases of medical life were quips mouldy with age when Father Time first heard them in his infancy. Handed down from sire to son, these shadows of jocose shades no longer provoke merriment, and even the most violent convulsions of the funny cartoonist can produce merely a wan smile of pity to find him "reduced to that."

But the public at large as well as scientific men are now invited to witness burlesques of such absolute absurdity and grotesque incongruity that all must perforce smile.

These farces are given under the auspices and personal supervision of the state legislatures of New York and Massachusetts.

Both exhibitions are for the benefit of persons in need of mind cure and seeking a place to apply a remedy. Mind curers, faith healers, *et id genus omne*, under the generic term of Christian Scientists—in every variety and species of this genus christianity and science are the distinguishing characteristics most constantly absent—appear as unfortunates who are clamoring for relief from oppression.

In the New York show, christian scientists appear praying that the existing laws be modified, so that "any person may

freely contract for the services of whomsoever he considers competent to alleviate suffering or prevent or heal disease, and that it shall be lawful for persons so employed to attend, treat, nurse, and endeavor to heal the employing patient, *and receive compensation therefor*, subject to the laws of the State relative to malpractice."

The humor of the situation is enhanced when we see the efforts of apostles of the immaterial to enlighten politicians who regard nothing but what can be made evident to the sense of touch. The latter expectantly listen to the demonstrations of the supremacy of mind over matter; they may conceive of the existence of mind, but evidently are skeptical as to the non-existence of matter or the discussion would abruptly close. They ask the scientist, "What is mind?" and are satisfied with the reply "No matter." Then they ask, "What is matter?" and receive the evasive reply, "Never mind." The philosophy is complete. The herald of the mind triumphant and the practical believer in the substance of things hoped for, have met on a plane common to both, which the prayer of the one and the practice of the other discloses to be—"Never mind." The hilarity of the occasion is sustained throughout by the antics of a prominent ex-member of the judicial bench that, who reaches the logical conclusion in any event, these scientists can do no harm.

The exhibition in the old "Bay State" is more elaborate and refined. When the glories of ancient Athens departed forever, the Genius of the Agora was forced to seek a living elsewhere, and for centuries tramped aimlessly up and down and to and fro upon the earth, until, yielding to the attraction of the magnetic bean-pole, it took up its permanent residence in the hub of the intellectual universe. And to-day the modern Athenians, as did the Attic gossips, "spend their time in nothing else but either to tell or to hear some new thing." In this congenial atmosphere, christian science, with the dignity acquired in the locality, solemnly protests against a bill now pending in the State Legislature. The bill provides for a Board of five examiners, appointed by the Goveanor, which shall issue a license to practice medicine in Massachusetts to all persons "without reputable degrees," on condition that they pass an examination satisfactory to the Board.

Here the interest is centered upon the star comedian. This artist has won laurels in sciences other than christian, but his present role is so unique as to secure the attention of an observer of "this busy world," (*Harper's Weekly*) who say, anent the subject:—

"Among the strongest documents on their (mind-curers) side is a long letter from Dr. William James, the Harvard professor of psychology, who says a number of things that will make lively reading for his colleagues of the medical profession. His objections to the bill are that it is too grandmotherly, and opposed to the best traditions of the State, that 'it adds but an infinitesimal degree of security to the citizens' chances of being faultlessly treated when sick' and that 'it tends to obstruct the progress of therapeutic knowledge.' His argument on his first point is that the proposed bill interferes with personal liberty. On his second point that the best doctors make mistakes, that very many doctors with medical degrees are unfit to practise, and that it is absurd to try to be so particular about doctors anyway, so long as the citizen can buy patent medicines and consume them 'at his unchartered will.' His discourse on his third point takes him into a field in which he is an expert, and is very interesting. He finds that in the treatment of diseases of the nervous system and the mind, power and learning do not necessarily go together. Remarking that the 'great Charcot is accused, and probably, correctly

of actually manufacturing new types of invalidism by his scientific performances at the Salpêtrière, while some common doctor will rescue case after case by using methods which are not medical, but pedagogic and moral,' he goes on to say:

'Of all the new agencies that our day has seen, there is but one that tends steadily to assume a more and more commanding importance, and that is the agency of the patient's mind itself. Whoever can produce effects there holds the key of the situation in a number of morbid conditions of which we do not yet know the extent, for systematic experiments in this direction are in their merest infancy. They began in Europe fifteen years ago, when the medical world so tardily admitted the facts of hypnotism to be true, and in this country they have been carried on in a much bolder and more radical fashion by all those 'mind-curers' and 'christian scientists' with whose results the public, and even the profession, are growing gradually familiar.

'I assuredly hold no brief for any of these healers, and must confess that my intellect has been unable to assimilate their theories, so far as I have heard them given. But their *facts* are patent and startling; and anything that interferes with the multiplication of these facts, and with our freest opportunity of observing and studying them, will, I believe, be a public calamity. The law now proposed will so interfere, simply because the mind-curers will not take the examinations. They return to science disdain for disdain; and nothing would please some of them better than such a taste of imprisonment as might, by the public outcry it would occasion, bring the law rattling down about the ears of the mandarins who should have enacted it.

'And whatever one may think of the narrowness of the mind-curers, their logical position is impregnable. They are proving by the most brilliant new results that the therapeutic relation may be what we can at present describe only as a relation of one person to another person; and they are consistent in resisting to the uttermost any legislation that would make 'examinable' information the root of medical virtue, and hamper the free play of personal force and affinity by mechanically imposed conditions."

An intellect unable to assimilate the theories of mind-curers and yet conclude that their logical position is impregnable may present hyperbole upon hyperbole of psychological excellence, but it lacks common sense. Cases of such metaphysical strabismus are rarely met with in the medical profession of Massachusetts.

To these phantasmagoria a most refreshing contrast is found in the current number of the *Forum*, in which appears a review of medical progress in America by a writer whose brilliancy is not that of insanity and whose opportunity for accurate information as to the status of medical science in this country, both past and present, is equal'ed by few and excelled by none. A condensed abstract of Doctor George F. Shrady's account of "American Achievements in Surgery" will be found in another column.

---

**Death of Dr. John H. Rauch.**

John H. Rauch, born September 4, 1828, in Lebanon, Pa., died March 24, 1894, at the home of his brother in the city of his nativity.

He took his doctorate in medicine at the University of Pennsylvania in 1849. In 1850 he settled in Burlington, Iowa. In 1857 he was appointed to the chair of Materia Medica in Rush Medical College, Chicago, which position he filled for three years. He was one of the organizers of the Chicago College of Pharmacy in 1859, where he taught materia medica and medical botany.

During the civil war he was brigade surgeon under General Augur, Assistant-

Medical Director of the Army of the Potomac, and Medical Director of the Gulf Department of the Nineteenth Army Corps. At the close of the war he was breveted Lieutenant-Colonel. Returning to Chicago he assisted in the reorganization of the Health Department of that city, and in 1867 was appointed Sanitary Superintendent.

During his five years of service in this office, the most notable event was the great fire, and upon him devolved the responsibility of organizing and carrying out the sanitary provisions for the great army of homeless citizens. The Illinois State Board of Health was created in 1877, and as one of its members, Dr. Rauch was elected its first president.

It was as an authority on sanitary subjects and as a practical hygienist that Dr. Rauch is best known to the medical world, but in other respects he was a scientist of no mean qualifications. A friend and pupil of Louis Agassiz, and while still living in Iowa, Dr. Rauch investigated and collected scientific material from the upper Missouri and Mississippi rivers for Professor Agassiz, and a report of his work was published in *Sillimans Journal* in 1855. He had previously published a report on the "Medical and Economic Botany of Iowa." Dr. Rauch was likewise the author of numerous monographs on subjects of sanitary science and preventive medicine. His best work as an author will be found in the eight volumes of the Illinois State Board of Health Reports.

Higher medical education owes much to Dr. Rauch. For it was very largely due to the action of the Illinois Board of Health, under the Practice of Medicine Act suggested by him, that medical institutions raised the requirements for graduation and increased the length of their teaching sessions. The general acceptance of the system of requiring a four years' graded course of study preliminary to graduation in medicine, was a crown for hard labor such as is seldom received by the laborer during life. Dr. Rauch was accorded the gratification of knowing while yet alive, that the good he had done would live after him and not be interred with his bones.

# ABSTRACTS.

## AMERICAN ACHIEVEMENTS IN SURGERY.

What may be considered as the first epoch in American surgery was the American discovery of Etherization, which was effected conjointly by Morton, Jackson and Wells. Until that time, almost within the recollection of the older practitioners of the present day, the patient who was the subject of a surgical operation suffered untold tortures of pain during its performance, instead of being, as now, rendered absolutely unconscious during the entire ordeal. When a student, the writer often heard the recitals of the experience of older men who operated before ether was known. The vivid description by Valentine Mott, of the sufferings of the poor victims, would touch the sympathy of the hardest heart. To transform such ordeals of agony into peaceful, dreamless sleep was for American surgery a triumph second to none in the long category of its other brilliant achievements. In fact, it was the starting point of all the subsequent possibilities of almost miraculous ventures.

During the late war of the Rebellion America made her next grand record by notable work upon the battle-field and in the hospital. The major operations performed during that period were commensurate with the vast number of wounded requiring surgical aid. Never before in the history of any war were so many so successfully or promptly cared for. Indeed, after the elaborate records were finished, and the results published, it was

asserted by a leading spirit in the French Academy that America held the surgical scepter of the world. Attesting the truth of this is the remarkable collection of specimens in the Army Medical Museum Washington, which is unequalled in variety and number anywhere on the globe. The elaborate histories of these silently impressive texts established new principles of procedure which were hitherto unknown to the scientific world, and gave American surgery a just recognition for originality of conception, boldness of execution and success of practice. With a training equal to any emergency, while ever ready to adopt and enlarge upon the views of others, she has not been slow in advancing on new lines and securing new triumphs. The aim has been to simplify methods, and thus give them a greater adaptability and a wider practical application. In the treatment of fractures, for instance, this is strikingly manifest in the discarding of cumbersome apparatus and the substitution of simple and more effective ones. There is hardly a bone in the body, which, when broken, has not been beneffited by the American plan of treatment. Notably prominent in this category may be mentioned fracture of the thigh and of the shafts of other long bones. It was reserved for Gurdon Buck, a former surgeon of the New York Hospital, to prove that fractures of the thigh could be most successfully and comfortably adjusted by replacing the complicated harness of straps, stretching-screws, and heavy splint braces, with the simplest form of weight-and-pulley extensions.

The demonstration of the utility of plaster-of-paris splints was likewise made by an American surgeon, the late Dr. James L. Little, who years ago brought it to its present state of perfection. The same principle of fixation was also adopted in an original way by Dr. Lewis A. Sayre, also an American, to the treatment of dis cases and deformities of the spine, by encasing the trunk in a plaster corset. The simplicity and effectiveness of this treatment are now so well established that Sayre's plaster jacket is indorsed by every surgical writer and used by every surgical practitioner. The same may be said of his original tieatment of the collar-bone, and of his methods of extension of hip diseases. The ready adaptability in the American mind to the notable advance in surgery has been shown in the matter of aseptic surgery first advocated by the distinguished Scotch surgeon, Sir Joseph Lister. During a visit to this country in 1876, Lister explained his doctrine, demonstrated its application, and proved its grand results. America was the first to feel the real impulse for good which this discovery made tangible. By its means operations became feasible which before were never dreamed of, and results were obtained which were previously beyond the reach of human endeavor.

Take the advances which have been made in abdominal surgery and for which America can claim no small share of credit. In fact, this country may be said to have originated all the wonderful possibilities connected with this special line of practice. The first one who dared to invade the abdominal region with a knife, and lay bare the vitals, was a Kentucky surgeon, Ephraim McDowell. From the time of the successful performance of that operation in 1809, for the removal of an intra-abdominal tumor a new field was opened for the mitigation of suffering and saving of life, the cultivation of which has prolonged the average human existence several thousand years. The work of McDowell, when its importance was duly appreciated, opened up a new field of practice which has widened into a distinct and almost exclusive department of surgery our work has been fully abreast with that of our transatlantic brethren. In the treatment of internal troubles by instrumentation, many other important discoveries have been made in this country during the past few years. Sims's speculum is known and used throughout Christendom. Another equally famous instrument is Bigelow's lithotrite for crushing vesical calculi, and his ingenious evacua tor for disposing of *debris*. Both of these instruments so revolutionized the old system of practice in the particular lines for which they are adapted that nothing now takes the place of the American contrivances. It is within a very short period that O'Dwyer's intubation tubes for the treatment of suffocative croup put in their claim far recognition, but they are now almost universally used in all the class of cases for which they are so eminently suitable.—*Dr. George F. Shrady, in the Forum for April.*

# SOCIETY REPORTS.

## THE LOUISVILLE CLINICAL SOCIETY.

*January 30th, 1894.*

[Stenographically Reported by C. C. Mapes, M. D.]

### CASE OF ACCIDENTAL HERNIA.

DR. P. GUNTERMANN: The case I am going to report is one which is very peculiar. It shows how quickly a person may be taken deathly sick; it shows also if the nature of the trouble is not recognized, how seriously it may reflect upon the character of the attending physician. I was called about a week ago, at midnight, to see a young man seventeen years of age, who was reported to be suffering from "cramp of the stomach." When I saw the patient I learned that he had recently gone through an attack of typhoid fever, making a very slow and tedious recovery. He had finally recovered, and for a few weeks had been in ordinarily good health. The evening I was called he had eaten a hearty supper; he attended school that night and came home feeling perfectly well. He went to bed and soon after was taken with violent pain in the stomach; directly he began to vomit and purge. His people, thinking it was an ordinary attack of something like cholera morbus, made hot applications, gave him hot whisky, etc. He continued to grow worse, and at twelve o'clock I was called in. I found him suffering with intense pain, which he located at about the pit of the stomach. I asked him if he had a rupture or ever had one, and he said, "No." I thought my first business was to relieve his intense sufferings. He had vomited a great deal and purged several times, so that the stomach and bowels must have been well emptied, and I did not think it necessary to relieve him in that way. I gave him a hypodermatic injection of ¼ grain of morphine with 1-150 grain atrophine, and then made a careful examination of his abdomen, but could discover nothing wrong. I then sat down to write a prescription, and while doing this he commenced vomiting again, and had a frightful retching attack. When this was over he said, "Oh, Doctor, there is a bone coming out of my side." I went to him and found in the left inguinal space a rupture as large as my fist. With some little difficulty it was reduced, and the pain subsided. With the reduction of the hernia, not only did pain subside in that location, but there was also entire disappearance of the pain about the stomach, and the other symptoms. I thought at the time that possibly the vomiting and the diarrhœa were influenced by a partial rupture, that the bowel had entered the internal ring, then during the last effort of vomiting it had made its exit, and after it was reduced every symptom of vomiting and purging subsided. The next day I sent the patient to a truss-maker to have a truss adjusted, and he has not had an untoward symptom since.

I want to say that if I had left the patient perhaps two minutes sooner; if the pain had not been very severe; if he had not noticed the rupture protruding at the time, by the next morning it might have developed into a very serious case of rupture, requiring an operation or some other radical measure, and the result might have been a serious reflection upon my diagnosis of his condition.

#### DISCUSSION

DR. W. H. WATHEN: Had the patient ever observed any indications of hernia preceding this attack?

DR. P. GUNTERMANN: There was not the slightest sign of a hernia until the last violent attack of retching, when it simply popped out.

DR. W. H. WATHEN: The case is very interesting, and it is now easy to understand what caused the vomiting and diarrhœa. A part of the bowel had become constricted in the internal ring, causing these troubles which the Doctor has described. Such symptoms are common in hernial protrusions. The strain produced by retching forced more of the bowel into the sac, and dilated it to such an extent as to make it perceptible both to the patient and physician; but I am inclined to the opinion that this man, if the case could be looked into carefully had a hernia before, for the reason that the sac would have been so small that I do not think it could have been enlarged so suddenly to the extent Dr. Guntermann states. We often fail to get the accurate history of troubles of this sort from patients.

DR. J. W. IRWIN: It seems to me that the pain, vomiting, and diarrhœa were all due to irritation of the bowels, and that it was a hernia from the beginning. I do not see any positive reason why the first rupture may not be large. Generally speaking they are not large, but I have seen some ruptures with history pointing clearly to that condition that were as large as a man's fist at first. But

Dr. Guntermann's report of the case shows how careful we should be in diagnosticating the cause of pain in the bowels and vomiting, in some cases.

---

GASTRIC ULCER.

DR. J. M. KRIM: Mr. V. S., aged fifty-two years; married; occupation florist; family history good; had never been sick since childhood. He commenced complaining about the middle of January, 1892, with pain in the stomach and back, which came on at intervals of two to four days; constipation marked; appetite good. This condition of affairs lasted for about two months, when pain came on at shorter intervals, more severe in character; food was vomited shortly after eating. There was loss of sleep and appetite, and loss of flesh, about ten pounds in six weeks. He had taken various remedies without benefit.

Patient consulted me early in April. Examination revealed the following: Condition very anæmic; skin flabby; pulse 90 and weak; respiration 25; temperature normal; urine normal; constipation; tired feeling, not able to work; insomnia; dull aching pain, with burning sensation in the epigastrium; pain more intense on pressure, a little to the right of the median line; stomach enlarged, pain more severe after eating, with some relief after vomiting of food; considerable thirst. Diagnosis: Gastric ulcer.

I placed him on bismuth and chloroform mixture (bismuth subnit. grs. xx, chloroform gtt. x, water $f\overline{3}ss$) to be taken every two hours until there was some relief; ordered absolute rest, with milk diet. I was called in haste about six o'clock in the evening and found the patient almost pulseless, very pale, scracely breathing, extremities cold and vomiting large quantities of blood. I applied ice to the stomach and gave it freely by the mouth. I also injected three grains of ergotin, whiskey, and aromatic spirits of ammonia, which was repeated as indicated, using warmth to the extremities. Patient rallied after eight hours of hard work, hæmatemesis ceased and he rested comfortably. The following day he had a copious tarry-looking evacuation, pulse good, no pain. The bismuth and chloroform mixture was continued and an enema was given to cleanse the bowel for rectal feeding (peptonized milk and beef). The patient did well for four days, when he had another small hemorrhage which was easily controlled. Rectal feeding and the mixture were continued. On the third day after this I resorted to stomach washing with chloroform water ($f\overline{3}j$ to Oj, twice a day for a week, then once a day for two weeks), which made the patient feel very comfortable, and continued the mixture every three to four hours, allowing small quantities of peptonized milk and beef, which was relished. Rectal feeding was discontinued and the patient kept on liquid food exclusively for three weeks, then allowed small quantities of solid food, which gave him no discomfort. He was put upon reconstructives and made a slow but uneventful recovery, gaining flesh and good color. He was under my care about three months then, having removed to tpe country. I heard no more of him until in August, 1893, when he informed me that he had been entirely well until about two months before, at which time he began to feel badly and being advised by friends to go to some watering place in Germany, he came to ask my advice. I readily approved and he left the following week, remaining abroad about two and one-half months at various watering places.

After his return I was very much astonished to note his decided emaciation and generally unfavorable appearance. He informed me that he had consulted Ewald and various other prominent practitioners abroad without any relief. He received no treatment after his return. On December 2d, 1893, he had a severe hemorrhage and died before I reached his residence.

Autopsy revealed the following: Stomach contained about a half-pint of blood; there was considerable narrowing of the pyloric orifice. About two and one-half inches from the pylorus, on the anterior surface, there was a stellar cicatrix one-half inch in length by three-quarters inch in width, with hardened edges and involving the muscular coat. At the cardiac end there was a soft mass two inches long by one inch wide, projecting about one-quarter inch above the mucous surface. In the centre of this was an irregular, apparently recent, ulcer, about one-quarter inch in diameter, in the centre of which was a small perforation. I removed a piece of the mass, had it examined, and was informed that it was a medullary cancer.

I used Hofrath Stepps' idea in regard to the cloroform and bismuth mixture. He claims that ulcers heal more rapidly under this treatment than by any other method he has tried, having had some four years' experience with the mixture.

DISCUSSION.

DR. J. W. IRWIN: The case detailed by Dr. Krim is an interesting one, and if a microscopical examination had been made it would have been still more interesting. The diagnosis in the main was correct, but the treatment of the case was less judicious in that solid food was resumed by the patient too soon. The cause of the ulcer seems to have been malignant disease of the stomach, and that was possibly the cause of the narrowing

of the pylorus. It has been my experience that gastric ulcers, even when not complicated by malignant growths or malignant formations, do not heal in three weeks or three months. It takes a much longer time. When I have seen such cases, and I have not seen a great many, I have advised the patients to remain under treatment—and very little treatment at that other than a regulation of the diet, clothing, attention to their environments, etc.—for a period of at least eighteen months before what would be called a permanent cure of these disorders can be affected.

A patient having a simple gastric ulcer came under my care six or eight years ago. The ulcer had been in existence then three years, but was not diagnosticated until after I saw the case. The patient, a lady, was very much emaciated and feeble. I sent her to the Norton Infirmary where she remained six weeks. Her diet consisted of very limited quantities of milk and cream. A satisfactory diagnosis of the case was established and she was put on the way toward recovery, When she came under my care she had frequent small hemorrhages, every time she partook of solid food it was ejected mixed with blood. The blood vomited was usually darkened by the action of the gastric juice, From the time she began to use the cream diet she had no more hemorrhages, and in the six weeks she remained in the infirmary she gained six pounds in weight. I advised that she continue the use of the milk and cream diet, the quantity to be gradually increased until it reached three and one-half quarts of milk per day. I suggested that to this quantity of milk she might add one pint of cream. She followed the advice given her for eight months, and did not depart from the instructions to avoid taking any solid food. At the end of that time, a relative visited the family and persuaded her that dieting was all nonsense and that she was starving herself to death, although she had then gained eighteen pounds in weight. This relative urged her to partake of the elaborate dinner that had been served in his honor, and she did so. In less than a half hour after eating, she became nauseated and vomited the food and about a pint of blood. She was greatly prostrated as a great deal of blood passed from the stomach into the intestines as was shown by a subsequent evacuation of the bowels. She came to Louisville on the following day and reported what she had done. I advised that she continue the milk diet. Once, about six months afterward, she ate two crackers, which was followed by vomiting mixed with blood. She then concluded that she would not again use anything but milk. While using milk and cream she had no vomiting at all I gave her no medicine of any kind. The bowel became constipated by the use of the milk and was relieved by large enemata of tepid water. She continued the milk diet for eighteen months, I then advised her to take very small quantities of baker's bread to begin with, gradually increasing the quantity, still keeping up the use of milk and cream. She had no more vomiting and no more pain after the use of food. The regular diet of mixed food, such as she had been in the habit of using before, was gradually resumed and there has been no return of the gastric ulcer in six or seven years. I heard from her a day or two ago, she is very strong and well and has gained forty-three pounds in weight from the time she first came under my care.

This case illustrates all the other cases of gastric ulcer pure and simple I have not seen a case of gastric ulcer get well in so short a time as three weeks or three months. If I understood the essayist correctly, after three weeks treatment he allowed his patient to take solid food. The point I want to make is that if it was a gastric ulcer pure and simple, the patient was ordered to resume solid food too soon. As it was, it did not make much difference, as the trouble was malignant and not a simple ulcer. Every case that I have seen unattended by malignancy, I have always considered it wise to keep under dietetic measures for about eighteen months before I could hope for a cure.

DR. P. GUNTERMANN: I have seen several cases which I thought were gastric ulcer; some of them died in the course of due time and two of them recovered. These two cases I treated by rectal feeding altogether for quite a while, then commenced gradually with liquid foods. I first gave milk diluted with lime water, making it as alkaline as possible, I gave no medicine to speak of. Some morphine was given hypodermatically for the relief of pain and, to assist the healing process, I have given lime water and carbolic acid, which I regard as one of the best antiemetic remedies that can be used.

I had one case that I diagnosticated as gastric ulcer and treated for a while; the man gained in weight: he had become strong, able to follow his occupation and my visits ceased. After a few months I was called to see him at his home. He was then quite ill; he vomited all the food taken into the stomach and had several times vomited blood. He had intermittent pain, not the continuous sharp pain that usually attends gastric ulcers. I then became a little dubious as to the nature of the trouble. Vomiting and pain continued, and in the course of time he died. I had an opportunity to make a *post-mortem* examination, and found the pylorus complete closed by an indurated mass as large as a child's head.

I do not think dilatation of the stomach is usually present in gastric ulcers. I do not believe it is according to the teaching of the best authorities to wash out the stomach in gastric ulcer.

DR. T. P. SATTERWHITE: The foregoing remarks recall to mind two cases which occured in my practice several years ago. The first was a German lady; when I saw her she was greatly emaciated, had all the appearance of cancerous cachexia, was unable to retain food, but there was no vomiting of blood. She was under my care for twelve months. I put her upon equal portions of milk and Carlsbad water and she was entirely relieved with that treatment alone. When the Carlsbad would act too freely, we substituted Vichy. She grew to be as stout as she ever was, weighing about 160 pounds.

The other case was a man who was treated in the same way at the St. Mary & Elizabeth Infirmary, he gained some flesh, and was sufficiently improved to be sent home. He died some time afterward, however, and like the case reported by Dr. Guntermann, *post mortem* examination revealed a cancerous condition of the pylorus.

DR. J. M. KRIM: The case referred to in my paper did not get well in three weeks by any means. I kept him on a liquid diet for three weeks, then allowed him a small quantity of solid food, which did not appear to give any discomfort, The stomach washing with chloroform and water was carefully carried out according to the idea of Steeps, who has had quite an extensive experience in the treatment of gastric ulcer. The chloroform and bismuth mixture is also recommended by Steeps; he claims that healing of the ulcer takes place much more rapidly under treatment by this mixture than anything else he has tried. The patient was under my care about three months, then he moved to the country; he gained in flesh while he was under treatment. I washed the stomach for about four weeks, twice a day for the first week, and after that once a day. As solid food in very limited quantities gave him no inconvenience, it was allowed, but the milk diet was continued.

Dr. Irwin evidently did not understand me correctly. I stated in my paper that the patient first commenced to complain in January, 1892, and consulted me in April of the same year. He was under my care about three months, then removed to the country and I saw no more of him until April, 1893, when he simply consulted me in reference to the advisability of his taking a trip abroad. I did not prescribe for him at this time, and he received no treatment after he returned from Germany. I was called hurriedly to see the patient, early in December, but he died before I reached him.

I firmly believe that the first trouble was simple gastric ulcer, which was entirely relieved by the treatment as stated in my report. But when he consulted me on the second occassion (in August, 1893) at the time he went to Europe, I believe the condition was cancerous. In other words the primary condition was that of a simple ulcer, and the cancerous trouble which developed later was secondary.

No history was obtained prior to the first appearance of pain (January, 1892) except that the man had always been in perfectly good health.

---

### SARCOMA OF THE TIBIA—AMPUTATION—RECURRENCE OF THE GBOWTH IN THE PERICRANIUM OVER THE PARIETAL BONE—REMOVAL —RECURRENCE.

DR. W. O. ROBERTS: I saw with Dr. Krim in December, 1898, a girl, seventeen years of age, who six months previously had her right limb amputated above the knee because of sarcomatous disease of the tibia. The wound healed nicely and she had no further trouble until November 1893, when she received, as the result of a fall, a slight bruise on the side of the head, which, however did not seem at all serious. In the course of ten days after receipt of the injury to her head, a lump began to make its appearanee. At the end of six weeks, when I saw the patient, there was a tumor as large as a man's fist situated on the left side of the head over the parietal bone. She had some numbness of the right arm and the stump of her right limb. Dr. Krim had aspirated the tumor, but nothing was secured save a little blood. We were satisfied before any operative interference was undertaken, that the growth was a sarcoma, starting, as we thought, in the pericranium. We advised operation as the only chance of prolonging life, and in the early part of December I operated at the Norton Infirmary. After having shaved the entire scalp, I made a horse-shoe flap and exposed the growth and, as we had suspected, it started from the pericranium, After removing the growth as we thought entirely, we scraped the bone which contained a carious spot, at about the size of a silver quarter, due evidently to pressure, and replaced the flap. The wound healed by first intention throughout its entire extent. The girl was sent home then, and after remaining entirely well for three weeks, the growth has recurred in about the same locality and is now developipg very rapidly; it has already attained the size it was at the time of the operation in December.

Under the microscope the growth was found to be a small round cell sarcoma.

GUAIACOL FOR REDUCTION OF TEMPERATURE.

DR. J. W. IRWIN: Some days ago I saw an account of a remedy for the reduction of the temperature in typhoid fever, which is to be applied locally. The article was a lecture delivered in the Pennsylvania Hospital by Dr. Da Costa, of Philadelphia. He reported a case of typhoid fever as a type of the disease that he had treatedby means of guaiacol. I had a case of typhoid fever, thirteen days sick, and in which the temperature was ranging from 103° F. in the morning, tn 104.°5 F. in the evening. Sponging thoroughly with cold water, ammonia, etc. several times a day did not keep the temperature below 103° F. Dr. Da Costa used in such cases guaiacol over the iliac region, applying it with a camels hair brush and then had it thoroughly rubbed in by the hand of the nurse, for from five to fifteen minutes, until the skin became saturated with it. The skin had previously been cleansed with soap and water. Then a dressing of wax paper was applied so as to hold it as long as possible in contact with the skin. He raised only one objection to its use and that was its odor. The best thing which he found to disguise the odor was oil of cloves. This I used, but the odor of the guaiacol was still quite pronounced. The application was made yesterday morning at ten o'clock. There was no change in the temperature until about eleven o'clock. When the application was made at ten o'clock the temperature was 103°F., at eleven oclock it had fallen to 101°F. At twelve o'clock it was found to be 97.5°F. and at two o'clock in the afternoon 96.5°F. There was no nervous depression whatever; there was no material change in the pulse, if any thing it grew stronger. The patient felt cheerful. The temperature remained 96.5° to 101 F. until ten o'clock at night. At three o'clock in the morning the temperature again went up to 104° F. rather suddenly. Guaiacol was again applied and an hour afterward the temperature was reduced to 98° F. and did not go above 98° F. until ten o'clock the next day. It has not been above 101° F. since that time. Two applications of guaiacol have controlled the fever in this case for twenty-six hours. How it acted I cannot tell. Dr. Da Costa thinks that it is absorbed by the skin and then finds its way to the centers which control the heat. The quantity of guaiacol used was thirty drops at each time. The author recommends thirty drops as the maximum quantity for each application, but he has used sixty drops with the result of producing too much depression of the temperature. He has used it in tuberculosis of the lungs and catarrhal pneumonia, with less effect than in typhoid fever, the temperature falling two or three degrees. He has also used it in malarial fever where the temperature went up to 104° F. and the reduction was very pronounced, it falling, if I remember correctly, to 93° F.—in this case he used from forty to sixty drops But he thought in cases where the temperature did not go above 102° or 103° F. that twenty drops would be enough. He was led to resort to this treatment, not because he disapproved of the water treatment, such as the cold bath, wet sheet, or sponging, but because he believed it to be one of the most important agents for the reduction of temperature in certain forms of typhoid fever. The water treatment, he says, has its disadvantages as moving the patient tends to produce hemorrhages of the bowels and in other ways the patient is often made worse by the bath by reason of the fact that he is not able to be moved under certain well-known conditions. In those cases where it would not be advisable to resort to the bath or wet sheet, he recommends the use of guaiacol. He thinks as a local remedy the possibilities for guaiacol are very great, although he has not yet used it in a sufficient number of cases to determine definitely. He says that guaiacol prevents the return of the high temperature very much longer than the water treatment, this of course is in favor of guaiacol as against the cold bath, wet sheet or pack. The observation I have made in this single instance is most gratifying to me and it fully agrees with the observations of so eminent authority as Dr. J. M. DaCosta.

DISCUSSION.

DR. T. P. SATTERWHITE: Would not it be better to commence with say fifteen or twenty drops of guaiacol and then increase the quantity if necessary?

DR. J. W. IRWIN: Even the reduction of temperature to 96° 5°F. in the case I have reported, was not attended by any signs of depression whatever. The pulse was not changed except that it became a little fuller and stronger. The pulse was 108 at the time the first application of guaiacol was made. The prescription was thirty drops of guaiacol and five drops of oil of cloves.

---

SUPER-FŒTATION.

DR. W. H. WATHEN: I recently attended a woman in an abortion where conception occurred in a womb containing a large fleshy mole. Two years ago, this woman placed herself under treatment for retro-version of the womb, with great enlargement, but with no adhesions or disease of the adnexa. The womb was very easily replaced in its natural position and held there by a pessary which gave relief. She became pregnant and the pessary was removed at the end of the third month. The womb then remained in position and continued to enlarge until it was the size of a three and one-half months pregnant

womb. It grew no larger and then began decreasing in size, and in six weeks had returned to its retroplaced position. Hemorrhage then began and continued for a week or ten days, when I was called to see her. She was suffering severe pain and the bleeding was profuse. The neck of the womb was dilated sufficiently to admit my finger, and I could feel a solid mass but no fœtus. The vagina was thoroughly cleansed and with a forceps I removed a fleshy mole about the size of a turkey's egg. The os uteri was imperfectly dilated, and the mole was taken away in several pieces. She recovered from the abortion and the womb was again held in place by a pessary. She menstruated regularly until about ten months ago, when she again consulted me, having all the symptoms of pregnancy. The womb continued to enlarge and at the end of three months the pessary was not needed to hold the organ in position.

At the beginning of the fourth month she had hemorrhage which continued for nearly a month. I now found that the womb had grown considerably smaller, and had again become retroverted. After a few weeks she menstruated and was regular for two months, when she again missed her menses for three months. Her womb enlarged and could be felt above the pelvis. She began bleeding again, and the womb grew smaller. The hemorrhage continued for three weeks, when her husband came for me stating that his wife was flooding and suffering severely. I found she had aborted, the embryo being about seven to nine weeks developed and in a state of decided decomposition, and the odor very offensive. The decidual membranes were removed and having cleansed her thoroughly, I expected no further trouble. Two days afterward her husband came for me and said that his wife was suffering intense pain. Before I reached the house she had expelled a hard, fleshy mole about the size of a turkey's egg, showing no signs of decomposition and having no odor, convincing me that I was correct about the first pregnancy, The embryo having died, the fluid was absorbed, and the membranes developed into a fleshy mole. The second pregnancy resulted, the embryo finally died and was expelled. The last abortion was about two months ago and the woman has recovered nicely.

DISCUSSION.

DR. T. P. SATTERWHITE: I would like to inquire if there was any menorrhagia, and what Dr. Wathen proposes to do in the case.

DR. W. H. WATHEN: There was no menorrhagia; the periods were normal. It is best to perform some kind of operation to hold the womb in position. I do not think the Alexander operation would do any good because the uterus is so large that it would stretch the round ligaments and again become retroverted. I do not believe she will consent to any operation, but I would recommend anterior ventral fixation, having first thoroughly curetted the womb and tamponed it with iodoform gauze.

DR. P. GUNTERMANN: I would like to know why, when this woman had the second abortion, and you did not find anything coming away, you did not look for that which ought to come away, the membranes, etc.

DR. W. H. WATHEN: At the second abortion the decidual membranes came away, and were so decomposed that the odor was very offensive. The placenta is very small at seven or eight weeks.

---

### The Treatment of Whooping-Cough by Bromoform.

According to the *Revue Internationale de Bibliigraphie Medicale*, Pelicer has employed bromoform with very good results in the treatment of this obstinate affection. It is a colorless liquid, produced by the action of bromine on alcohol in the presence of a base. When administered to animals by inhalation or hypodermic injection, it produces narcosis, without greatly disturbing the respiration or circulation. The dose is 1 drop for each year of the patient, given four times a day, but this dose should be increased progressively until it is taken many times a day. He has given as much as 48 drops a day during six days to a child of two years, but after this dosage he observed a general erythema, but no diarrhœa. There was increased frequency of the pulse and respiration. Bromoform diminishes the number of the attacks and their duration. Under its influence the vomiting ceases and the appetite returns. It is to be employed during a period of two or three weeks. In a number of cases he used it even longer than this.

---

### Exclusion of Daylight in the Treatment of Small-pox.

Finsen (*Hosp. Tid.*, No. 27, 1893) has made some observations on the effect of light on the skin. He referred to the good results obtained by Black and others by the exclusion of daylight in the treatment of small-pox, but argued that, as Widmark has shown that it is the ulta-violet rays which have the strong chemical action, it is not necessary to exclude the daylight, but by using red curtains tightly drawn or red window-panes, the injurious effects of the light can be prevented. The correctness of this hypothesis was proved by Svendsen, of Bergen, who last summer treated four cases of small-pox in unvaccinated patients by covering the windows with thick red wollen curtains. The patients escaped the suppurative stage; there was no rise of temperature, no œdema. The patients passed from the vesicular stage, which was slightly prolonged, into convalescence, and escaped scarring.—*British Medical Journal*, February 17, 1894.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

THE BUFFALO MEDICAL AND SURGICAL JOURNAL

for April, contains an editorial showing the result of changing the water supply from the Niagara river to the inlet, communicating with the harbor, and pumping from an old unused reservoir. This was done during the month of February, and during the first week of March two-hundred new cases of typhoid fever were reported, while previous to this date the number reported conformed to that of other years.

A significant fact is, that one part of the city escaped with only one case, and that part had the same variety of inhabitants, homes, manner of living, etc., as the rest of the city except that its water supply was independent and came from natural springs.

In the same journal Dr. James F. W. Ross reports a case of

**Suppurating Myoma of the Uterine Wall.**

for which he operated five weeks after confinement. The growth proved to be an intramural fibroid, about the size of a child's head, and left a very perceptible cavity in the uterine wall, palpable through the abdomen.

The case is reported because the wall at the point of attachment, extending from the fundus to the internal os, was left so exceedingly thin that it did not seem possible that pregnancy could terminate naturally at any future time, and the author has lately heard of the safe delivery of twins.

Dr. I: N. Love writes about

**Neurasthenia,**

which he believes to be a term often misapplied, and thinks nerve weariness is quite different from nerve exhaustion, and generally due to over eating and constipation; perhaps, combined with anxiety and laziness. Proper regulation of the diet, free purgation for a week or so, properly graded exercise, a greater supply of fresh air, and possibly the relief of peripheral irritation, would, the author, thinks, cure many attacks of so-called nervous exhaustion.

Dr. Herman Mynter gives some clinical reports of very interesting cases which have required

**Trephining.**

In one he was able to replace a one-and-one quarter inch circle of bone, and in several he placed irregular fragments in the opening, and prevented thereby the union of scalp and dura mater, suppuration compelling the removal of these nuclei in only one instance.

On several occasions the author attempted the use of gold leaf to close the opening in the skull, but irritation and pain always forced its removal; plates of celluloid were free from this objection.

The author considers the use of antiseptics, even in exceedingly weak solution, very objectionable in brain surgery. Sterilized water, has in his experience given perfect satisfaction, whereas, the chemical solutions did not.

The cases cited comprise subdural hemorrhage with aphasia and paresis, abscess of the brain, and traumatic epilepsy; all ended in recovery both from the operation, and the cause of the operation.

Dr. Edward B. Angell reports the result of an autopsy on a woman of thirty-four years, who when five years old suffered a

**Sudden Right Hemiplegia During Convalescence from Scarlet Fever.**

Recovery occurred from the hemipleyia, but the right arm and hand never fully developed. Two and one half years before her death symptoms of cerebellar tumor appeared, but no operation was performed.

The autopsy revealed an encapsulated gliosarcoma two ounces in weight, spherical, lying between the right cerebellar hemisphere, the right temporosphenoidal, and the occipital lobes, and pressing on the corpora quadrigemina.

The right crus cerebri, the pons, and the medulla were pressed on by the growth. The left cerebral hemisphere contained a large cyst, the sequel of the trouble in childhood, and was one-fifth smaller than its fellow, while the right side seemed to have the convolutions, sulci and gray matter all developed, to take the place of the deformed left.

The right cerebellum was in keeping with the left cerebral hemisphere, confirming the theory of their development in unison.

The author describes also, the gradual learning to speak again, and the failure to develop the muscular system so as to dance, or even run easily.

IN THE JOURNAL OF NERVOUS AND MENTAL DISEASES

for March, Dr. E. M. Green reports a case of

**Hysterectomy for Procidentia.**

The patient was fifty years of age, the subject of chronic mania, and had been in the asylum for ten years. During all of this time she was noisy, filthy, destructive, and even by the use of hypnotics obtained only a few hours' sleep.

She had suffered for some time from complete prolapse of the uterus, had a cystocele and rectocele and suffered much from loss of blood from vaginal ulcers.

Attempts to return the uterus and keep it in position failed on account of the patient's interference; hysterectomy was performed, therefore, under very unfavorable conditions, but the patient nevertheless was up at the end of six weeks looking much better.

In about two months her habits and mental condition began a rapid improvement. No recurrence of cystocele or rectocele took place, and the author states that she is now a well behaved patient and has not required a hypnotic for about five months.

In the same number Scheinmann is quoted from the *Berl. Klin Wochensch.*, stating that a common, and often unsuspected, cause of persistent headache is some nasal trouble, which being relieved puts an end to the headache.

He declares headache to be frequently the only early symptom of severe nasal disorders, that the demonstration of nasal origin permits a favorable prognosis, that in all cases of headache of unknown origin careful examination of the nose is required, and that the extistence of neurasthenia does not exclude a local cause for the headache.

---

IN THE SANITARIAN

for March, is an article by Fraenkel (from the *Deut. Med. Woch.*) relative to the

**Effect of Thymus Cultures of Eberts' Bacillus,**

rendering animals free from infection by this disease. Fifty-seven cases of typhoid fever in man were treated as follows: Thymus cultures, proved to be sterile by experiment, were heated to 63° (R.) and 0.5 c. c. injected into the iliac region, (afterward the glutei were found preferable).

No change was noted on the first day; on the second the dose was doubled, and caused rise of temperature and shivering. On the third day the temperature fell, and again on the fourth; but if the treatment were not confined it would now rise. The temperature was used as the guide for treatment, and when there was no rise, injections were given at intervals of two days, an increase of 1 c. c. being made each time. The fever became intermittent, and in a short time there was a pyrexia. With the fall there was profuse diuresis and sweating, and a lessening of the diarrhœa.

The patients seemed convalescent, while still having enlarged spleen and the rose-colored spots, and fourteen or sixteen days after defervescence were able to be up. The treatment was successful in relapses, and produced a uniformity and rapid improvement, not to be obtained by other means.

To settle the question of sterilized culture of micro-organisms, having no connection with the disease, favorably affecting its course, a few were tried, and seemed again to act favorably. The culture medium was prepared from the thymus here also.

---

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES

for April, contains an interesting paper by Dr. J. M. DaCosta, on

**Cardiac Asthenia, or Heart-Exhaustion,**

meaning by this that condition in which there is for a long period habitual feeble action of the heart, and where this constitutes the essential and only appreciable disorder. This heart-feebleness or heart-exhaustion comes, he says, from two causes: it is due either to nervous failure or to a weak heart muscle; in some instances to a combination of both.

The affection generally manifests itself in those whose nervous system has been strained by worry or overwork. It shows itself frequently by a veritable and sudden cardiac collapse, though the causes that have led to this become apparent enough when inquired into, and there have been warning signs. The patient is obliged to stay in bed; all attempts at sitting up produce a sense of swooning and vanishing pulse, or there is actual fainting from time to time. The heart's action is feeble, the pulse is very small and compressible, and generally increased in frequency; there is a sense of uneasiness in the cardiac region, but very rarely actual pain; the extremities and the nose and ears are cold; the general temperature is below the normal. The capillary circulation is poor, the skin pale, occasionally injected or flushed; sweating is the exception. The breathing is conspicuously unaltered, although there may be a sense of oppression. The reflexes are unimpaired or sluggish. The appetite is poor, though there are no marked gastric symptoms; the bowels are constipated. Insomnia may be complained of; apprehension and low spiritis are very common. From this state of depression and disturbed circulation the patient rallies but slowly. It is one or two months before he can sit up without inclination to faintness, and months more before he recovers. The course of the disease is as markedly chronic as the onset has been markedly rapid.

The heart's action is mostly accelerated, but not irregular. It is very variable, always rises markedly after meals, and is influenced by the slightest exertion. The physical signs of the heart disorder are very significant. There is no increased percussion dullness, the impulse is feeble, difficult to find, not diffuse. The first sound is short, lacking in volume, and may be obscure or short and valvular; the second is not accentuated. Rarely there may be functional apex murmurs of dynamic origin, and these murmurs may be brought out by suddenly closing the hand tightly. A sensitiveness to touch in the cardiac region is at times noticed.

The author is inclined to attribute the cardiac weakness more immediately to disturbances in the cardiac ganglia than in the centres in the medulla and to the disordered inhibitory influence of the vagus, though he grants that the central nervous system is affected.

In the asthenic nervous heart the prognosis is good. Under treatment and in time they all recover. While there is danger from so-called heart failure the author has never met with an instance. With a heart weak from muscular weakness the same is not true, the author reporting a case in which with only a very moderate amount of bronchitis, a sudden and unlooked-for fatal collapse occurred.

For the cases of the asthenic weak heart, rest in bed is essential, and when the patients are able to sit up, nothing does as much good as graduated shower baths. Massage is useful at a later stage of treatment. Where the weak heart depends on muscular weakness, massage and Swedish movements can be resorted to from the beginning. From Swedish movements that are especially adapted to promote the flow of blood and to strengthen the heart, the author has seen great good. The food should always be as nutritious as possible, taken as frequently and in amount as large as the digestion will tolerate, and stimulants have often to be resorted to. The tendency to constipation should be remedied by diet and light laxatives.

Among drugs strychnine stands pre-eminent. It should be given in doses of one-thirtieth of a grain, three times a day, and continued for some time. Iron is only needed to combat any complicating anæmia and its tendency to constipate makes it a remedy of doubtful advantage. Arsenic in the nervous heart comes next to strychnia. Its action cannot be explained by its removing anæmia, for it proves to be valuable where the blood-count shows this not to exist. Of the so-called heart tonics, digitalis is the best, but it is not the certain remedy that might be supposed. When it is used the patient should be kept in bed. Adonidin and chloride of barium have been of good service at times; cactus and convalaria have been disappointing. Caffiene and cocaine are both valuable, but their action cannot be kept up; from cocaine there is the danger of establishing the cocaine habit. It is, however, very serviceable during urgent symptoms of failing heart. Nitroglycerin is not of much avail, except there be cardiac pain, or in combination with remedies like digitalis, which act more distinctly on the force of the heart. Bromides, valerian, and opium ought to be left to meet certain special indications of nervous disturbance.

In the paper is the report of several cases of this interesting condition observed by the author.

Dr. Charles W. Allen contributes a paper on

**Syphilis of the Epididymis.**

The epididymis, according to the author's observations, is capable of suffering by itself, and not infrequently is affected independently of the testis proper, not only in the early consecutive period of syphilis, but in all stages of the disease and sometimes quite late. In what is termed commonly syphilitic testicle, the epididymis is affected in perhaps one-third of the cases, and the possibility of the organ remaining enlarged after a mild grade of orchitis which has disappeared should be remembered to obviate a possible source of error in diagnosis. The early diffuse syphilis of the epididymis, or syphilitic epididymitis proper, is usually confined to the globus major, though cases have been reported in which the tail alone has been inflamed, and often the body suffers too. The enlargement may be either rounded or irregularly square or angular, and often not much larger than an American chestnut. There appears to be a decided tendency for both epididymes to suffer coincidently or one after the other. If other diagnostic features are not sufficient, the fact that the infiltration entirely and quite promptly disappears under anti-syphilitic treatment makes its nature clear. Sequellæ are usually absent, while after gonorrhœal epididymitis fibrious remains are apt to show themselves for a long time, especially about the tail.

The author cautions however, that a slight improvement under the iodides must not have too much weight given to it, as the same temporary improvement may take place in tuberculosis of the epididymis. Where fibrous changes have taken place we cannot hope for a return to normal form and size; and when pressure has been exerted, surrounding, and perhaps parenchymatous deposits may result; but, aside from such changes, the iodides should affect a cure.

Several cases are reported by the author.

William Thomas Corlett, M. D., L. R. C. P., Lond., discusses

**Pemphigus:**

its clinical varieties and treatment. In the treatment he states that he has never observed the slightest benefit from arsenic and he is forced to the conclusion that as yet we have no trustworthy specific for pemphigus. The internal treatment should be conducted along the lines of general therapeutics. Food should be selected which is easily digested, although possessing the proper elements for proper nutrition, such as milk, eggs, &c. In pemphigus, above all diseases, tonics are indicated. Iron and arsenic, the latter in small tonic doses, and, in selected cases, cod-liver oil, will afford the best means at command. Locally the general hygienic environment should be looked after, fresh air and sunlight should never be forgotten, and, in an epidemic, isolation and disinfection, such as recommended for smallpox and erysipelas. Then the blebs should be punctured and the sac washed out with some bland disinfectant, such as the saturated solution of boric acid. This is followed by some application of a bland, soothing nature. The author finds the continuous water bath in use in Germany, of great service but difficult of application in private practice. Of lotions, the glycerole of tannin has given the most marked benefit. It may be used in the strength of one part of the glycerole of tannin to three of distilled hamamelis or water. This strength may be increased to equal parts of the glycerole of tannin and camphor-water. When the eruption is limited to small areas, the glycerole of the subacetate of lead and glycerine, of each one ounce added to a pint of water, often acts admirably. When itching is present resorcin or carbolic acid are the best agents we possess for allaying it. These are used in the form of lotions, one drachm to four ounces of water. Sometimes cloths saturated with a bland oil prove most grateful to the patient. During convalescence, especially in the exfoliative form, some emollient, such as vaseline or the benzoated zinc ointment, is to be recommended.

Dr. George Dock writes of

**Pernicious Malarial Fever,**

reporting a fatal case. The parasites encountered in this case seem to be identical with those described by Marchiafava and Celli as the small plasmodium, or the parasite of summer and autumn in Rome. They agree, so far as one can determine by descriptions and without actual comparisons, in the size of the fully developed organism, their short cycle (about twenty-four hours), their lively motion, and the peculiarities of the spore figure and of the pigment. The growth of the parasites was checked almost completely very soon after the patient's death. The author cannot say whether this was due to lack of oxygen or to altered temperature, or to other causes.

The paper is illustrated with half-tone cuts of the microscopical appearances of the blood and splenic juice.

John Croft, F.R.C.S., England, contributes a paper on

**The Mortality after Operations for Strangulated Hernia; the Treatment of Gangrenous Intestine, and the Radical Cure of Hernia.**

In his own experience the mortality of the operation has been reduced from 50 per cent. in pre-antiseptic times to 29½ per cent. at present. The author discusses the questions of artificial anus, and primary resection and suture, deciding that no hard and fast rule can govern these cases, but each must be decided on its own merits. In regard to removing the omentum in cases of strangulated hernia, the author believes it wiser to cut off the omentum antiseptically than to run the risk of bruising it and even tearing it by pushing it back through a relatively narrow orifice. When in doubt, remove it antiseptically is a good rule.

In answer to the question as to whether a radical cure should be attempted in operations for radical hernia, he says that all patients suffering from strangulated hernia should be given the advantage of a radical cure; and he goes farther and says that all patients suffering from obstructed hernia should be advised to submit to early operation and radical cure. He attaches great importance to placing the ligature high up on the neck of the sac. In many cases of inguinal hernia he fastened one end of the sac-ligatures to the internal oblique and inner pillar of the ring, but he doubts the value of it. In almost all instances of inguinal hernia he brought together the pillars of the ring by sutures, at the same time avoiding any pressure on the constituents of the spermatic cord. For sutures he gives the preference to silk as more durable and reliable.

The remaining papers in this issue are: "A Case of Non-hereditary Friedreich's Disease," by Hector W. G. Mackenzie, M.A., M.D.

"A Case of Tuberculosis of the Skin Simulating Lupus Erythematosus and Erythematoid Lupus Vulgaris," by W. A. Hardaway, M.D.

"A Case of Locomotor Ataxia Beginning in the Arms," by J. K. Mitchell, M.D.

"A Case of Fracture and Dislocation of the Second Lumbar Vertebra, with Operation," by Richard C. Newton, M.D. The patient died five and one-half days after operation. Dr. Henry Power presents a report of the microscopical examination of the spinal cord.

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## THERAPEUTICS.

### A New Anti-Neuralgic and Anti-Rheumatic.

In an article in the *Deut. Med. Woch.*, No. 18, 1893, Dr. Edmund Koch writes as follows: "All reports speak in satisfactory terms regarding the prompt action obtained with Salophen in acute articular rheumatism. In doses of three to five grains or at most six grains per day it rapidly diminished the fever pains and swelling; and in laudatory terms it is pointed out that in this affection it has the same action as Salicylate of Soda and Salol, but it is preferable to them on account of its agreeable taste and the absence of disagreeable after effects. In older cases, as well as those which have become chronic and have persisted for many years, and in the arthritis deformans it is frequently ineffective, but may be alternated with advantage with other remedies the more so since it sometimes relieves the pains at least the beginning. The dose here varies from 4 to 6 grms per day. The chief domain of Salophen, however, is the large field of nervous diseases of every kind; neuralgias, such as sciatica, pleurodynia, intercostal neuralgia, neuritis, hemicrania, and odontalgias as well as other painful affections. In mild cases, a dose of 0.75 grms is effective; in the more severe, larger doses up to 3 or 4 grms must of course be employed. Only a few cases of nervous diseases fail to yield to this treatment.

The remedy is best administered in the form of powder in doses of 0.75 grms. Owing to its tastelessness it is readily taken in doses of 3 to 5 grms, which are amply sufficient. It is devoid of any after effects.

### Pental.

Phillip (*Zeitshrift f. Kinderheilk.*, Bd. iii., 4 1893) states that during the preceding twelve months chloroform and pental were the only anæsthetics used in the Kaiser Fredrich Chil-

dren's hospital, Berlin, local anodynes having been found impracticable in the case of children. The following were found to be the principal advantages of pental: Extraordinarily rapid narcosis; rarity of a period of excitement, which, if present, ceased with absolute narcosis; immediate recovery of consciousness after removal of the mass; and absence of any unpleasant after-effects such as are caused by chloroform. No action on the heart was ever observed, but in some patients arrest of respiration and cyanosis occasionally appeared, when removal of the mask sufficed to restore the natural color. The author attributes the cyanosis, not to any toxic action on the respiratory centre, but to tonic contraction of the diaphram and glottis. In twenty-one cases the urine was subsequently examined for albumin, but not only was a trace found, which disappeared on the third day; this occurred in a tuberculous child after a prolonged operation. The majority of the operations lasted from ten to thirty minutes, from thirty to sixty cubic centimetres of pental being required. In conclusion, judging by one thousand narcoses, pental is, with certain exceptions, always able to replace chloroform, being, moreover, less dangerous and without after effects. In the above-named hospital pental is now looked upon as an indispensable drug, but during its use all precautions should be taken as when administering chloroform.—*British Medical Journal*, February 17, 1894.

## MEDICINE

### Etiology of Bronchitis.

Marfan and Claisse (*Boston Medical and Surgical Journal*) place bronchitis among the germ diseases. They claim that by the sudden chilling of the cutaneous surface, and especially when the body has been overheated and is perspiring, the blood is chilled and carried to the internal organs, causing such changes that the microbes which commonly infest the upper air passages and bronchi find a favorable condition for their multiplication and pathological operations. Under ordinary conditions the leucocytes are able to control the invading hosts, but the congestion (plus something else as yet not understood) produced by the sudden chilling of the surface places the organism in a state of lessened resistance, and the enemy enters and possesses the country for a period varying from two to five weeks.—*Amer. Pract. and News.*

### Ergot in The Treatment of Periodical Neuralgias.

Dr. William H. Thompson read a paper on this subject, in which he gave the histories of a number of cases of severe periodical neuralgias in which the symptoms had been promptly relieved by the use of ergot in large doses. In all of these cases the disease had been of long standing, and the usual remedies had been employed without avail. Dr. Thompson said his method of administering the ergot in migraine was as follows: The fluid extract of the drug was employed, combined with an equal quanity of elixir of cinchona, to obviate the tendency to cause nausea. Two drachms of this mixture were to be taken in water as soon as the premonitory symptoms of the headache were noticed, and the patient was advised to lie down and keep very quiet. If, after an hour, the headache continued, a second similar dose was taken, and then a third in another hour if necessary. As nausea was such a general accompaniment of this affection, it was provided that if either of the doses be vomited it should then be taken in an enema of two ounces of water. This medication, the speaker said, rarely failed to arrest the attacks, even in long-standing cases, and with a preventive course of intestinal antisepsis in the intervals.—*N. Y. Med. Jour.*

### The Therapeutics of Oxygen.

Dr. A. W. Catlin, of Brooklyn, read a paper in which he stated that the therapeutic use of oxygen was of very recent date. The treatment of disease by natural means was proving more and more efficacious as experience increased. Oxygen was a distinct remedial agent—one that should not be left untried until the patient was *in extremis*. It was the surest and most satisfactory stimulant that we possessed, and was applicable to many conditions. In profound shock, from whatever cause, it had been found to exercise a reviving effect. It was taken up quickly by the blood, but its chief value was in its effect upon the nerve centers, upon which it exercised a quieting and soothing effect. In hemorrhage from typhoid fever he had seen relief in many cases. It would produce sleep, favor assimilation, and shorten the period of convalescence of typhoid fever. No agent was so well tolerated or so useful in restoring the equipoise of the physical condition. In cases of childbirth, pneumonia, bronchitis, and other exhausting diseases, the use of oxygen was indicated, and it should not be given late but early.—*N. Y. Med. Jour.*

### The Treatment of Pregnancy Complicated by Heart Disease.

Dr. Geo. G. Sears in a paper upon this subject summarizes his conclusions as follows:

1. That many women with valvular disease, even when situated at the mitral orifice, pass through repeated pregnancies without the development of serious symptoms, and at times without suspecting that they are victims of such disease.

2. That as miscarriages are very frequent, and the chances of the child's surviving more than a few years are doubtful, if the mother's condition during pregnancy has been serious, the probable fate of the latter should take so much more prominence in deciding the question of abortion.

3. That the necessity of inducing abortion is very probable if grave symptoms have appeared during the early months, or are present with an advancing lesion, or if there is a

history of extreme danger in the preceding pregnancy.

4. That if the necessity for an abortion becomes apparent, the sooner it is done the better, while the fetus is still small and the expulsive force chiefly furnished by the uterus.

5. That the hope that relief may be given when the case has become desperate by inducing abortion is delusive, as it is possible that it only increases the danger.

6. That marriage should be forbidden except, perhaps, in very unusual cases, to women suffering from cardiac disease—*Boston Med. and Surg. Jour.*

---

### On the use of Antiseptics in the Treatment of Typhoid Fever.

Dr. E. N. Nason, in a paper read before the Birmingham branch of the British Medical Association under the above caption states that the ideal antiseptic in typhoid fever which has yet to be discovered must fulfil the following conditions.

1. It must be innocuous to the patient.

2. It must be destructive of micro-organismal action, without interfering with the normal digestive ferments.

3. It must reach the small intestine while

4. It must be capable of absorption from the intestines, and not a completely insoluble substance.

still operative.

He employes as an antiseptic a preparation which he calls chlorinated quinine, and which is prepared in the following way as suggested by Dr. Burney Yeo:

Into a 12-oz. bottle place about 30 grs. of chlorate of potassum, and upon this pour 40 grains of strong hydrochloric acid. A yellowish-green gas is given off, which should be allowed to accummulate in the bottle, then add water, an ounce or so at a time, shaking well as the water is added. The gas dissolves in water forming a yellowish-green solution and smelling strongly of chlorine. This solution contains free chlorine, peroxide of chlorine, protoxile of chlorine, and some unde-composed chlorate of potassium. To this is added 24 grs. of quinine, and a little syrup of orange. The mixture should be kept in a cool, dark place as it decomposes under the influence of a bright light. An ounce of this should be given every 3 or 4 hours to an adult, for children a proportionately small dose. While not contending that this particular mixture is necessarily the best the form of antiseptic to be used, he recommends it, and claims the following advantages over the expectant method from its use.

First those which may be constantly expected:

1. Reduction of temperature to a greater or less extent.

2. Improvement in condition of tongue and mouth.

3. Reduction of fetor of stools.

4. Improvement in general appearance and condition, with a greater sense of well being, and less hebetude.

5. Prevention of excessive fermentation or putrefactive changes in intestine with consequent tympanites.

Second those occuring with greater frequency than ordinarily:

1. Abortive attacks.
2. Freedom from complications.
3. Shortened febrile period.
4. More rapid convalescence.
5. Low mortality.

---

## ARMY AND NAVY.

### U. S. ARMY FROM APRIL 1, 1894, TO APRIL 7, 1894.

Captain Edward C. Carter, Assistant Surgeon, will proceed at once to Fort Spokane, Washington, and report to the commanding officer for temporary duty.

Leave of absence for twenty-one (21) days, to take effect on or about April 14, 1894, is granted Major Charles L. Heizmann, Surgeon U. S. Army.

The following named officers are detailed to represent the Medical Department of the Army as delegates to the Association of Military Surgeons of the United States, to meet in Washington, May 1, 1894: Lieut. Col. William H. Forwood, Deputy Surgeon General; Major Robert M. O'Reilly, Surgeon; Major Joseph K. Corson, Surgeon; Major Walter Reed, Surgeon; Captain John L. Phillips, Assistant Surgeon; Captain G. L. Edie, Assistant Surgeon.

First Lieut. Henry D. Snyder, Assistant Surgeon, is relieved from duty at Fort Reno, Oklahoma Territory, and ordered to Fort Du Chesne, Utah, for duty at post, relieving Captain Samuel Q. Robinson, Assistant Surgeon.

Captain Robinson, on being relieved by Lieutenant Snyder, will report in person to the commanding Officer, David's Island, New York, for duty at that post.

Major Peter J. A. Cleary, Surgeon, will be relieved from duty at Fort McPherson, Georgia, by the commanding officer of that post, on the receipt by him of this order, and will report in person to the commanding officer, Fort Custer, Montana, for duty at that post.

First Lieut. Edward L. Munson, Assistant Surgeon, will proceed without delay to Camp Merritt, Montana, and report to the commanding officer, for temporary duty at that post.

First Lieut. Charles F. Kieffer, Assistant Surgeon, having reported at Headquarters Dept. Dakota, is assigned to temporary duty at St. Paul, Minn., and will report to the Medical Director of the Department for instructions.

### THE ORIGIN AND CAUSES OF PYREXIA IN TYPHOID FEVER.

J. WELLINGTON BYERS, M. D., Charlotte, N. C.

The factor of high temperature with its concomitants of tissue waste, perverted metabolism, and cell inertia, is very generally conceded to furnish the leading indications for treatment in typhoid fever. Indeed antipyresis in some form or other is now regarded as absolutely essential to a rational and successful management of this disorder.

This is substantiated by the fact that a large proportion of modern methods employed recognize and seek to modify and combat this particular symptom. And it may be added, that experience shows that they are all severally successful *pari passu* with their capacity to control harmlessly this most formidable feature. Such being true it is highly proper that we should possess a real and definite knowledge of the origin and causes of the pyrexia in typhoid, in order that they may be attacked and met in an intelligent manner. To accomplish this, it will be necessary to transform some of the current teachings concerning the pathologic conditions ordinarily associated with this disease, and to break away from some misconceptions in regard to what has hitherto been accepted as part of its true clinical history.

With this end in view, we may separate the lesions into two groups, namely, the essential, and the accessory or accidental, lesions. In the first division, we place changes arising from the local action of the bacilli and their concentrated toxines upon the glands and lymphatic structures of the abdomen, together with the more remote effects of the same upon the body, temperature and general nutrition. These effects are the direct result of the bacilli and their products, and constitute the only specific or essential lesions in typhoid fever. In the second group, we have the accessory or accidental lesions, some of which are sometimes present, sometimes absent, sometimes this one and sometimes that one, depending upon the treatment pursued, the patient, the stage of the disease, and other contingencies. Prominent among the lesions of this latter class stands gastro intestinal catarrh and its associated phenomena of perverted digestive and assimilative functions, leading in turn to putrefactive and fermentative changes, and as a final result the absorption of various toxic substances into the general circulation, causing disturbances of temperature, cell destruction, innervation and symptoms of profound constitutional character. As is obvious these latter changes do not emanate from the specific lesions already enumerated, but are accessory and independent factors in the complex result produced in the organism.

The same fact applies to another class of lesions which have long been held to be a part of the true pathology of this disease. I allude to the ulceration that follows in the second and third week and causes such serious symptoms. These glands ulcerate and break down, causing hemorrhage and septic fever, not as a result of the effect of the specific bacilli *per se*, but from the fact that their vitality is lowered by the presence of the latter and the pus-producing cocci are enabled to engraft themselves

upon a tissue which, before, would have resisted them successfully. These lesions of the second class are in no way peculiar to typhoid fever, nor do they constitute essential factors in its true clinical phenomena, but, to the contrary, they are associated with a number of acute febrile infectious diseases, which lower resistance and invite the encroachment of new factors in the form of accidental lesions. The only constant and essential lesion of typhoid fever is the infiltrated non-suppurative inflammation of the solitary and agminated glands of the intestines, associated with a febrile reaction of 100° F., and slight disturbances of the general nutrition of the organism. Everything else, in the light of what has been written, may be regarded as non-specific in character, not peculiar to typhoid fever, but associated phenomena referable to other causes.

Interpreted from this standpoint the question of treatment resolves itself into that of ascertaining exactly what importance, and how much value is to be attached to each of these several factors as co-operants in the complex result of excessive heat. In the present state of our knowledge it is impossible to say absolutely, how much is attributable to each. Judging, however, from the marked and rapid reduction of temperature that usually follows the exhibition of substances capable of evacuating the contents of the bowel and arresting putrefactive changes transpiring therein, we are warranted in concluding that the larger proportion of the pyrexia is directly due to these causes and not as is generally supposed, to the product of the specific lesions or the bacilli and the pathologic changes in the glands. In an experience with sixty cases of typhoid fever I have put to test the principles here announced and I have demonstrated that they are true beyond peradventure of a doubt.

Starting with the idea that the pyrexia is the product of a mixed infection, complex in character and largely the result of fermentation and putrefaction in the intestinal canal, I have used agents qualified to arrest decomposition and keep the bowel comparatively empty. By doing this the temperature has been kept exceedingly low and dangerous symptoms entirely avoided. My plan has been to administer from the beginning of the attack, the sixth of a grain of calomel combined with sugar and soda, every hour until the bowel has been freely evacuated. This is repeated every day or every other day during the entire illness unless contra-indications supervene, such as excessive purging, prostration and nausea—which I may add are very rare—when the drug is stopped for a while. When calomel is used in this way, my experience shows that the functions of the gastro-intestinal tract are speedily resumed and kept in a physiological condition, the tongue cleans off and becomes moist, tympany is absent, the fever declines at once and remains low, scarcely ever beyond 102° F., and the patient presents an array of symptoms which every way indicate that he is better. By pursuing this method the fever rarely exceeded 102° F., and when it did, it was invariably found to be the result of retained and decomposed food substances, and speedily declined upon their removal by the medicine. When calomel is used in this way there is little or no danger from hyper-catharsis or salivation, nor does it induce asthenic conditions. To the contrary, it is a general cell stimulant, promotes glandular action and opens up the emunctories in the best possible manner, and in this way eliminates the morbid substances from the internal tissues as well as from the canal.

As a remedy for the routine treatment of typhoid fever, supplemented by such other agencies as the individuality of each case may demand when the accessory lesions predominate, calomel will demonstrate its utility beyond question. That it will prevent or lessen a considerable part of the pyrexia that usually accompanies this disease, unless treated by direct antipyretics which do not reach the real seat and cause of the former, I am quite certain. By the use of the calomel we not only avoid the high temperature, conserve the vital resistance of the organism and bring about a speedy convalescence, but the appetite and digestion remain good, the stupor and delirium of toxæmia are altogether absent, and the ulceration, hemorrhage and perforation so much dreaded in this disease do not occur and the most potent causes of mortality are removed.

In a recent paper by W. B. Thistle, of Toronto, Canada (*N. Y. Med. Record*, Vol. 45, No. 10), is given the results of this eliminative and antiseptic treatment

in forty consecutive cases of typhoid fever. There were no deaths or unfavorable symptoms in any case. Average attainment of normal temperature on the twelfth day and entrance on convalescence. No hemorrhage. No perforation. Tympanites was present in only one case, but quickly disappeared. In fifteen of his cases the characteristic rash occurred showing the diagnosis to be correct.

For a safe, ancient and successful remedy, controlling and preventing as it does the most serious symptoms in this disease, I can commend calomel in the manner set forth above, as the most efficient of remedies in typhoid fever.

## A CASE OF TYPHOID FEVER, WITH SEVERAL RELAPSES.

MARY H. THOMPSON, M. D.,* CHICAGO.

This case of typhoid fever was to me exceptional, because of its four periods of fever within eight weeks, and its many complications, some co-existing at the same time, and others arising at several different times.

The case was attended at its beginning (during my absence from the city), by Dr. Annette Richard, who invited me to take charge of it when I returned, as it was in a family where I had had the medical care for several years.

July 30, Dr. Richards was called to Mrs. P., who was forty-nine years of age, and had been a very healthy woman up to about five months previous to her present illness, when she had the then prevailing epidemic, influenza, and a diarrhœa which threatened to become chronic, and from the effects of which she had hardly recovered, although she had called herself well during the previous summer.

Dr. Richards found her with a general *malaise* and an intense headache, backache, pain in the left side and abdomen. The doctor learned that she had been ill a week, with all the present symptoms. The patient, at this time, had an afternoon temperature of 103° F., and was at the same time so chilly as to require artificial heat applied to the extremities during the height of the temperature. The morning's highest temperature was a degree less than that of the afternoon. She had nausea; the renal secretion was dark and thick, though of normal quantity.

The fever followed about the usual typhoid type, until it had run about two weeks from its commencement. The highest afternoon temperature of this period was 103.5° F. There were no other peculiar symptoms, during this period, than that the height of chill was not fully developed, until the thermometer and patient's face indicated that the highest thermal point had been reached for the day.

August 10. The patient was considered convalescent; temperature and pulse remaining normal two days, then suddenly rising with the on-coming chills.

On the 12th, the temperature rose to 103°F.; the next day it was slightly less, and on the 14th was normal. Again on the 17th it came up suddenly to 104°F., with chills, nausea, and the other symptoms mentioned, and on the 19th it was again normal, and remained so until the 26th. On the 20th a large amount of sloughs passed with the stool twice, and on the 22nd they passed with "greenish yellow matter," as reported on the nurse's record; also on the 24th, 26th and 28th.

On the 26th the fever arose to 103.2°F., and continued rising daily until it reached 105.5°F., and stood nearly as high the succeeding eight days, marking the time for defervescence by dropping to 103° F. for an hour only, morning and evening, the pulse ranging from 90 to 120 in its beats.

On September 4th I was requested to take charge of the case, which I did after consultation with Dr. Richards and Dr. John Bartlett.

I found her with a pulse of 104 and 120, and dicrotic; the temperature was from 103 to 105° F. There was peritonitis, great tenderness and some meteorism of abdomen; tremor, and nausea from catarrh of the head, pharyngitis and laryngitis; there was bronchitis, pain in the renal region, congestion of the pelvis, and ex-

*Clinical Professor of Gynecology, Woman's Medical College.

coriation of the urethra occurred, from which she suffered much.

The renal secretion, though dark, was of normal quantity and above; but this was scarcely noticed until after convalescence, when the record was again referred to. The bladder was washed with warm water and urethra treated. The spleen was so tender that she could scarcely bear the light pressure of bed-clothes, and when turned slightly upon the left side, she was glad to be immediately turned back, to relieve the pain in that side.

September 7th. Meteorism was so great, and gas accumulating so rapidly, that I ordered a syringe rectal tube inserted a short time, twice in the day, by which to remove the gas, as after laparotomy; the intestines were becoming so paralyzed that I looked for perforation, and thought it better to allow increased peristalsis, from the insertion of the tube, than that perforation should occur from such great distension. The mucous from the head and throat provoked vomiting, and milk, though containing one-fourth of its bulk of lime water, was instantly expelled in hard coagula. Constipation continued throughout the fever and was counteracted by enemas.

September 8th. The pulse was distinctly dicrotic; the tremor so great that the patient seemed about to lose form and fall apart, jelly-like. After my visit of the morning I was recalled at noon, as the patient was having "hemorrhage of the bowels," as the messenger reported. I found that a "pint of red blood had passed," as the nurse stated. Turpentine stupes, that the patient had worn under the poultices, were then changed for large compresses, steeped in vinegar and placed over the whole abdomen, and the vinegar of opium was the only medicine given by mouth as the stomach was so irritable, and this in minute quantities.

On the next day there were four stools of clear dark blood and clots only; on the third day there was one large stool of the same dark blood, without clot. About eight days after the hemorrhage began she had a rise in temperature from a sub-normal one to 101° F., followed by an unusually offensive stool, containing much dark greenish blood, after which the temperature fell to normal again. Evidently this was all one hemorrhage, as indicated by the different degrees of decomposed blood, and was estimated to be not less than four pounds.

Subsequent to the first hemorrhage came the most profuse perspiration that I ever witnessed. In twelve hours after it began, the patient had the appearance of having been parboiled, and was dried and changed, as after a bath, several times in twenty-four hours. She also complained that she could hardly see. The failure of eyesight continued for several days. The temperature became sub-normal (the nurse said 94° F.) I took it when it scarcely reached 95°. The pulse was very weak, and but sixty beats per minute. The patient was really cold to the touch, as if all bodily heat had left her.

Numerous bottles of hot water were placed around her, and placed in her hands, thus adding warmth to keep up the circulation. It was difficult to keep up the heart's action, because of the rapidity with which the blood lost its serum, which, with the hemorrhage and perspiration combined must have equalled that in Asiatic cholera.

After the discharge of the last decomposed blood, slow but sure convalescence began. After I had ceased my daily visits, while calling one day, the patient complained that she had no rest day or night, because of frequent micturition, and that the renal secretion was so great. The next day I saw it measured for the twenty-four hours, and it was six quarts; it was dark and heavy with urates, but contained no albumin or sugar. I then referred to the nurse's record again, and saw that, from the commencement of the fever, the quantity had been variable, from twenty-five to forty-two ounces per day; the larger quantities later in the fever, and increasing in amount with convalescence. With a warmer atmosphere, and a dress of flannel, and a liberal use of the tincture ferri chloridi, well diluted, that it might not irritate the diseased mucous membranes, this diuresis was much lessened; after which she became affected with articular rheumatism "in all the joints of the body."

The last disease nearly disappeared in a month or so, and she now, seven months since her fever, is looking more natural and has gained flesh, though the renal secretion is yet more than normal, and she is occasionally slightly lame from the rheumatism.

I am forced to conclude that the rheumatism was the result of checking the elimination of the urates; but I cannot come to a conclusion in regard to the cause of the diuresis with so much uric acid during a typhoid fever.

In reviewing the case, I ask myself, as wiser physicians have done from time immemorial: "What is fever? What its cause and what its result on blood and tissue?" There was increased tissue change here, from bone to brain. There were four periods of fever; *one* of *two weeks*, followed by an interval of two days. The *second* and *third* were of two days each, with an interval between of two days, succeeded by an interval of eight days, and a fourth period of thirteen days, which was nearly one continuous paroxysm, her temperature falling to 103° F., but for about an hour at a time, twice daily.

The second and third short periods were of sudden rise of temperature and slow defervescence. The last, the fourth, beginning on the 26th, six days after the sloughs appeared, I attributed to the sloughing process; but then the question arose as to *why* it did not occur before!

Just previous to the hemorrhage, there was shallow breathing, great tremor, a dicrotic pulse, and such increasing peritonitis that I expected perforation. While thinking how it could be met (for I had never had it occur in my practice, and this was the first time I had anticipated it) I then realized how useless it would be to make a long enough abdominal incision to handle the probable length of intestine affected, to find one diminutive perforation hidden away in near proximity to the mesentery in a most difficult locality to discover.

The manipulation of the diseased bowel, possibly from the cæcum to the pyloric orifice of the stomach, might cause more perforations and the operator leave those thus made, from which the patient would succumb after the closure of the wound; for I have made examinations when there were several patches ulcerated to the peritoneal coverings.

After such a long burning fever, can we expect the blood to be plastic enough to allow new wounds to unite? In this case the hemorrage was succeeded by the defervescence with the very profuse perspiration.

The fever was presumably the effect of drinking unsterilized lake water; and there were two causes for its severity. One, the effect of the previous illness, and the other that her room had no direct rays of sunlight in it, as it was a north room, between two extensions, which subjected it to much shade and in this room she had slept since the May previous.

The influence of sunlight cannot be too highly prized during the treatment and convalescence of typhoid patients. It is reported that Buchner has come to the conclusion, after well-tried experiments, that the effect of the direct rays of sunlight upon bacteria, suspended in water, is to deprive them of vitality; among the variety experimented upon by him was the typhoid bacillus. He suggests that it is this power of the self-purification of running streams that purifies, instead of the action of the water.

If it be proved that Buchner's conclusions are correct, we can expose our patients to the sun's rays and get the same effect, modifying the disease, as there seems to be no remedy by which this so-called "self-limited disease" can in any way be cut short before it, in many instances, destroys the patient's life.

If bacteria are destroyed while in water, why may they not be in the capillaries of the surface of the human body, which though less transparent than a stream of water, is exposed in many square feet of surface in the cuticle, and carries so much blood, the cuticle being the largest organ in the body?

For many years the hygienic treatment of typhoid fever has been to place the patients in well-ventilated rooms, and I would say, in well-sunned rooms. If, during convalescence, a patient is able to be out of his or her room a portion of the day, open it to the sun's direct rays, however hot, during the absence, and always when the patient returns, if practicable.

Do all the present theories of typhoid fever coincide with what we know to be facts? Instance, the pulse is quickned by the influence of the fever, in some way, until the beats are doubled in their number for a given time. Does the theory that the blood is filled with the typhoid bacilli, harmonize with the fact that a foreign body, when introduced into the blood, even while circulating in the blood vessels, affects the formation of fibrin at the locality in which the circulation has been in-

terrupted? Instead of obstructing circulation, do not these bacilli quicken it? If these microscopical bodies have life, and are capable of movement, and are even so small as to pass the lumen of the minutest capillaries, or the walls of the same vessels, one effect should be to thicken this fluid, hence retard the circulation instead of hastening it.

What other influences are at work in this physiological process? The muscular force is weakening, so also the nervous. How are such bacteria eliminated from the system? When we say this fever was the effect of drinking unsterilized lake water, is it saying that the typhoid bacilli are in the water? Some authors assert that sewage alone will not cause this fever. If typhoid bacilli are now in the lake water, are we, in Chicago, to have a perpetual typhoid, or can we turn to Buchner's conclusion, and feel assured that the vitality of those bacteria, now in the water, will eventually be destroyed, and with no new increase, when sewage containing them is turned away?

I have referred but little to treatment, other than exposing the patient to the sunlight, as there is so little to do but direct the care in nursing, which includes feeding, and keeping a patient quiet, both mentally and physically. Yet with every new case I find myself prescribing some one or more of the following remedies: The solution of chlorate of potash, carbolic acid, aromatic sulphuric acid, quinia sulphate, and I have used, in several cases, after the first of the second week, light poultices of simple flaxseed meal over the abdomen, hoping to modify the swelling of Peyer's glands and preserve them from ulcerating.

I have given the chlorate of potash in the beginning of the disease, and carbolic acid later.

## COMMUNICATIONS.

### THE ADULTERATION OF FOOD.*

H. W. WILEY.†

Barnum made a colossal fortune by acting on the principle that Americans like to be humbugged. To be cheated, fooled, bamboozled, cajoled, deceived, pettifogged, demagogued, hypnotized, manicured and chiropodized are privileges dear to us all. Woe be to that paternalism in government which shall attempt to deprive us of these inalienable rights. There is no point on which the average American is more sensitive in respect of legal restriction, than in those instances in which the law interposes to prevent him from making a fool of himself.

In regard to the character of what we eat and drink, we find the same unwillingness to be watched over and protected.

A few days ago in Chicago I went out to the Union Stock Yards to look at the process of meat inspection. From each carcass of pork intended for exportation is taken a sample of the flesh, and this is carefully examined for trichinæ. "Do you often find diseased samples?" I asked. "Yes," said the attendant, "from one to two per cent. of all the samples examined is found infected." "Could I see a sample of that kind?" "Certainly. Has anyone a trichinosed sample in the microscope?" A pretty girl microscopist held up her hand. I looked and saw for myself the curled and coiled serpent ready for a strike. How I congratulated that lucky sarcophagous Teuton who had been saved from a horrid death by the fairy fingers and sure blue eyes of the trichinæ girl. "What do they do with these infected carcasses?" A shrug of the shoulders led me to believe that they were sent to soap factories, as they doubtless are, and this was followed by the expression: "But Americans don't eat raw pork," and I am led to suppose from this that trichinæ are really very good and nice when well broiled. Next morning, when I ordered ham for breakfast, I asked the waiter to have it cut thin and broiled crisp. Even then when

* A lecture delivered before the Franklin Institute, and reported in the journal of that institution. Condensed.

† Chemist of the U. S. Department of Agriculture.

it was brought in I could not help thinking that it looked like a bretzel.

That distinguished jurisconsult and patriot, Senator Paddock, of Nebraska, during the first session of the present Congress, after years of futile struggle, succeeded in having the Senate pass what is known as the Pure Food Bill, but it seems from the provisions of this bill that the Congress of the United States has only power to protect the foreigner, the disfranchised and the Indian not taxed. The provisions of the bill are confined to the Territories and the District of Columbia and to interstate commerce. Mild as are the penalties of the bill, allowing the citizens of any State to make a dessert and call it peas if they like, yet it has been left unpassed in the House of Representatives.

The Paddock Pure Food Bill, to summarize it briefly, has for its purpose the protection of commerce in food products and drugs between the several States, the District of Columbia, the Territories of the United States and foreign countries, and the Secretary of Agriculture is authorized to make the necessary rules for carrying out the objects of the bill. He is authorized to cause to be punished, through the proper courts, any one introducing in any State or Territory, or the District of Columbia, or from any foreign country any article of food or drugs which is adulterated or misbranded. The act says that the term "food" shall include all articles used for food or drink by man, whether simple, mixed or compound. In the case of food or drink, an article shall be deemed to be adulterated if any substance or substances has or have been mixed and packed with it so as to reduce or lower or injuriously affect its quality or strength, so that such product when offered for sale shall be calculated to deceive the purchaser; further, if it contain any inferior substance or substances substituted wholly or in part for the article, or if any valuable constituent of the article have been wholly or in part abstracted, or, if it be an imitation of, and sold under the specific name of, another article, or if it be mixed, colored, powdered or stained in a manner whereby any imperfection therein shall be concealed, or if it contain any added poisonous ingredient or any ingredient which may render such article injurious to the health of the person consuming it. Further, the food is declared to be adulterated if it consist of the whole or any part of a diseased, filthy, decomposed or putrid animal or vegetable substance or any portion of an animal unfit for food, provided that an article of food shall not be considered adulterated if it be a mixture or compound sold under its own distinctive name, or an article labelled, branded or tagged so as to plainly indicate that it is a mixture, compound, combination or blend.

It will be seen by the above provisions that the bill is very far-reaching in its character, and it contains also the proper penalty for enforcing its operation. This bill passed the United States Senate on March 9, 1892.

This Pure Food Bill has received the unanimous support of nearly every agricultural organization in the United States. It has been opposed by a number of manufacturing establishments interested in the production of drugs and mixed foods, and also by those largely interested in the manufacture of substitutes for lard. If adopted it can at once be seen that it would do away with the necessity of the oleomargarine law, which is a special form of legislation, and like all special legislation, must be open to many objections.

As before stated, the national law, as indicated above, does not protect the citizen of any State against an adulterated food which is manufactured and sold within the State. Such police power must be left wholly to the several States. Many of the States already have laws on their statute books dealing with the subject of food adulteration. These laws, however, are for the most part, inoperative, and, not being based on a common plan, would naturally not secure, even when fully enforced, the same degree of protection in all States. What is needed for a complete legal protection of the people against adulterated foods is not only the enactment of the Paddock Pure Food Bill, but a similar enactment of similar scope and aim for each of the several States.

Among the various States which have laws on the subject may be mentioned Illinois, which has an act to prevent and punish the adulteration of articles of food, drink, and medicine, and the sale thereof when adulterated. There is also a special law preventing the adulteration of butter and cheese.

Iowa has a statute, entitled "an act to prevent deception in the manufacture and sale of imitation butter and cheese." One of the provisions of this law is that no keeper of a hotel, boarding-house, restaurant or other public place of entertainment shall knowingly place before any patron, for use as food, any imitation butter or imitation cheese unless the same be accompanied by a placard containing the name in English of such article printed in plain Roman type. Iowa also has a special law in regard to the adulteration of milk.

Maine has a food law to prevent the manufacture and sale of adulterated lard. Maine also has a general law on the adulteration of food and drinks.

Maryland has a statute to provide for the prevention of the adulteration of articles of food and drink and the sale thereof when adulterated or unwholesome. The enforcement of this law is placed largely in the hands of the State Board of Health.

Perhaps the best of the State laws concerning adulteration, are those of Massachusetts, the statutes of which provide "that no person shall within this Commonwealth, manufacture for sale, offer for sale, or sell, any drug or article of food which is adulterated within the meaning of this law." The law of Massachusetts is, in all essential particulars, that of the Paddock Pure Food Bill, of course, with such variations as are necessary in the enactment of a State law as compared with a Federal law. The law of Massachusetts is especially effective as regards the sale of adulterated milk and other adulterated food, and has a system of State inspection which has already reduced the percentage of adulteration of such articles to a very low figure. Monthly returns are made by the inspectors and analysts of foods and drugs. The report for the month of October, which is the latest one, contains the results of the inspection of milk, butter, cheese, olive oil, vinegar, spices, cream of tartar, molasses, maple sugar, maple syrup, honey, tea, coffee, confectionery and miscellaneous articles and drugs. The total number of samples examined was 610; the number found to conform to the legal standard was 428, and the number of samples varying from the legal standard—that is, adulterated within the meaning of the act, 182. The percentage of the adulteration was 29.8. The actual percentage of adulteration is very much less than this, for it is only suspicious articles of food to which the attention of the Board is directed. Certain staple products, such as sugar, flour, and the various cereal products, are very rarely adulterated and receive but little inspection.

The case of Massachusetts is given somewhat at length on account of the excellence of the system of inspection. It shows what a State law can accomplish when wisely made and honestly enforced. In the one item of milk alone, it would be difficult to estimate the amount which has been saved to consumers by the strict enforcement of the law which requires the milk sold to contain a certain amount of total solids and fat.

Time remains only to mention the other States which have laws of some kind on the subject of adulteration. These States are Michigan, Minnesota (which has a series of good laws, both special and general), New Hampshire, New Jersey (which also has a good system of laws), New York, Ohio (also with a fairly good system), and Pennsylvania, which divides its law into three sections; the first relating to liquors, I suppose because this is the most important of the foods of this State; the second to food adulteration in general, and the third especially to dairy products. The weakness of the Pennsylvania law is not so much in the character of the provisions relating to the sale of foods as in the method of securing their enforcement. It does not provide for any system of inspection as does the law of Massachusetts; and no law relating to the adulteration of food is of any value whatever as a protection to the community unless a rigid system of constant inspection is provided for. The Pennsylvania law declares that the addition of water or of ice to milk is an adulteration, and any milk obtained from animals fed on distillery waste is declared to be impure and unwholesome. The removal of the cream is also declared an adulteration. The law prevents the manufacture of any substance provided to take the place of pure butter fat. This is not a restriction on the sale of an adulterated butter, but is a total prohibition of the manufacture and sale of any substitute for butter, even if it be sold under its own proper name.

Continuing the list of States with laws against the adulteration of food, we have

next Virginia and Wisconsin. The latter State has a very good law, which not only has a general provision but also enters into detail, especially in regard to dairy products, describing what shall be considered pure milk, or establishing a standard thereof, and stating how an adulteration of milk shall be proved, and how adulterated honey shall be marked. It contains penalties for the sale of unwholesome provisions and items in regard to the adulteration of foods and drugs, fraud in dairy manufactories, the form of label to be placed on dairy products, the strength of vinegar, etc.

It is hardly patent to this lecture to refer to foreign countries, but it may be said that in general the best laws in this country, national and federal, are based on the English food and drugs act, which is entitled an act to make better provision for the sale of food and drugs in a pure state. This became a law on the 11th of August, 1875.

The laws of the continental countries of Europe are also in the main effective, but contain such a multitude of minutiæ as would render them very burdensome if enacted in this country. The English law has been in operation long enough to prove its efficiency, and under it hundreds of convictions for the sale of impure foods and drugs have been secured.

The Canadian law is essentially the same as that of England, although not so comprehensive.

The States not mentioned in the above list have, so far as could be ascertained, no laws relating to the adulteration of foods. At least they were not reported, although inquiries were sent to the Secretary of State of each State in the Union for information in regard to this matter.

Many municipalities also have local laws applying to the sale of adulterated foods. These laws are mostly of a specific nature and apply chiefly to dairy products. There would be no time here to even mention the cities having local laws on this subject, but there are now very few large cities in the country which do not at least have some kind of milk inspection.

Lying at the root of the question of food adulteration is the inquiry, what is meant by pure food? In the laws which have been enumerated, attempts have been made to legally decide what pure food is. Divested of all legal technicality, pure food is a wholesome article of food or drink which is sold and consumed under its proper name. With each particular article there must be established a separate standard which a consensus of experience with a great number of known pure substances in that list shows to be required. For instance, take the case of milk, which is one of the most common articles of food and perhaps has been more generally adulterated than any other one. Analyses made all over the world on hundreds of thousands of samples of healthy cow's milk, have shown that the average content of solids therein is practically nearly thirteen per cent. A normal milk which falls below this standard shows some peculiarity in the animal giving it, either an incipient disease, deficient nutrition, or some idiosyncrasy. The milk of a herd of healthy animals will rarely fall below this standard. For this reason the standard of twelve and one-half per cent. of total solids in milk has been adopted in most countries having laws on the subject. In some cases the benefit of the doubt is given to the vendor, and a standard is fixed at twelve per cent. Now of these total solids a certain quantity in normal milk must be butter fat. It is not often that the butter fat of a perfectly healthy cow's milk falls below three per cent. of the total weight of the milk. It is much more apt to be three and one-half per cent.; hence, in fixing a standard of pure milk not only must the percentage of solids be given, namely, twelve or twelve and one-half per cent., as the case may be, but also the quantity of fat contained therein. This percentage varies in different laws from two and three-fourths to three and one-half per cent.

In a similar method the standard of purity of any other article of food must be determined by a careful examination of pure samples from all quarters and by then fixing a standard below which an article must be regarded as suspicious or adulterated.

As a distinction between a pure and an adulterated article take the cases of butter and oleomargarine. Pure butter, for instance, must be clean, sweet, wholesome and made of the fat of cow's milk and must contain only a certain proportion of water, curd and salt. Oleomargarine may be as sweet, clean and wholesome as the butter mentioned above, yet

when sold as butter it is clearly not pure food, but a spurious article.

Again, when the housewife buys lard it is supposed that the article she obtains has been made from the fat of healthy, freshly slaughtered hogs, carefully selected and cleaned and rendered in clean kettles or tanks. Cotton-seed oil and beef tallow, in respect of cleanliness, nutritive properties and the wholesomeness may equal and even excel pure lard, but the admixture of these article with hog's lard, or their sale as such without the knowledge of consumers, is clearly a fraud and an adulteration.

From a practical point of view, food adulteration may be considered under two general aspects, namely:

(1) Adulteration harmless to health and practised merely for cheapening the article or making it more attractive to the sight or taste.

(2) The addition to a food or drink of substances positively injurious to health.

Such substances are added chiefly as preservatives or for the purposes of coloring or declorizing, or for the purpose of giving a particular flavor or taste. As a rule, they are added in minute quantities. In fact, the proportion of such substances is usually so small that a moderate or intermittent use of food so treated may not produce any great injury to the system. The continued use of such articles, however, must end in the impairment of the general health and sometimes in permanent injury.

In the latter class of adulterations must also be included those injurious substances naturally arising from the decay of wholesome food, or from the development of noxious substances in canned foods, or from the formation of poisonous salts by the action of the canned foods on the solder and tin of cans. Such materials, while not intentionally added, are, nevertheless, adulterations within the true scope and meaning of the term as applied to foods. In other words, it is not necessary to prove intent in order to establish the fact of adulteration. Any food which is not what it purports to be, which contains any unwholesome or poisonous ingredient, or which has any artificial coloring or facing material, is, to all intents and purposes, adulterated.

There is one legal exception to the above classification, namely, the use of annatto in coloring butter. The national oleomargarine law, applied to the Territories, the District of Columbia and to interstate commerce, permits an artificially colored butter to be passed as genuine, and I believe most State laws referring to this subject contain the same provision. Indeed, in some States oleomargarine exposed for sale is required by law to be stained pink or some other color distinctive from yellow, and such a stain, while an actual adulteration, could not be classed as illegal.

There is still another form of fraud in food which may be defined as a negative adulteration. It consists in extracting from a food part of some valuable ingredient, and selling the residue as the genuine article. The sale of skimmed milk for whole milk, and of spent tea leaves for genuine leaves, are illustrations of this kind of fraud. Perhaps the best method of illustrating these various kinds of fraud and adulteration will be to call attention to some of the articles sophisticated in the ways described. No attempt, however, will be made to give a complete list of adulterated articles, for such a list would fill a volume. Attention, therefore, will be called only to the more important articles of food, and to those which are most commonly adulterated. In addition to this, examples will be given of some peculiar forms of adulteration which are little known to the public.

*Milk.*—Normal cow's milk should contain about three and one-half per cent. of butter fat, and should yield, on standing in a cool place for twenty-four hours, from ten to twenty per cent. by volume of cream. Until the establishment of milk inspection in cities, whole milk was something of a rarity. With careful inspection, such as obtains in Boston, the percentage of adulteration has been largely reduced.

An ingenious method of milk adulteration is sometimes practiced by the shrewd husbandman in such a way as to preserve his tender conscience from being seared. The cream in the cow's udder is naturally separated in part from the milk, unless the cow, just previous to milking, be subjected to violent exercise. The first milking, therefore, is less rich in butter fat, and it can be sent directly to the consumer. The last of the milking, called strippings, on the other hand, is nearly pure cream, and can be preserved

for butter-making. Butter fat, being lighter than whole milk, cannot be removed without increasing the density of the remainder above the normal. This density, however, can be reduced to the proper limit by the judicious addition of water. The testing of milk by the lactometer alone is therefore not a certain method of discriminating between a pure and an adulterated article.

Condensed milk is made by evaporating whole milk at a low temperature and in a high vacuum, in copper vessels, yet even at this low temperature some of the distinctive aroma of the milk is carried off by the escaping vapors. It therefore happens that even when evaporated milk is diluted to its original volume with water, it is never exactly itself again. Yet a pure condensed milk is not an adulterated article, for it is sold as condensed milk, and hence no fraud is practiced. When, on the contrary, as is often the case, sugar or salicylic acid is added in order more securely to preserve the condensed product, then a perfect case of adulteration is established. The manufacturer, however, may relieve himself of all responsibility, in so far as the addition of sugar is concerned, by stating on the label the amount added. In cases of deleterious preservatives, however, there would be no excuse. Their use in all cases should be prohibited.

*Butter.*—In regard to butter, the character of adulteration is well known. The use of oleomargarine as a butter substitute has been practiced for many years. The oleomargarine law, which imposes a tax of two cents a pound on the manufactured product, has not helped to restrict its use, but has rather increased it by giving to the consumer a guarantee of purity.

There can be no reasonable objection to the use of oleomargarine; it is clean, wholesome and digestible. When it is to be kept for a long time before use, as on ship board or in distant mining camps, it is preferable to butter, because it has but little tendency to become rancid.

*Lard.*—For similar reasons there can be no possible objection to the use of cotton-seed oil as a substitute for lard, or when mixed with lard, provided it be sold for what it is. Most of you are familiar with the great fight which was made against the use of the term "pure refined lard," which was the trade name of a mixture of lard stearine with cotton-seed oil. "Pure refined lard," it was claimed, was a term which had been used so long to designate the mixed product that it had become in reality a trade-mark, and was therefore entitled to respect and protection. In the investigation which was held before the Congressional committees, it appeared that as to the trade the contention was quite justifiable. Goods sold under that name were understood to be mixed. When, however, the mixed product was offered to the consumer, it was purchased with the idea which the name naturally implied, that an extra fine quality of hog's lard was secured.

All attempts to pass a pure lard bill, modelled on the Oleomargarine Act, have heretofore failed in Congress, but several of the States have prohibited the sale of mixed lard, except when offered under the proper name. Manufacturers have, therefore, been gradually forced to abandon the term "refined lard" when applied to this commodity.

I am of the opinion that many persons would prefer a cooking fat largely of vegetable origin to a pure animal product. To me it seems that some State Legislatures have taken a reprehensible course in prohibiting the sale of vegetable oils as a substitute for lard for cooking. The grower of hogs undoubtedly has a right to contend against the sale of vegetable oils as hog fat, but when he pushes his claim still further and demands that the markets be closed to products as pure and nutritious as his own, he passes beyond the bounds of public support. Every person in the United States who prefers cotton oil to lard should be allowed to purchase his supplies without let or hindrance. Every grower and maker of pure lard has the right to an equally open market, from which every adulterated and mixed lard, offered as pure, should be rigidly excluded.

For a time, a few years ago, when a popular fad prevailed in favor of nitrogenous foods, the true value of fats to the digestive and nutritive economy was not well appreciated. At the present day this is all changed, and we know how to value a fat properly.

It is therefore a matter of no mean importance to protect the public in the use of olive oil instead of cotton oil, of cotton oil instead of lard, and lard instead of a mixture of beef and cotton oil stearine. It is true that cotton oil, when carefully re-

fined, is almost as good a salad dressing as olive oil, but it is very much cheaper, and those who prefer to pay the high price should be secured against fraud. In respect of wholesomeness and digestibility it would be hard to choose wisely between the two.

One of the great difficulties in securing the enactment of a National Pure Food Bill has been the feeling in cotton-growing regions that such a bill would restrict the market for cotton oil. This is true if the fraudulent market is meant. By that I mean the surreptitious sale of cotton oil as olive oil and as lard. But such a bill would not interfere in the least with the legitimate market for this product. Cotton oil, as a food, has such merit of its own as to warrant the belief that it does not require any smuggling to secure for it a wide and rapidly increasing use. The South as well as the North would be the gainer from honest markets for honest foods, and it is such a short-sighted policy that leads to a crusade against such legislation as will secure the desired result. It would be a rather unfortunate thing for the whole country should an irrepressible conflict between the *sus* and the *gossipyum* keep our interstate market forever open to mixed or doubtful fats.

*Sugar.*—The common idea that the grocer puts sand in his sugar is not borne out by the facts in this country. I doubt whether a single pound of white sand has been put into the sugar supply of this country in the last ten years. It is one of those popular fallacies which gain credence inversely proportional to their truth. The granulated and white lump sugars which are found in our markets are almost absolutely pure; as pure indeed as the utmost care in manufacture can make them. Occasionally a little flour or starch may find its way into the powdered sugar, but such instances must be exceedingly rare. Low-grade sugars contain molasses and water as a result of the way in which they are made and dried. In the refiners, after the pure white sugar has been secured, the molasses therefrom is reboiled and a second crop of sugar crystals obtained. These form the so-called coffee sugars of commerce. In a like manner a third crop of rather light colored crystals may often be formed. By a combination of low temperature and high vacuum in boiling, and by a manipulation producing small crystals, a sugar can be made very soft, and, so prepared, it absorbs a good deal of the mother liquor in which its crystals grow. It is possible, in this way, to put on the market a fairly light-colored and attractive sugar, which may not contain more than eighty-five per cent. of pure sugar. This process of making low-grade sugars is practiced chiefly with the product of the sugar cane. In sugar from beets the molasses and mother liquors are usually so highly charged with alkaline salts as to render the manufacture of low-grade sugars, fit for table use, a very difficult matter. In this country, as is well known, the greater part of the sugar consumed is made from sugar cane. Of the 4,000,000,000 pounds which we have eaten in the last twelve months, probably 3,500,000,000 have been grown under tropical suns. The proportion of yellow, coffee, and low-grade sugars offered is therefore, greater in our markets than in Europe, where the sugar beet supplies nearly all of the sugar consumed.

*Syrups.*—In respect of molasses and syrups the bill of health is not quite so clean. The quantity of pure maple syrup sold annually is well calculated to make the maple forests of Vermont prick up their ears. A very little maple molasses mapleizes the whole jugful; a fact that makers and sellers have not been slow to learn. An extract of hickory bark imparts a misleading flavor to a syrup made from cane sugar and starch, and a patent has been granted by the United States protecting the discoverer of this process in the exercise of his invention. Judicious mixturer of glucose, sugar, syrup, and maple-flavor are the secrets of the marvelous expansiveness of maple molasses between the tree and the gullet.

"Golden drips," "honey syrups," etc., are names given to compounds made of refinery refuse, glucose and centrifugal cane molasses. The great base of all our table syrups is glucose made from corn starch. I am far from denouncing glucose as a dangerous ingredient in such mixtures. On the contrary, when glucose is properly made, it is both palatable and wholesome, but its sale as maple molasses or as refiner's syrup or as open kettle molasses is clearly fraudulent.

*Honey.*—Liquid honey is very largely adulterated with glucose. Of 500 samples of honey bought in fifteen large cities and

examined by the chemical division of the United States Department of Agriculture, nearly forty-five per cent. were found to be fraudulent. Of comb honey, only that is adulterated which comes in bottles or jars. A few years ago there was a popular impression, which I shared, to the effect that comb honey in the frame was adulterated; but no sample of this kind has ever come under my observation, and I am convinced that such a species of adulteration does not exist. Perhaps there is no class of food producers in the country whose business has been so seriously injured by adulteration as the bee growers. Many of them, however, do not seem to realize the magnitude of the frauds which are perpetrated against them. They have often been known to denounce, as attempts to injure their business, the statements that such frauds are practiced. Of late, since indubitable evidence of fraud has been presented to them, they have determined to use every means to end it.

*Coffee.*—Almost equally subject to adulteration is ground coffee. The high price of coffee is a special incentive to sophistication. In former days it was largely the custom to buy the green berry, and each consumer would do his own roasting. Now it is fashionable not only to buy the roasted berry, but also to buy it in a ground state. Chicory, roasted peas, beans, etc., are often found in large proportions in such preparations, and in fact it is somewhat rare to find a pure ground coffee. It might be held that such sophistication would end with the ground article, but such is not the case. The berries themselves have been imitated both in the green and in the roasted state. The moistened mass of chicory, starch, pea meal, caramel, molasses, etc., is moulded into the proper shape, and, when dried, these imitations might easily escape detection when mixed with the genuine berries. Those who are so fortunately situated as to be permitted to live at home and regale themselves each morning with an aromatic cup of Mocha or Java, scarcely realize what it means to drink a lukewarm concoction of chicory and pea meal, bluish black in color, but decidedly yellow in flavor.

*Tea.*—Thanks to our custom laws very little tea is found in this country adulterated with foreign leaves. The chief adulterations practiced with tea are found in the use of spent leaves, and in the practice of facing. The practice of facing consists in treating the leaves with some preparation designed either to increase their weight or to improve their appearance. Salts of iron or copper are often used for this purpose. Some of these facing materials are quite prejudicial to health, and such teas are best excluded from the breakfast table.

*Cocoa.*—Cocoa and chocolate are largely adulterated with starch and sugar, harmless in themselves, but far cheaper than the meat of the *cocoa theobroma.* The natural oil of the cocoa bean is also often extracted, and its place supplied by a cheaper fat or left without an oil. These various preparations are offered under fancy names and with wonderful claims of excellence. But in general we may say that the food value of a preparation is not much improved by having it digested before it is eaten. Yet often we see it claimed for a given mixture that it has had all of its difficultly digested components removed and that these are replaced by others with which the gastric juice can have a veritable picnic. The digestible cocoas often belong to this class, and, perchacne, may have little of the virtues of the original beans left in them.

*Canned Foods.*—Of canned foods I should like to say something, but it is difficult to select the little which can yet be said. First of all, the material of which the cans are composed is a matter to deserve attention. It is undoubtedly true that glass is the ideal substance for cans designed to preserve food products. But the first cost of these packages and the danger of breakage during filling and transportation, exclude them from competition with tin in all except the choicest brands of preserved foods. Fortunately, tin is a metal which is not only troublesome to the tariff but also resistant to most organic acids. It is acted on very slowly or not at all by most organic acids found in fruits, vegetables and meats. In some countries, such as Germany, the tin which is used in contact with canned foods is required to be almost pure, and to contain not more than one or two per cent. of lead. The most abundant adulteration of tin, as found in tin cans, is lead, and it is against the presence of lead that it is especially necessary to guard, inasmuch as the organic salts of lead, without exception, are poisonous. In

this country of personal liberty there is no restriction as to the percentage of lead which tins used for canned fruit may contain. We have found as high as twelve per cent. of lead in tin from cans which have contained food designed for consumption. Such a high percentage of this dangerous metal cannot fail to excite alarm. We have also found numerous evidences of erosion on the tinned surfaces exposed to the action of the contents of the can. The tact of the preserved goods with solder should also be carefully prevented, inasmuch as solder contains often as much as fifty per cent. of lead. It is very common, however, to find lumps of solder in the canned-goods and also to find the solder protruding through the points of union of the can and cover so as to be exposed to the action of the contents.

*Copper in Peas.* Equally objectionable is the habit of using copper salts to impart a bright green color to canned peas and other goods. The imported French peas are uniformly colored with copper. The addition of a little copper, in any vegetable which it is desired to keep green when served, has a happy effect in that direction, and fashionable cooks have not been slow to learn this. It is true that the quantity of copper which one would eat in a single meal where French peas are served, would not prove greatly injurious, but on that large part of our population who are compelled to dine every day on truffles and peas interspersed with terrapin and champagne, there is great danger of the copper acting with accumalative effect.

I have already spoken of the danger which may lurk in preservatives, such as salicylic acid, but there is also an occassional source of danger in the development of nitrogenous bodies called ptomaines in preserved meats. These bodies may develop with astounding rapidity if a can of meat be opened, and not eaten for a day or two. An illustration of the fatility of the action of such bodies is unfortunately often found in the case of tyroxicon, a poison often developed in milk or cream.

The above will serve as illustrations of the more common forms of adulteration to which our foods are subjected. The idea might be formed from this array of facts that foods are almost all adulterated, and that it is extremely difficult to obtain anything pure. Newspapers love to magnify these accounts of adulteration. What I have placed before you has not been for the purpose of exciting a panic on the subject of foods. Much the greater part of foods which Americans eat is pure and wholesome. It is only the small quantity of adulterated food from which we should strive to protect ourselves.

The popular idea of adulteration is really very much at fault, and this has been due largely to the exaggerated statements of presumably honest men, who desire to call attention to the fraud and to prevent it by exciting the popular mind against it. The adulteration of our foods and drugs is certainly bad enough, but in my mind it does no good whatever to exaggerate, falsify and misstate the results of careful and unbiased investigations. As has before been intimated, in this address, the remedy against all these things lies clearly in the power of the people. Wise laws wisely administered, a careful system of inspection, a demand for pure food, will secure the people in their right. It is not the rich for whom we should work, but the poor, and they should be protected against frauds in food ; frauds not so dangerous on account of being deleterious to health as because of their pretensions to furnish to the poorer part of our people a food ostensibly pure and nutritious but in reality valueless. It is not supposed for a moment that any system of legislation can entirely prevent the perpetration of frauds upon the community, but at least these crimes can be made punishable and their perpetrators may be compelled to endure the penalty of their misdeeds.

---

Dr von Blarcom, one of the most distinguished physicians in Berlin, expresses the opinion after careful investigation that coffee long boiled produces more indigestion than any other substances taken into the human stomach, and that a simple infusion facilitates digestion.—*Public Opinion.*

---

It appears as if the people of the United States were steadily reducing their consumption of quinine and other cinchona alkaloids. Year after year since 1887 the importance of cinchona bark have been diminished. In 1893 the amount imported was less than half that of 1887.—*Popular Science News.*

## INFLUENCE OF GONORRHŒA IN THE PUERPERIUM AND DISEASES OF THE EYE IN THE NEW-BORN.*

Dr. Richard v. Steinbüchel has collected for his studies 313 cases, with as many new-born infants. The diagnosis of gonorrhœa in the mothers was based principally upon the clinical symptoms, which the author regarded as more readily depended upon than the study of the gonococci. He states that while the gonococci are present, as a rule, in gonorrhœa, they may be absent in typical cases for a few days, after which they are often seen again in greater quantities, thereby making a diagnosis based upon microscopical or bacteriological investigations more difficult than by the clinical method.

His diagnoses are based principally upon the methods of Sanger:—

1. The existence of slight catarrh of the urinary passages containing pus cells.
2. The demonstration of pus in the urinary passages, as also the deeply reddened and swollen margins of the urethral mucous membrane.
3. Inflammation of the Bartholinian glands, having the appearance of a dark purple ring around the opening of the glands (macula gonorrhoica.)
4. Condylomatous points at the vulva, vagina or cervix.
5. A purulent or muco-purulent discharge from the cervix connected with an erosion of the os.

Having made the diagnosis of gonorrhœa in the mother, principally based upon clinical facts, the rule was to prevent, if possible, the entrance of the gonococci, usually present in the vaginal discharges, from entering into the eyes of the new-born. Of 313 new born there were 13 suffering from some affection of the eyes; of these, 9 were not virulent; 4 were of the blenorrhaic type. Of the 4 children suffering from blenorrhœa, 1 was found to belong to a mother who was not suffering from gonorrhœa, hence the child must have been infected after birth. The low percentage (4 cases of ophthalmia, 1.28 per cent. from 70 mothers suffering from gonorrhœa equalling 21 per cent.) may be due to the use of Crede's method, which is often left in inexperienced hands.

The influence of gonorrhœa upon the puerperium could be studied by the author only during the interim of 8 days after the confinement, since the patients were usually transferred after that to another department; S. concludes from observations made during this time that this disease did not have any marked influence on puerperal diseases in general. Seven of the gonorrhœal patients had a rise of temperature in the first 8 days (10 per cent.) while the rise of temperature in those not suffering from gonorrhœa was 9 per cent. as a rule. The first group contained one fatal case, and the second two, caused by sepsis (due to an epidemic of erysipelas, the hospital contained no room for isolation.)

After some energetic investigations into the subsequent histories of some of these above mentioned cases, S. traced eight. Six of these were grave affections of the tubes, ovaries, and peritoneum. The first symptoms set in between 3 to 12 weeks. The author states that the lochial discharge carrying with it, as it often does, shreds of mucous membrane, may be the cause of the delay of active symptoms, which he proves by the facts that as soon as the discharge ceases and the involution progresses the symptoms of the gonorrhœal infection become more marked. —*Deutsche Med. Zeitung*, March, 1894.

THE Zoothermic Institute in Rome is a "cure" place, where people go to drink fresh blood for the cure of gout, rheumatism and the great prostration and anæmia caused by the malarial fevers of the Tontine Marshes. The blood to be imbibed is first rapidly freed from fibrin by a carefully aseptic method, the animals from which it is derived having previously undergone inspection by a veterinary surgeon. Some patients bathe either a part or the whole of the body in the warm blood, and the Italian doctors think, with great benefit.—*New York Independent.*

## THE FINAL RESULTS FOLLOWING THE EXTIRPATION OF THE ASTRAGALUS FOR THE TREATMENT OF THE VARIOUS FORMS OF CLUB-FOOT.

In a monograph on this subject, J. G. Gohl considers at length the etiology of this affliction in its various forms. In the case of a congenital club-foot of aggravated form, the wound healed, without any complication, within five days. The patients were permitted to make some efforts in walking and succeeded so well that at the end of fifty days they were discharged cured, any external support being deemed unnecessary after that time.

(One of the two cases—pes varus congenitus duplex—in which extirpation of the astragalus, a portion of the calcaneous and cuboid, necrosis of the toes and the metatarsus set in.)

In those cases in which paralysis existed, due to disturbed functions of the muscles, it was always deemed necessary to improve the patient's general health in order to insure a rapid and healthy union of the surfaces operated upon. The usual time between operation and discharge was between fifty to sixty days. The immediate results of the two cases belonging to the cicatricial variety were perfect, but it was impossible to make any statement regarding their permanent cure since both died by some intercurrent disease.

The desirable feature in this operation is that there is no need for the usual after treatment with external supports. It is necessary to begin early with passive, and later active motion followed by massage—a firm support for the ankle is needed only immediately after the operation in order to sustain the still somewhat weakened joint. The greatest care should be exercised in sustaining the ankle by properly selected shoes.

The excision of the bones produce but a slight degree of shortening and may be readily overcome by thicker soled shoes. There are a number of plates showing casts of feet, before and after the operations.—*Centralb f. Chirurg.*, No. 8, 1894, It may be interesting to add in connection with this that Dr. Thos. G. Morton, of Philadelphia, has operated on about thirty cases in much the same manner, taking great care to remove all the bony obstructions to insure a thorough correction of the deformity, having preceded this by a tenotomy of all the flexors and extensors which seemed to require it. All the cases made an uninterrupted recovery, and were thoroughly and permanently cured.—M. B. W.

## THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

### PICRIC ACID IN SUPERFICIAL BURNS.

Dr. P. Filleul, (*La Semaine Médicale*, No. 7, 1894) states that at the Hôspital de la Charité in Paris, picric acid has been employed with success for several years in the treatment of superficial burns. A saturated solution is applied on gauze compresses; they must be carefully wrung dry before they are laid on, and if the dressing remain antiseptic, it does not require to be changed frequently; at first every three days and then every four, five or six days. No impermeable protective is necessary for they are simply allowed to dry on the burn. Besides being antiseptic and healing it also calms the pain. There is no danger of poisoning, of irritation of the skin, nor of any other disagreeable side-action. The only disadvantage is the yellowish discoloration of the parts with which it comes in contact.

*In charge of the translator, F. H. Pritchard, M. A., M. D.

### SUBLIMED SULPHUR IN DIPHTHERIA.

Dr. Baeumler (*Muenchener Med. Wochenschrift*, No. 10, 1894) recommends sublimed sulphur in the treatment of diphtheria from the results obtained in an experience of over seven years. The powder is applied to the affected parts, at first, every one to two hours and eventually every three to four times a day, by means of a large and soft camel's hair brush; during the intervals, a weak solution of permanganate of potash is used as a gargle. The results of this treatment

were better than those obtained with previous methods. Even severe cases, with extensive gangrene of the soft palate, often pursued a favorable course. He advises an extensive employment of sulphur in this disease.

### IODINE IN ACTINOMYCOSIS.

Dr. Ostertag (*Deutsche Med. Wochenschrift*, No. 9, 1894) thinks that the treatment of actinomycosis by the iodides as recommended by Thomassen, has not met with the recognition that it deserves. He concludes from his experience as well as from that of others, that iodine is an actual specific in this disease. In the treatment of cutaneous and subcutaneous actinomycotic growths, a deep crucial incision was made and the hardened tissues painted, once a day, with the tincture of iodine. Internally iodide of potash was given in aqueous solution, once or twice a day. In two to four weeks recovery would follow. Bass, Fuertmayer, de Jong and others have also obtained similar results. The result was analogous to that seen in gummatous tumors after administration of the iodide.

### ETHER LOCALLY IN INCARCERATED INGUINAL AND FEMORAL HERNIÆ.

Dr. Lyncker (*Wiener Med. Presse*, No. 12, 1894) has used ether locally, for the last five years in the treatment of severe cases of incarceration in inguinal and femoral herniæ and has not been obliged to resort to surgical measures even in the severest cases. If reduction was found impossible, an injection of morphine was given and every quarter to half hour, a teaspoonful of ether slowly poured onto the hernial tumor. In thirty cases treated thus painless reduction was possible even after incarceration had existed for several days and the hernia was large. He can only recommend this method most heartily. (An injection of atropine and morphine into the region of the ring with elevation of the pelvis is also an excellent proceedure; Gussenbauer advises also the local application of ether, but with elevation of the pelvis, which latter measure is of itself of value.)

### GUAIACOL IN DIABETES AND THE POLYURIA OF DIABETES.

Dr. T. Clemens (*Wiener Med. Presse*, No. 5, 1894) praises the action of guaiacol in the treatment of diabetes and the associated polyuria. The dose of the (pure) drug was three to six to ten drops, three a times day, in a tablespoonful of milk, or, if tolerated, in an eggcupful of cod-liver oil. In order to control its influence he did not order any special diet and examined the urine, passed after dinner, on several consecutive days. After the patient had taken the drug for eight days his urine which usually contained from 1.86–2.90 per cent. of sugar, in the afternoon, showed a very considerable reduction; in some cases the sugar was only present in a very slight quantity, in a few entirely lacking. After it had been taken for two to four weeks, here and there, a few sweet foods containing sugar could be allowed without influencing the amount of sugar in the urine. A still more striking action was observed in the polyuria of diabetics. In some cases, in eight days the quantity of urine was reduced by half. This was controlled by discontinuing and reducing the dose of the drug. In all cases the general condition was improved while the remedy was well borne.

### PIN WORMS.

Dr. Etter (*Norsk Magazin for Laegevidenskaben*, No. 1, 1894) claims that the best remedy for pin worms is to catch them. In the evening at about bedtime when these worms take their evening promenade the patient should be placed in the knee-elbow position, the anal folds separated and the active little creatures be caught with a small pair of forceps. The first day will yield the best results but one should not discontinue the search too early even though no worms have been seen for several evenings.

### SYPHILITIC INTERCOSTAL NEURALGIA.

Dr. Obolenski (*Medicinische Neuigkeiten*, No. 9, 1894) reports several cases of intercostal neuralgia of a syphilitic origin. Diagnosis was made by exclusion and confirmed by the immediate and rapid results obtained with mercury. As characteristics, he calls attention to the bilateral appearance of the pains, their setting in or becoming more pronounced during the night and their aggravation at night—osteocopic pains.

**TERMS:**—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

**REMITTANCES** should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

**NOTICE TO CONTRIBUTORS:**—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 21, 1894.

## EDITORIAL.

### A NATIONAL DEPARTMENT OF PUBLIC HEALTH.

Elsewhere in this number will be found in full the text of a bill prepared by a special committee of The American Medical Association, together with the memorial framed to introduce the bill to the National Senate and House.

The memorial intimates some excellent reasons for the enactment of the bill, but we are inclined to think that the petition, although exhausting, is couched in terms too general to avail much with the average law-maker. The improvements desired involve some radical measures. It asks for the establishment of a Federal Department of Health with an executive head who shall be a member of the Presedent's Cabinet, the peer of all other members of that body. In our opinion the bill is reasonable, wise, beneficent and timely. It seeks the formation of the department on a very broad basis but leaves the details of organization and development to be worked out by the department itself within limits abundantly wide and at the same time distinctive. A reading of the proposed measure will commend it to everyone as a righteous and necessary act of public policy and one calculated to greatly enhance the well being of the citizen himself. Senator Sherman is expected to introduce the subject in the upper house, while Mr. McCreary of Kentucky, will present it to the House of Representatives.

Meantime another and much inferior bill, engineered by the New York Academy of Medicine, has already been introduced to the House and by it referred to the Committee on Interstate Commerce, before whom advocates of the measure were given a hearing at Washington, D. C., on March 28th. According to the New York *Medical Record*, "short addresses in favor of the bill were made by Drs. T. Gaillard Thomas, Richard H. Derby, J. H. Girdner, George F. Shrady and T. Mitchell Prudden, of New York, Professor William H. Welch, and President Gilman, of Johns Hopkins University, and by Dr. Rohé, of Baltimore, representing the National Bu-

reau of Health Committee of the Medico-Chirurgical Faculty of Maryland. The speakers were most attentively heard by the Congressional Committee, and much interest was manifested in the purposes of the bill."

Marked inferiority of this latter bill will be made evident by comparing the measure proposed by American Medical Association with the following:

---

ANALYSIS OF PUBLIC HEALTH BILL PROPOSED BY NEW YORK ACADEMY OF MEDICINE—BUREAU OF PUBLIC HEALTH.

The Bureau. Two Commissioners-at-Large; nine District Commissioners; four Ex Officio Commissioners.

Officers elected by Bureau. President and Vice-President, to be elected from Commissioners-at-Large (outside Secretary).

Compensation. President, ($15 per day; all other Commissioners, ($10 per day; Secretary, $3,000 per year.

Executive Committee. The President and the four ex-officio Commissioners.

Duties of the Bureau. Make rules for duties of Executive Committee; make rules for guidance of Bureau and employes, establish rules for government of National sanitation, foreign and Inter-State special departments; may call conference with State Boards.

SECTIONS 5, 6, and 7. Collect and diffuse information; advise the Departments of Government, Executives of the several States, all Health Authorities when called for, or when the Bureau thinks best, to to secure sanitary condition of vessels from foreign ports; to prevent the introduction of contagious and infectious diseases and their spread, and to be the Government medium for National sanitary action; may make investigations abroad, and the President of the United States may, on request, detail officers from the several Departments of the Government.

SEC. 8. Shall report facts to Secretary of Treasury.

SEC. 9 and 10. Shall obtain information of sanitary condition of foreign countries from Consuls and from domestic sanitary authorities, and transmit same to various public and State officers.

SEC. 11 (dup. of Sec. 6). Shall furnish information and advice to States and Government Departments when requested.

SEC. 12. Shall co-operate with State authorities and secure uniform system of notification.

SEC. 13. Shall make rules for vessels engaged in foreign trade.

SEC. 14. Shall issue rules and regulations to Consuls.

SEC. 18 and 19. Shall have authority to forbid entry of vessels under certain specified conditions, and may order vessels to quarantine; may send to National or State quarantine in case of epidemic.

SEC. 20. May exercise Inter-State quarantine authority.

SEC. 21 and 22. Provides for purchase of State quarantines.

SEC. 25. Shall make an annual report, and its correspondents may have franking privilege one million appropriations. District Commissioners, Sec. 8. Examine into health measures employed in respective districts, and report same to Bureau, and thereafter make annual reports of sanitary affairs of his district.

Surgeon General of the Army, execute all orders, rules and regulations relating to sanitation in his branch of the Public Service.

Surgeon General of the Navy. Same as above.

Surgeon General Marine Hospital Service. Perform all duties in respect to quarantine and quarantine regulations provided by this Act."

This analysis was made of the original proposition of the New York Academy of Medicine, which, however, latterly withdrew the original bill providing for sanitary districts, and substituted a very much better one, but retaining the great defect of organizing as a "Bureau" in an already existing Department. It would seem that the latter measure could be advocated only on the grounds of expediency—that half a loaf of bread is better than none at all.

The REPORTER does not anticipate any action on either of these measures by the present congress. Because the measure is non-partisan, non-sectional, is not rendered absolutely compulsory by the imme-

diate pressure of public opinion, and principally because it is pure common-sense. A glance at the Capitol shows the House striving to solve the arithmetical problem of counting a quorum and each time obtaining a result which fails to prove by the test of "a call of the House," while the Senate is agonizing in the throes of the second stage of a parturition, complicated by a cross-presentation and showing every sign of impending eclampsia. It would be folly to expect our legislators to pause in the manipulation of these most important projects long enough to consider a measure whose prime recommendations are its utility and wisdom.

But the energy thus expended is not wasted, for we can bring greater pressure to bear each time we repeat the effort, until we eventually succeed as we will. In the meantime public opinion will grow stronger and stronger as it appreciates the value of the object lessons presented by the various State Boards of Health, many of which are doing most efficient service within the limit of their powers, thus giving incontrovertible evidence of what can be accomplished by such a body invested with national powers and authority.

A very great impetus can be given this most desirable movement if medical societies will officially express their approval and urge upon Congress the establishment and equipment of a Department of Public Health on a parity with the other governmental departments.

# ABSTRACTS.

## A PETITION TO ESTABLISH A DEPARTMENT AND A SECRETARY OF PUBLIC HEALTH.

*To the Honorable the President of the Senate and the Speaker of the House of Representatives of the Congress of the United States of America.*

The American Medical Association at its meeting at Washington in May, 1891, adopted unanimously this resolution:

"*Resolved*, That the President of the Association. W. T. Briggs of Tennessee, appoint a committee to memorialize the next Congress to create a Department and a Secretary of Public Health."

At the meeting of the Fifty-second Congress in December, 1891, a petition and a bill to that effect were introduced in both Houses; in the Senate by the Hon. John Sherman, and in the House by the Hon. John A. Caldwell, and they were referred to certain committees. No report has ever been made to either House on the subject.

At the annual meeting of said Association in the City of Detroit in June, 1892, the Committee reported the failure to secure any action of Congress on the petition; whereupon the Association again directed the select committee to renew its appeal for Congressional action; but no notice was taken of it, chiefly because the alarm at the approach of cholera from Europe led Congress at once to enlarge the existing quarantine system which it was supposed would answer all purposes.

The Chairman of the Committee addressed a communication to the Chairman of the Committee on Contagious Diseases in the Senate, which set forth that while the quarantine measures were very effective so far as the hindrance to transplanting the disease of other lands were concerned; yet they did not include all the measures for the operation of preventive medicine which the American Medical Association was seeking to establish for the public welfare.

The only answer made at any time by this gentleman was merely verbal, and that it was his belief that Congress would not appropriate money that would increase public expenditure.

At the annual session in Milwaukee in June, 1893, these facts were reported, and the Special Committee was ordered to renew the appeal at the approaching Fifty-third Congress. Under this authority

the undersigned beg your consideration of the whole subject anew.

In the Pan-American Medical Congress, which met in Washington in September, 1893, under the auspices of our Government, the most august assembly of medical men that ever met in this hemisphere, this question was carefully discussed and unanimously approved. Moreover, a large number of State Boards of Health, the National Board of Public Health and numerous medical societies in different cities and States have given their adhesion to this movement.

The American Medical Association is constituted of men of distinction in every part of the Union. For more than forty years its sessions have been held in the chief cities of the States lying between the Atlantic and Pacific coasts, and it represents nearly one hundred thousand intelligent and well-known citizens. The annual sessions have greatly promoted scientific research into the causes and treatment of diseases of every character, the formation of State Boards of Health, higher medical education and the publication of treatises on preventive medicine and medical practice which forms a continuous line of medical progress in the last half of this century.

The Government, through the operations of the Surgeons-General of the Army, Navy and Marine Hospital service has made liberal expenditures for the National Medical Library and its Index Catalogue, a Pathological Museum and some investigations on the origin, nature and spread of the fearful infectious germs that are brought to us by immigrant and other ships. But the medical profession believes that the Government can, in a wider way, promote the public welfare by creating a Department of Public Health, the head of which should be a physician, a member of the Cabinet and on a parity with the heads of the Departments of War, Navy, Finance, Justice, Agriculture, etc. A fair investigation will show that no profession excels ours in positive efficiency to sustain public order, public comfort and public virtue.

Hygienic science, on the one hand, and the progress of the sciences and growth of the mind, on the other, have always been powerful factors in the evolution of humanity. In the first century, when Rome had reached her apogee in power and civilization, and had constructed great aqueducts, public fountains, public latrines, gymnasiæ and a vast system of sewers, under the suggestions of physicians, Martial said that it was not merely a question of living, for the people, but to have good health; hence the maxim that has come down to us: "The health of the people is the supreme law."

Recently, the Lord Chancellor of England, appointed Sir James Crichton Browne, M. D., LL.D., as his visitor to make certain investigations in regard to the public health, and of the influence of certain employments upon the health, and comfort of the laboring classes. We can only give a partial exhibit of his observations. He found, that while the decline in the death rate at all ages had been, within a certain period, 17.5 per cent. in those under 55 years of age, it had been reduced only 2.7 per cent. in those above 50 years old. The increased longevity has occurred under the age of 35. The decline in the death rate beyond the age of 45 had been insignificant, but from 65 to 75, the death rate was increased. He adds that it is not satisfactory to learn that while there has been an enormous increase in the duration of life in babies and young people, the loss is alarming among those who are eminent in experience and judgment. The causes of this vital failure in the mature element of society was not difficult to find by his statistical studies. In three or four groups of diseases a marked increase in mortality has taken place; thus, in England and Wales, cancer in five years, from 1859 to 1863, carried off 35,654, while in five years from 1884 to 1889, the deaths by cancer were 81,620 an increase of 120 per cent. The increase in deaths by nervous diseases in the same period was 38 per cent.; in kidney diseases for the same period the increase in deaths was 164 per cent.; in heart diseases, the increase was 143 per cent. These affections, he continues, are of degenerative character and largely may be traced to vital abuse, over strain and the increasing luxuriousness in our advancing civilization which establish premature senility. Moreover, the large increase in insanity is causing solicitude everywhere. It cannot be questioned that this fearful increase in bodily and mental decay should be well understood by and placed before the people. There is another

phase of this question of premature decay of great interest and it concerns a burning question of the day. Sir James says, that owing to the strain and drive, in many manufactories where handicraft piecework prevails, the neuro-muscular systems of the shoulder, arm and hand which on the average attain maturity at 30 years, and should continue as much longer, begin to fail at 45 years, and while at 30 a man can earn 45 shillings a week, at 45, strive as he may, he cannot earn over 38 shillings, and at 55 his earnings fall to 24 shillings, owing to the premature decay of the motor apparatus from overwork. In Sheffield he fonnd that penknife makers aged 30 years, strike 28,000 blows a day with a hammer, but at 45, they find their celerity and skill have declined to nearly one-half, and a reduction in wages to the same extent ensues.

As we have no national office for the collection of such statistics, except perhaps the Bureau of Labor in a partial way, we must rely upon those furnished by other nations.

The telegraph operators, everywhere, sooner or latter become the victims of scrivener's palsy of the fore-arm and fingers on account of the excessive use they are obliged to make of them, for, as their celerity fails their wages decline. The mail clerks on railroad trains are required to work many hours more than in other Government offices, and are besides compelled to memorize, with all the certainty of the multiplication table, the locality of eight to ten thousand post offices in the vast districts of the country. The effect in numerous cases of this excessive use of the memory is insomnia and a mild form of dementia. It is, certainly, a function of statesmanship to investigate these serious evils. The Government has begun to investigate the exposure of employes on railroads who are often wounded and killed in the coupling of cars; and the investigation of the desperate use of young people in the "sweat shops" of clothing establishments has created a great outcry for their relief.

"In 1848 the Public Health bills in England went into operation. The annual death-rate which up to that time was 22.5 per thousand diminished to 17.9 per thousand within twenty-years; showing a saving in that time of 125,000 lives. The effect of hygienic measures in preventing sickness is well known in the State of Michigan. During the year 1889 there were 417 outbreaks of scarlet fever. In seventy-two of these outbreaks, isolation and disinfection were neglected and the number of cases, per outbreak, was 16.78 per cent. In fifty-two outbreaks, both isolation and disinfection were strictly enforced with the result of limiting the number of cases to 2.67 per cent. In many outbreaks only one restrictive measure was used and the other neglected, and in all such cases there was some reduction in cases, but never to the same extent as when both were enforced." (Dr. J. W. Brannan, *New York Medical Record.*)

Our census of 1890 shows that 524,000 deaths occurred in that year, and that 100,000 were from consumption. It is estimated that about one-half the whole number was due to diseases that could have been prevented.

It is now becoming generally known that infectious diseases and toxic elements are disseminated in food. An infectious disease in the family of a dairyman, or among his cattle, may be as widely spread as is the distribution of his milk. The pollution of streams supplying towns, cities, and wells of water at farmers' homes, we know, definitely, subject the people to tedious and fatal diseases which a wise sanitation would prevent. It is absolutely demonstrated that by the rigid application of hygienic measures the ravages of a pestilence may be stayed. Medical scientists speak of such destruction as a self-imposed curse of dying in the prime of life.

In primitive history we find that hygeia and therapy were the conservative and remedial agencies of afflicted peoples. We read with admiration of the wisdom which made sanitary measures a part of the religious codes of a nation. The hygienic laws of Moses, which undoubtedly embody fragments of his Egyptian training both as a physician and a priest, and the moral law, the Ten Commandments, received from the hand of God, have been kept together by the Jews in their sacred books and inculcated in their religious and social rites for thousands of years, which clearly accounts for their existence, physically and mentally, as one of the most vigorous races among the multitudes of the earth.

Physicians are held to be the guardians of the organs that concur for the maintenance of a healthy animal life, but it is not so generally understood that the great brain, the physical basis of the mind, is just as much an organ of their conservative regard; it is not so well known that the healthy brain is necessary to a free will—the function that places man in his supreme condition as master of created things.

The increased light which physiology and pathology have shed upon the relations of the brain and mind, has enabled us to locate the area in the brain where exists the capacity to think, where sensations are shaped into concepts, where ideas are symbolized in language, where memory holds its seat, the imagination displays its marvellous powers, and self-control is enthroned. All of the apparatus of our mere animal life—respiration, circulation of the blood, digestion and assimilation of food, excretions of waste tissues and the actions of the nervous and muscular systems are to maintain and develop in perfect health an area which we can cover with our two hands. It is the region of self-consciousness, the plane where spirit and matter are in impact and which enables a man to say: "I know that I know, I feel that I feel, I think that I think;" it is there, indeed, that consciousness feels itself to be coterminate with the cosmos. Who but the physician has the right to supervise this dread region? Closer than the minister of religion, or the rights of family, he stands as the guardian and interpreter of its illimitable faculties.

By prolonged physiologic and pathologic research, psychology has been lifted above the mere subtle reason of the schoolmen into the light of a new day, and is now comprehended as never before. Metaphysics is no longer a mere jugglery with words and phrases, but a function of consciousness only existing in the healthy area above described; it is the highest expression of reason, whereby the intuitional phenomena of thought and the phenomena derived from the senses, the ideal and the real, the subject and the object, the me and the not me, are brought by a free will into accord and the consciousness is freed from the baleful illusions, hallucinations and delusions which exist in the insane. The imperfect state of consciousness in unsound sleep, illustrates a mental state wherein ideas flow freely, regulated only by automatic association; we are led everywhere by the most grotesque and often fearful ideation, without any self-control; the metaphysical function is in abeyance; there is no metaphysics in dreams, the consciousness is on too low a plane for any exercise of the will. This argument is legitimate and should be convincing, that medical men hold an indispensable relation to the social and political state.

All abuses of the appetite in any direction, all violence done to the brain by overwork, overstrain, the excitement of narcotics, and the delirious speculative ventures in the values of stocks and of the products of the crops; everything, indeed, that keeps up, unduly, mental excitement, deteriorates at length the organic structures of the brain, enfeebles the mind in judgment on any subject; in short, a condition of dementia supervenes. It is for the physician to warn teachers of the deleterious effects of overtasking scholars; to warn people against luxuriousness, indolence, and the habitual use of stimulants, and excess in any passion or appetite; for, while the organs of mere animal life are damaged the nutrition of the brain is changed, the will becomes so impaired that self-control is lost. It is appalling to contemplate the social destruction about us on account of the prevalence of the passions of avarice, peculation and lust which so greatly defile public virtue. These are evils the indulgence of which has ruined statesmen and empires. Luxury and vice in combination form the dynamite in the moral world.

The medical supervision should begin in the primary and intermediate schools, which are frequently in overcrowded, ill-lighted and ill-ventilated rooms; this has become so serious that in Germany, at least, it has brought about State interference, and physicians must be consulted in regard to the hygienic properties of a schoolhouse. The physical structure of the eye is most liable to evil changes, leading to short-sightedness; and the organic life of the brain substance is exposed to deterioration leading to lowering of the intellectual faculties. In the technological schools of France the use of tobacco is forbidden, because it has been ascertained that its abuse renders the student incapable o

solving the highest problems in mathematics. It is also of great importance that the methods of teaching should not involve an excessive abuse of the memory —the *memoriter* plan. This it is thought is too greatly employed in American schools, but it seems to be a necessity so long as the rank of a pupil in his class depends upon the rate per cent. of correct answers. The abuse of the memory fatigues the brain as physicians well know, and impairs the power of the free will. Lessons are memorized, and not acquired by efforts of the understanding, hence they are not well retained and furnish a poor basis for intellectual ability. Not only so, but the emotional conditions so often encountered, and the startling phenomena of hysteria and hypnotism are thus often superinduced. There are no fortuitous conditions that concur for the production of the best moral and political circumstances of society; the whole is purposive intelligence existing in the individual and combined in the exigencies of the family and the State. Wherever the highest development of physical health exists, there will be found the surest basis of intellectual life. These are not abstract questions of philosophy but are the most practical questions of our times.

A candid and broad investigation of the medical profession shows that it appertains to the most important functions in the commonwealth. A distinguish English writer has said: "I think it will be well for the state when the medical profession is represented in the councils of the nation as weightily as can be assured by official places and conferred dignities." An eminent German economist has said: "We must look to the medical men to resuscitate society." There are no evils in society which physicians may not do much to avert; there are no foes of human happiness so widespread, miserable and despairing as those which underlie public health; and physicians are the only hope of public relief.

It is certainly a remarkable spectacle, the constant efforts of physicians to save the people from outbreaks of disease, when success will limit to the smallest dimensions our practice and incomes. But this arises from the nature of our studies whose tendencies are to render an unselfish service to humanity in the time of its calamities. The physician is bound to render services to the poor, especially. The amount of gratuitous service in great cities is a very large part of their practice. In all of our public general hospitals they serve without salaries.

If there were cruelties to prisoners on either side in our civil war, it was not perpetrated by the surgeons of the opposing armies. When the strife ceased they were the first to extend the fraternal hand across the red fields of conflict.

The progress of medical science establishes our increasing responsibility to place our medical schools on the highest plane of teaching. There is a very large aspect of medicine that renders it so commonplace as practically to degrade it, and this is a consideration that will be a great obstacle in the way to your adoption of our bill. I allude to the giving of drugs by everybody for the relief of symptoms of disease. It may be said all the people, young and old, not only offer general advice, but specify the remedies to be used. If medicine has no other basis than prescribing, it would possess no autonomy, embody no science, nor philosophic spirit; it would only become an unstable empiricism and would be abandoned to a revolting charlatanism and its practioners be mere vendors of secret, false remedies, and, as is now so largely done, would rob the sick not only of their money but of any hope of relief.

The human frame is said to be the Divine idea of mechanism, and nothing in all the works of creation so completely illustrates in its structure what is called by geometers the "principle of least action," that is, the greatest competency in function, with the least expenditure of material. Its figure, symmetry, mechanical, physical, chemical and biological forces are so correlated that it fulfills all the conditions of adjusting internal to external relations. Its organs of special sense, its area of consciousnese wherein it is the equipoise of the physical creation, justifies the ascription that man is the crown and flower of creation. Can any one doubt that it is only by a long and minute study that such an organism can be comprehended? Congress appropriates annually more than a million of dollars for the maintenance of military and naval schools, where the whole range of sciences are inculcated to ascertain the most ap-

proved methods of public defense and of killing our enemies. Can it be thought that any less science is needed to ascertain how to destroy myriads of enemies that provoke disease, and all the more terrible because invisible to common sight; and to save from death the most precious objects of human love and solicitude? Are there more scientific problems for solution in war by sea, or land, than those that exist in the grievances of our social life?

But we are not asking Congress to build a great medical school of instruction. Congress appropriates willingly large sums for the study of the diseases of cattle and plants, but comparatively nothing for the diseases of the people. But we show you that 522,000 inhabitants died in 1890, and that 250,000 of them at least, have perished by diseases which are preventable!

We ask for a Governmental Department of Public Health; one of whose functions would be the combination of the intelligence, feeling and force of all the schools and medical societies of the nation for collective investigation in order that physicians may become capable to the utmost, to relieve the woe and agony of suffering individuals and families.

For the medical profession to be able to exert all its benign influences in society, it must have the same rank and dignity that is attached to other Departments in the President's Cabinet. The methods of research are the same as those employed by other scientists. The methods of the calculus that are employed to ascertain the cause of the perturbations of celestial bodies, are the same as those employed in the investigation of obscure diseases. The physician is guided in his investigations by the canons of logic, and hence it is that the opinions of well-trained doctors are as reliable and stable as those of jurists, statesmen, engineers, merchants, divines, lawyers and political economists. The same reproach applied to doctors because of their different opinions, applies equally well to all other callings.

At this time the success in medical practice surpasses any other period of its history. The death rate in our general hospitals was never as low. In surgery it is about 3 per cent.; thousands of successive births take place in maternity hospitals, without a single death; the mortality in typhoid fever is about 3 per cent. in hospital practice; in general medicine the rate is declining; but it is not so low as in surgery because of the increasing mortality, as before said, in such diseases as consumption, cancer, kidney, heart affections, and the continued bad hygienic conditions in the congested areas of our large cities, where one-half the children die under five years of age. (Cincinnati Hospital Report, 1893).

The influence of medical culture upon the progress of civilization as before said, both in ancient and modern times forms a great chapter in human history. The evolution of the mind and the achievements in philosophy are no more marvelous than what is seen in preventive and clinical medicine. The chief figure in the most brilliant era of Greek civilization was Aristotle. He was of the Esculapian caste and took up the profession of his father, a practitioner of medicine; but his constant dissection of animals and plants aroused a philosophic spirit of seeking behind all the phenomena of nature by synthetic formula, the unity of all living beings and their indissoluble relation to the cosmos.

We can not, in our space, point out all the achievements of his immense genius nor his specific work in detail that entered into his purpose of constructing the edifice of inductive philosophy. Mere fragments of his precious writings were the only intellectual food (excluding the canon of sacred Scripture and the liturgies of the Church) of the Dark Ages; but when at last the chief of his philosophic works were collected and translated into Latin, the dawn of the revival flushed the skies and the sun of a new mental life shone in full strength upon the scholastic world, —the church adopted his philosophy and the renaissance was complete. The influence of Aristotle has continued to direct modern thought, and though much of it has been laid aside, his inductive philosophy and logical methods are invincible.

In Europe, medical affairs have always had the watchful care of the state, and eminent practitioners are now more than ever before, receiving titles of distinction. In Italy a physician holds a Cabinet Secretaryship, and in the Parliaments, everywhere, distinguished practitioners are taking part in general statesmanship. Without the science of medicine, civilization could never be effective in semi-civilized and barbarous lands.

The conquest of India by Great Britain has been maintained by superior military power; but its present tranquillity is largely due to the beneficent work of medical practice. Since the last great rebellion there, the English and missionary societies of our own country have established fifteen hundred hospitals and dispensaries, and medical schools are increasing in numbers. The light of Christian benevolence is now carried into the hitherto closed doors of the homes of the people. In China the same benign work has taken deep root. Fifty years ago Dr. Parker of the American Presbyterian Church, opened a hospital in Canton, and an immense work has been accomplished in surgical and midwifery practice, for which the Chinese had no remedies at all. Now a large number of hospitals and dispensaries have been planted along the sea coasts and throughout the interior. Besides male, a large number of well-educated female practitioners, are employed in them. It is the most touching spectacle of human sympathy and relief the world has ever known. Were it not for their skill in medicine the American missionaries would be expelled. Japan, Korea, Java and Africa, are being advanced in civilization in the same manner. Dr. Mungo Park and Dr. David Livingston were the most venturous explorers of Africa.

It is the belief of many physicians that if from the beginning of the settlements in this continent the medical office had been recognized as a Department of the State, on a parity with those of War, Justice and the rest, the great tribes of savage races could have been made friendly, and allies, and brought under the terms of a high civilization by the humane influence of our medical men.

Though Congress is voting vast sums for agricultural schools and experimental stations, yet these are above the reach of the great mass of farmers and their adult sons and daughters. They can not leave the fields and the household duties for at least nine months of the year, and they can not pay the expenses incident to college life; but schools of instruction, by means of lectures, demonstrations, drawings and experiments in physics, chemistry, and the structures and the functions of the chief organs of animals and plants, can be readily inculcated by the doctors in medicine who have themselves been taught in this manner. These lectures can be given by physicians during the winter seasons in the towns of the counties and within reach of the farmers' homes, and a central office, such as we propose, would aim to promote this without expense to the Government.

It will be the means of putting new life into the freshest and strongest minds of the people. Every farm would soon become an experimental station; Nature would be seen with new eyes, and the dull and monotonous lives of this most neglected class would become radiant with a new light. This may be counted one of the great influences that will follow the higher education of physicians.

The question may arise, whether such a Department in the Government would subserve the interests of any particular sect or school in medicine? We reply that, amid the apparent disparity in medical practice, there is one true unity and to attain this all true physicians are continually striving. It is evident that there can be but one anatomy, physiology, pathology, chemistry, physics or preventive medicine. The difference among doctors lies in therapeutics or treatment of disease, and as in the past, so for the future, practitioners will use a variety of remedies and in varying quantities, and there will be different modes of management of sick and injured people. With the advance in medical education the modes of treatment will become more unified.

The organism which is called medicine, like every other product of man's constructive genius, is striving to attain perfection, and to accomplish this it must be sustained in all its scientific undertakings by the co-operation of national and state legislation.

We ask each member of Congress who seeks relief for himself and his family in the times of their distress through the most accomplished practitioners of medicine, to consider that his mind is the type of that of millions who constitute the republic; and therefore we ask him to lend his influence to our effort to secure for the people the most highly trained persons in the science and art of medicine.

We hope that it is plain that a Secretary of Public Health would represent the medical consciousness of the nation, and that he would be one to whom we could all

look for the exploitation of measures that will direct continuous scientific collective research in regard to epidemic and endemic diseases, and especially those of a degenerative character; and thus make his department the repository of the most important measures that concern the welfare and comfort of the people; and his duties will steadily grow broader and stronger in adaptability to public needs.

Respectfully submitted on the part of the Committee.

C. G. COMEGYS, Chairman.

---

## A Bill to Establish a Department of Public Health.

*Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled.*

SECTION 1. That there shall be established a Department of Public Health. There shall be appointed by the President from the medical profession, by and with the advice and consent of the Senate, a Secretary of Public Health, who shall be entrusted with the management of the department herein established. He shall be paid an annual salary of $8,000.

There shall be appointed by the President, with the approval of the Senate, an Assistant Secretary of Public Health, at an annual salary of $5,000.

The Secretary of the Public Health shall, with the approval of the President, provide suitable offices for the department, and shall employ such assistants and clerks as may be necessary.

SEC. 2. It shall be the duty of the Secretary of Public Health to obtain through all accessible sources, including State boards of health, municipal authorities, and the Surgeon-Generals of the Army, Navy and Marine Hospital Service of the United States, weekly reports of the sanitary condition of all ports and places within their territories and departments, and he shall publish weekly abstracts of the information thus obtained and other pertinent matters received by his department. The said department also shall, as far as possible, by means of the voluntary cooperation of State and municipal authorities, of various general and special hospitals, sanitariums, public associations and private persons, procure and tabulate statistics of marriage, births (noting those that are illegitimate), and deaths from epidemic, endemic and all other diseases, specifying those of a degenerative character, such as malignant growths, and affections of the nervous, circulatory, respiratory, secretory, digestive and reproductive organs, and from violence, accidents, suicide, murder, and data concerning the fruit of consanguineous marriages and the transmissibility of insane, alcoholic, syphilitic, nervous and malignant types of constitution to offspring, and to evils of race miscegenation. He shall also procure information relating to climatic and other conditions beneficial to health, and especially in reference to the most favorable regions in the United States for the cure or relief of chronic diseases, particularly tubercular consumption. He shall also procure information as to the prevalence and ruinous effects upon the body and mind of intemperance and prostitution. He shall endeavor to ascertain the extent, the origin and classification of insanity in the several States and territories of the country. He shall investigate the state of comfort of the laboring classes in respect to their lodgment, their trades, occupations, the healthfulness of their workshops and the contents of the atmosphere they habitually breathe, and the prevalence of premature degeneration of the nervous and muscular systems by the exactions of piece-work employment. He shall obtain information in regard to the soundness of their food and purity of water-supply. He shall ascertain the ages at which the children of the poor are put to work, and its hindrance to their physicial development, and their lack of common-school education. He shall seek through the the State boards of health, information of the hygienic state of public school buildings respectiug their illumination, ventilation, and presence of noxious elements in the circumnambient air. He shall seek information in regard to the pollution of streams and navigable waters and public and private wells. He shall attempt, through the co-operation of the authorized medical schools in all the States, to promote the most extended and thorough training of students in order to fit them for the responsible duties that devolve upon practitioners of medicine. He shall, whenever an epidemic disease is spreading abroad, or in any country which by commercial or other relations may endanger

the health of the inhabitants of the United States, have power to call a conference of the Surgeon-Generals of the Army, Navy and Marine Hospital Service, and the executive officer or officers of the various State boards of health throughout the country, to consider and advise with him in regard to the best methods to be pursued to protect the country against the invasion of any such epidemic disease, and the results of such conference shall be, by the Secretary of Public Health, communicated to the President and his Cabinet, for such action as they may deem wise and expedient.

Besides the reports of the state of the public health which he shall make from time to time, the Secretary shall make an annual report to Congress, with such recommendations as he may deem important to the public welfare, and the report, if ordered printed by Congress, shall be done under the direction of the department. The necessary printing of the department shall be done at the Government printing office upon the requisition of the Secretary, in the same manner and subject to the same provisions as that of other printing for the several departments of the Government.

SEC. 3. The President is authorized, when requested by the Secretary of Public Health, and when the same can be done without prejudice to the public service, to detail officers from the several departments of the Government for temporary duty, to act under the department of Public Health to carry out the provisions of this act, and such officers shall receive no additional compensation except for actual and necessary expenses incurred in the performance of such duties. When a detail of such officers can not be made, the Secretary, approved by the President, may employ such experts, and for such time and in such manner as the funds at the disposal of the department may warrant.

SEC. 4. That to defray the expenses in carrying out the provisions of this act, the sum of fifty thousand dollars ($50,000) or as much thereof as may be necessary, is hereby appropriated to be disbursed with the approval of the President, under the Secretary of said department.

This act shall take effect sixty days after its passage, within which time the Secretary and Assistant-Secretary may be appointed.

OBLIGING.—Under ordinary conditions he was a man of prominence—but as he ascended the steps of his residence, very early in the morning, it was evident that he desired to be as much otherwise as possible. The cabby was lingering near to see that his charge was safely disposed of for the night. The door opened before the man on the steps could get his key to work, and he was met with the question:

"John where have you been?"

(*Silence*)

"John, where *have* you been?"

He turned to descend the steps.

"Are you going to answer my question?"

"Yesh, my dear, I am. From my pers'nal knowledge I can't give the desired inf'mation, 'n I'm goin' to ask the man that drives the hack."—*Life.*

A FEW workingmen were discussing names of great scientists in Manchester. The name of Darwin cropped up. One of the company, less learned than the rest, said: "Darwen, I kna that place. A've been ther' monny a toime." "Get out, you fooil!" said another. "We're nut talking about the place called Darwen, but the mon. Hevn't ye nivver heerd o' Darwen? Why, if it hadn't been for Darwen we s'ould all hve been chatterin' monkeys, and nut gentlemen, like we are."—*Sheffield Telegraph.*

---

EXPERIMENTS have been tried with a view to ascertain if color has an effect on certain forms of disease. In making this test a number of smallpox patients were placed in a room to which only red light was admitted. The patients were for the most part those suffering from unusually severe attacks, and about half of them being unvaccinated children. In spite of the violent form of the malady, they all made speedy and safe recoveries, with very little fever and but few scars.—*New York Ledger.*

*March 16th, 1894.*

[Stenographically Reported by C. C. Mapes, M. D.]

### APPARATUS FOR PREVENTING AND CORRECTING DEFORMITIES OCCURRING AFTER EXCISION OF THE KNEE-JOINT.

DR. G. G. DAVIS: In the treatment of resection of the knee, flexion often occurs. It is difficult to get firm union in a straight line, and I believe this difficulty is not recognized sufficiently, and efficient means are not taken to provide against it. This is seen not only in private practice, but still more frequently in cases on which operation has been previously done, which afterwards apply at our surgical dispensaries. I am quite of the opinion that effective apparatus of some sort is necessary. I do not know what appliances the other members have used for the treatment of this tendency, but the apparatus which I have found to be the most efficacious has been as follows:

It consists of two iron sides which are joined at the ankle and have a stirrup beneath the foot; on the inner side the upright reaches to the perineum; on the outer, to above the trochanter.

The outer piece is fastened above to a metal hip band passing three-fourths around the pelvis, and lying, like a truss, just below the crests of the ilia. The posterior portion of the leg is supported by the heel in the shoe below and a piece of sole-leather above going around the posterior half of the thigh, from one side-iron to the other and touching the gluteo-femoral fold. Pressure is made on the front of the knee by a padded sole-leather knee-cap fastened to the inside iron by two straps, while its outer side, passing down between the limb and side-iron, is depressed by one or two screws fastened to a plate on the outer side-iron.

Antero-posterior displacement is met by turning the screws and thus forcing the knee backward.

Lateral displacement is met by bending the side-irons in or out, as required, by wrenches.

Any tendency to inversion or eversion is met by twisting the outside iron; just below the hip-joint with wrenches.

A soft leather hip band will not do as it will not fix the brace firmly enough in relation to the pelvis, to prevent rotation. In order to avoid dropping of the toe, while the patient is going around with a high shoe and crutches, the ankle-joint should be fixed by locking it with a screw, which can be removed when the limb is used for walking.

I am averse to using any apparatus, like plaster-of-Paris, that cannot be altered, and conceals the part. I wish to see the limb every week so that if any tendency to deformity shows itself, it can be, at once, met by applying a positive pressure in the proper direction.

#### DISCUSSION.

DR. DEFOREST WILLARD: It seems to me questionable whether the plate upon the outer side will make as much pressure as the pad ordinarily placed in this position.

DR. G. G. DAVIS: It is simply a matter of taste. I prefer the screw arrangement because straps are apt to yield and become loose, while with it the parents can by turning the screw with a key, always keep the pressure firmly applied.

DR. DEFOREST WILLARD: I think a pad would prevent the joint from yielding outwardly and straps are more simple.

---

DR. H. Augustus Wilson presented a

### CAST OF A LEG SHOWING RIGHTANGLE FLEXION AND ROTATION AFTER INCISION OF THE KNEE,

and said:

When I first saw this patient five weeks ago, at the Jefferson Hospital, he said he was fourteen years of age, and that nine years previously he was operated upon at St. Petersburg for what appeared to have been tubercular ostitis. The operation seems to to have been excision of the knee-joint, and it occurred to me it might be of interest to the Section to study the case, showing such serious ultimate deformity. For six months the child walked with crutches, but on abandoning them the leg became bent, and at the end of a year the leg presented the appearance of right-angle flexion.

At the time I performed secondary operation, at the line of the original incision there was an immense amount of callus. In sawing I also found a large amount of callus thrown in the popliteal space. The curve which existed was very large in the upper end of the tibia and flexion seems to have occurred in the callus; the case illustrating one of the unfortunate results of not using

absolute fixation and crutches long enough. From the history of the case I judge that the condition of tubercular ostitis existed something like two years previous to the first operation. It is interesting also to know that at the upper end of the tibia, which was the original seat of the tubercular ostitis, there was a clearly marked cavity, and in the center a fibrous mass of cheesy consistency. I gouged this out and the patient did fairly well until the relightening of the tubercular inflammation. There has been primary union and the inflammation has subsided under the use of iodoform injections. The case is interesting in connection with a number of cases which I reported at the Academy of Surgery, in which flexion took place after incision. (*American Journal of Medical Sciences*, March, 1893).

DISCUSSION.

DR. F. X. DERCUM: As displacement occurs from active flexion of the muscles, would it not be a good plan to excise the joint and then tenotomize the muscles:

DR. G. G. DAVIS: Tenotomy of the muscles would obviate the tendency to deformity occurring immediately after operation, but would have no influence upon deformity occurring subsequently; that is to say, three months, six months, or a year afterwards, because union would have already occurred.

DR. H. AUGUSTUS WILSON: In the paper which I read before the Academy of Surgery I discussed the same question put by Dr. Dercum, and it was the opinion of a number of surgeons that in excision of the knee, tenotomy of the ham-string tendon should also be done, I believe however, that the more rational explanation is that the weight of the leg causes it to drop and it thereby produces flexion. In excision of the knee, an inch is a small amount of bone to remove, and it naturally shortens the action of the ham string tendons. In any event, if posterior displacement takes place, we would expect atrophy, and flexion of the muscles would follow. I do not know if these views are correct, but they are largely advocated.

The explanation of many of these cases of after deformities lies in the condition of the bones themselves. The worst deformities I have found have followed tuberculosis where previously there had been local tissue removed. The real trouble lies in the fact that the supporting apparatus is dispensed with too early. The cases are prone to deformity because the point of union is not true callus; it is of softer nature. I am fully of the opinion of Dr. Willard as to the necessity of using manual force. If the surgeon grasps the limb above and below the joint, there will be little likelihood of breaking any bones.

I have, on two occasions, broken the femur to overcome deformities at the knee, but it was done purposely and in preference to performing osteotomy. Recently I have swathed the leg above and below the knee with steel rods so that all the force was applied to the knee. A steady application of force will very often lacerate the soft tissues and accomplish correction, whereas the sudden application of force is apt to break the leg at the point of the least resistance. There are many of these cases where there is slight flexion, and if it is impossible to get the limb absolutely straight, we must be content with such straightening as can be attained and repeat our efforts from time to time, usually with better functional results than could be obtained by any operative procedures.

DR. F. X. DERCUM: The question occurred to me whether, in cases of fracture occuring above the knee, a false joint ever ensues? And where does separation take place? Also I would like to ask if Koch lymph is at all used now?

DR. G. G. DAVIS: I would like to say a word about the use of the apparatus of Dr. Goldthwaithe which had been exhibited by Dr. Willard, because in it there is an attempt made to exert a force in a manner which has not yet been alluded to. Dr. Willard spoke of posterior luxation and said that in such cases he usually used excision. Ordinarily straightening of a joint is done by simple flexion and extension movements; not only can these movements be made with the apparatus shown to-night, but there is a direct pulling forward of the head of the tibia and fibula. If this apparatus will do that satisfactorily, it will obviate the necessity of resection in some of these cases of sub-luxation, and therefore I would like to hear the results of its trial.

DR. DEFOREST WILLARD: In regard to the employment of Koch's lymph, I have used it in a few cases during its popularity, but they did badly and suppuration quickly resulted; one knee I was obliged to excise and the patient died. I have not lost faith in its use for tuberculosis, but I think it was given to the profession before its properties were fully developed. Future generations will reap the benefit of what is now an experimental stage. It was launched on the world before it had been sufficiently tested and revulsion followed. Careful experimentation for five or ten years is yet necessary; therefore, while I have not lost faith in its ultimate results, I do not now employ it.

In regard to the fracture of the femur, I would say that I have never seen an injury from such fracture. It would be simply an osteotomy and not likely to give a false joint. In attempting to straighten by osteotomy, a knee which is at right angles, it would be possible not to have union strong enough for the transmission of force, and where I do not

get a perfectly straight limb by tenotomy and brisement force, I straighten it as far as possible and then let it rest for six, eight or ten weeks; then do osteotomy of the femur for correction of the remaining deformity. I do not excise under ten years, as I like to get as much growth as possible.

In regard to the question of excision I would say that it depends very largely upon the age of the patient. In young cases I advocate conservatism; in adults I employ more radical measures. As to the deformities which occur after excision, I think that nine cases out of ten are those which arise from too early use of the limb. Five per cent. of the cases relapse even though good union is obtained. I saw to-day a case which I sent home on crutches over a year ago. She returned all the better for the enforced rest, and there is not the slightest evidence of deformity. When I operate upon a joint I keep it at rest and protect it by an apparatus just as long as I feel any doubt as to its full recovery—six months, a year, two years after I feel it to be perfectly solid. I use an apparatus somewhat similar to the one described by Dr. Davis to-night, and its prolonged use is advisable.

As to the question raised by Dr. Dercum, I would say that in severe cases where the limb cannot be brought into a perfectly straight position, tenotomy is desirable. In all cases of deformity following knee-joint disease, it is a matter for consideration whether excision or forcible straightening shall be done. In my experience it is frequently better to forcibly straighten than to perform excision, especially if the subject be young. Within the last few years I have employed open incision of the semi-membranosis and the semi-tendenosis and biceps tendons, and have then applied powerful force, even to an extreme degree, and I have never had rupture of the popliteal artery or veins; have never broken an epiphysis or fractured a femur. Should fracture result, it would make little difference; it is the same as an osteotomy. I do not, of course, under take to forcibly straighten a knee where there is a large amount of tubercular deposit. In children it is a serious matter to excise a knee-joint, for when there is flexion to the amount of a right angle there will result a large amount of shortening.

The amount of force which can be applied by the hands without injury is very great. This winter I have straightened many limbs, which two years ago I should have treated by excision, and they are all doing well. I am thoroughly in favor of the absolute rest which is gained after an operation by the application of plaster cast. The muscles recognize the absolute fixation and as nothing is required of them, they rest accordingly.

I am of opinion that manual pressure is the best. I have here, however, an apparatus made by Dr. Goldthwaithe, of Boston, for the forcible straigthening of knees, especially where there is posterior displacement. I have never used it as I received it only last night. Since I have investigated its possibilities, however, I believe I shall still continue to use my hands. The leverage is most powerful and in strong hands, I should fear serious injury from its use. In adults it is a difficult matter to exert sufficient force and Dr. Goldthwaithe gives a number of cases in which he has been successful with the use of this instrument.

# THE LIBRARY TABLE.

## BOOK REVIEWS.

*A Text Book of the Diseases of Women*, by Henry J. Garrigues, A. M., M. D., Professor of Obstetrics in the New York Post-Graduate Medical School and Hospital; Gynecologist to the German Dispensary in the City of New York; Consulting Obstetric Surgeon to the New York Maternity Hospital; Consulting Obstetrician to the New York Infant Asylum (resigned); ex-President of the German Medical Society, of the City of New York; Fellow of the American Gynecological Society; Fellow of the New York Academy of Medicine, etc. Containing three hundred and ten engravings and colored plates. Philadelphia: W. B. Saunders, 1894.

The author says in his preface that the work is for busy doctors and undergraduates, and that it is his intention to make it a book of quick reference for those who have not time for more elaborate reading, studying or hospital experience.

He forgot, however, in some of his chapters, the fact that many of his operations and procedures are fraught with imminent danger to those upon whom they are performed, and yet he raises no hand of warning, or caution to those who without training or experience may turn to his pages for information.

The chapter embracing electricity, for instance, is one that may cause some enthusiastic, but inexperienced man to do far more damage than he will be likely to do good. Electricity in gynecology by experts is considered questionable by many, and in the hands of the general practioner and student, may do more mischief than can easily be repaired. Still in this volume there is much to be commended.

To one accustomed to gynecological work, the book will be valuable as giving many hints and suggestions—the various modes of

operating by different authors, and in many cases his own views and opinions, based on personal experience, which are sound, and up to the high water mark of the latest and most improved method of the best operators.

Another objection to the work is the failure of the author to give his own views and reasons on all subjects treated. For, wherever he has done so, there is proof of the soundest professional judgment and skill in his methods. Notwithstanding these defects, the book is one of the best now before the profession of the character aimed at by the author. It is well gotten up—the style easy and engaging. The illustrations are accurate and fully demonstrative of the ideas intended to be conveyed, and altogether it is a work that will find a welcome in the library of every physician who reads and studies the works of our best and most progressive men.

G. R. D.

---

*Lectures on Auto-Intoxication in Disease, or Self-Poisoning of the Individual.* By Ch. Bouchard, Professor of Pathology and Therapeutics, Member of the Academy of Medicine, and Physician to the Hospitals, Paris. Translated, with a preface, by Thomas Oliver, M. A., M. D., F. R. C. P., Professor of Physiology, University of Durham; Physician to the Royal Infirmary, Newcastle-upon-Tyne; and Examiner in Physiology, Conjoint Board of England. In one octavo volume; 302 pages. Extra cloth, $1.75 net. Philadelphia: The F. A. Davis Co., Publishers, 1914 and 1916 Cherry street.

Saliva, bile, peptones, alkaloids of digestion and of intestinal putrefaction from normally present bacteria are constantly menacing the organism. Most of these poisons are destroyed by the liver. The antitoxic action of the liver is shown by trituration of an otherwise fatal dose of nicotine with fresh liver and injection of the filtrate into an animal which manifests few serious symptoms. Trituration with muscular tissue has no such protective result.

The author has little faith in the vicarious action of the skin and intestine in renal insufficiency since the perspiration and intestinal juice remove only thirty centigrams of urea per liter, the proportion present in the blood plasma.

The author shows experimentally that fresh, healthy urine is toxic, but no one of its ingredients gives correspondingly toxic results. Urea is fatal only when ten times as much has been injected into the circulation as is found usually in the blood of persons dead of "uræmia."

Bouchard's treatment of typhoid is as follows: (*a*) fifteen grams of magnesium sulphate every three days; (*b*) for four consecutive days, twenty hourly doses of two centigrams of calomel (as antiseptic); (*c*) fifteen c. c. (tablespoonful) every two hours of the following nutrient and antiseptic paste—vegetable charcoal, 100 grams; iodoform, one gram; naphthalin, five grams; peptone, fifty grams; glycerin, two hundred grams; (*d*) injection morning and evening of 500 c. c. of a 1 per mille solution of carbolic acid; (*e*) eight baths daily, the water being originally 2° C. (3.6° F.) below the body temperature, and reduced about 1° F. in five minutes, never below 86° F. The cooling process requires an hour or more. If the temperature is high, large doses of quinine are given every three days; (*f*) a diet of broth with barley, lemonade and the paste already mentioned. Bouchard's mortality rate has been reduced from 25 per cent. to 7 per cent. by this method.

The author emphasizes in detail the importance of stimulating the emunctories and refers to bleeding as a rapid means of elimination of toxines in anuria.

No review can do justice to this work. It is matter for slow reading and assimilation. There is almost no waste of words nor literary padding. In a sense, one is disappointed with the book, as with every other book which contains instead of brilliant generalizations, the results of carefully proven investigations.

A. L. B.

---

*Congenital Affections of the Heart,* by George Carpenter, M. D., Lond. Published by John Bale & Sons, London, W., 1894.

This little brochure of 102 pages gives a very excellent resume of the congenital affections of the heart, and well repays careful reading. The author points out clearly the occurrence of endocarditis rheumatica prior to the age of four months, and refers in an interesting manner to the difficulties of diagnosis at this early age. The various abnormalities of the valves are arranged in tabular form on page 46. In 181 cases of various congenital cardiac affections collected by Peacock, 119 showed malformation of the pulmonary orifice and the cornus arteriosis.

Reference is made to the infrequency of malformations of the arteries, and that the aorta occasionally forms a double tube surrounding the trachea, and that coronary arteries may originate high up in the aortic arch, or be given off by some one of the vessels. In somewhat similar manner two ascending or two descending venæ cavæ are occasionally met with.

The chapter on malformations of the heart is interesting, and, in addition to the transposition of the heart and viscera, reference is made to cases where the heart is situated wholly or in part external to the thorax, or in association with protruded abdominal viscera, and one case is recorded where the heart was found situated near the right kidney.

That these cases also occur in animals is shown by an autopsy made by Professor Harger upon a cow, which had been under observation at the Veterinary Department of the University of Pennsylvania for more than a year. The heart was in the neck, where it had been palpated and auscultated during life.

This book, though small, is full of information, and the twenty-two cases reported are of special value.

J. D.

*Clinical Lectures on Pediatrics.* Delivered in the Vanderbilt Clinic during the session of 1892-93, by A. Jacobi, M. D., Clinical Professor of the Diseases of Children in the College of Physicians and Surgeons of New York, etc., etc. Baily and Fairchild, 1893.

This modest little volume has found its way to my table, and also to my understanding. It is unpretentious in its salutatory, and unambitious in its design, but nevertheless it is far more than the author claims for it. If its pages are opened even when one is tired and sleepy, interest will soon be awakened and the book is sure to be closed reluctantly.

The subjects treated of are such as come to the doctor from day to day, and the clear and well-defined manner in which the author goes into each case as it comes before him is refreshing and engaging, and withal, eminently instructive.

To the busy doctor who has time only to cull a little here and there—I will say he can find here, within the pages of this little volume, more than in many far more pretentious in their make-up. I welcome it to my table and shall often enjoy its perusal.

G. R. D.

---

*The discovery of Modern Anæsthesia. By whom was it made?* A brief statement of facts by Dr. Laird W. Nevins. Published by Geo. W. Nevins, Cooper Institute, New York, 1894.

The most important and valuable discovery of the present century is that of anæsthesia.

There are four claimants for the honor of this discovery. For many years our leading surgical and dental journals were filled with exciting and bitter discussions as to whom the honor belonged; each advocating the claims of this or that individual; and this discussion is now being revived by many of our professional journals.

Dr. L. W. Nevins has written a small volume on the subject, in which he does not advocate the claims of any one of the four individuals named, but has gathered all the facts possible on the subject, and, with an even hand has balanced and weighed the degree of merit belonging to each. He has, in an interesting way, presented the only free, impartial and unbiased statement on the subject which I have ever seen.

The book contains fine portraits of the four claimants named, with a biographical sketch of each, and engravings of the monuments erected to their memory; also a likeness of the two dentists who were incidentally connected with the discovery claimed for Dr. Wells; and a fine portrait of Sir James Y. Simpson, who discovered the anæsthetic powers of chloroform.

All these portraits, together with an enlarged engraving of the Ether Monument in the Public Garden at Boston, have been attractively arranged and produced on a large heavy sheet of paper, 19x24 inches, intended for framing.

The book and the picture should go together; one for the office-wall, the other for the office-table or library. Considering the insignificant price ($1.50) no physician of note can afford to be without them.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

---

THE AMERICAN JOURNAL OF OBSTETRICS for April. Dr. Charles P. Noble contributes a paper on

**Acute Puerperal Cellulitis and True Pelvic Abscess.**

He reports several cases as demonstrating the following:

1. That in the puerperal state pelvic cellulitis and true pelvic abscess occur as the result of septic inflammation.

2. That inflammation may spread from the vagina or uterus along the pelvic lymphatics to the broad ligaments without involving the Fallopian tubes.

3. That peritonitis can be set up by the spread of inflammation from the broad ligaments to the peritoneum without involvement of the Fallopian tubes.

4. That very extensive pelvic exudate and intra-peritoneal adhesions can be absorbed.

The author believes that pelvic cellulitis and true pelvic abscess are comparatively rare conditions, and that the usual variety of pelvic inflammation is a salpingo-peritonitis. He has not met with the pelvic cellulitis except in the puerperal state, and believes that it does not occur except as a result of infected wounds of the vagina and perineum.

**The Aseptic Dressing of the Umbilical Stump**

is the title of a paper by Dr. Joseph Eve Allen. In it the author urges the application of the principles of aseptic surgery to the care of the umbilical cord, reviewing the opinions of various authors as to the dangers of infection. He declares that the process of separation of the cord is one of dessication and not one of suppuration and ulceration. Whenever, therefore, putrefaction, or ulceration appears it is proof positive that the dressing has not been aseptic. The writer's method is to secure the cord temporarily by means of a clamp or ligature till after the child is washed. After this the attendant should make his hands perfectly aseptic by repeated washings with soap and water, and scrubbing with a nail brush, and then finishing with a 1:1000 bichloride solution. The funis and abdomen of the child should be wiped off also with this bichloride solution.

The cord is again cut about an inch and a half from the abdomen and the gelatinous

material pressed out. The bichloride solution must then be again used freely, after which the funis is tied with an elastic silk ligature which has been sterilized by first boiling for half an hour in a 1: 500 bichloride solution and then immersing in a solution of iodoform in sulphuric ether 1: 50. These ligatures after having thus been prepared, should be cut into lengths of about four inches and kept dry in a clean wide-mouthed jar till used. The cut end of the cord should be touched with a bichloride tablet.

The cord is then enveloped in a piece of sterilized gauze, not sublimated, which has previously been saturated with glycerine. Another pad of sterilized gauze saturated with glycerine is then placed over it and the whole held in place by a sterilized flannel bandage. The gauze used in the dressings should not be sublimated on account of the eczema produced by long contact of corrosive sublimate with the skin. Chemically pure glycerine is especially indicated as an application to the umbilical stump, for the reason that it is bland, unirritating and antiseptic, and has great hydroscopic properties, thus hastening the process of desiccation. Cords treated in this way often fall within three days.

In regard to the after-treatment, until the funis separates the bandage should be opened twice daily and the dressings saturated with glycerine. The top pad should be removed daily and replaced by a fresh piece of sterilized gauze. Whenever soiled the flannel bandage should be changed. After the cord falls the umbilical fossa must be filled with aristol, a dry pad of gauze placed over it, and the bandage reapplied. Repeated microscopic examinations of the debris of cords that were treated as above failed to show the presence of any form of microbe.

When the umbilicus ulcerates or becomes infected, the best treatment to be pursued is repeated irrigations with peroxide of hydrogen or a 1: 500 bichloride solution, after which the stick nitrate of silver is to be thoroughly applied, the parts thickly dusted with aristol and covered with a sterilized gauze pad and flannel bandage.

Aseptic precautions should be observed at all times, but especially during the prevalence of epidemics of zymotic diseases, and when the infant is exposed to a contaminated atmosphere such as exists in crowded tenements and hospital wards.

Dr. T. Ridgway Barker describes

**An Ideal Napkin for the Puerperal Woman.**

The napkin is made from cheese cloth and cotton, both baked so as to be rendered sterile. A square is cut from the cheese cloth, nine by nine inches, folded over, making it four and a half inches wide; a piece of absorbent cotton is cut just the same size (four and a half by nine inches), and placed between the folds of the cheese cloth. In this manner is prepared in the simplest possible way a compress which is readily applied and needs nothing to hold it in its place, so closely does it adhere to the skin when the parturent occupies the semi-recumbent position Before applying a fresh dressing the external genitalia and the mouth of the vagina should be bathed with warm water. The patient is given four warm vaginal douches, by means of a fountain syringe, a day during the first week, and thereafter two a day. These serve a useful purpose in keeping up drainage. Should any odor be noticable the compresses may be dusted with powdered boric acid. The addition of a drachm or more of compound spirit of lavender to the water for bathing adds materially to the comfort of the patient.

Dr. T. J. Crofford contributes a paper entitled

**My Experience with Tubercular Peritonitis.**

The author reports a number of operations for the relief of the disease, as the result of which he comes to the following conclusions:

1. Tubercular peritonitis is an operable disease.
2. The immediate danger from the operation is not materially influenced by the character of the inflammation.
3. An early operation is of the greatest value.
4. The chronic or slowly progressing variety offers the best indications for surgical interference.
5. When the primary desposit is in the tubes, an early salpingotomy will cure the disease.
6. Operations later in the disease will frequently prolong life and possibly cure.

Dr. J. T. Binkley discusses,

**The Relations between Salpingitis and Appendicitis Vermiformis,**

reporting a number of cases where abdominal section was performed for tubal and ovarian disease and in which the appendix was found involved. The author divides these cases into two classes: First, those in which the appendix is infected directly or indirectly by the tube; and second, those in which the appendix plants the infection in the tube. In the first class we have the enlarged and inflamed tube presenting an attractive surface to which the wandering appendix may become attacked. As the result of this attachment there may occur a direct infection of the appendix by the transmission of microbes directly through the walls of the tube and the appendix, or the appendix may become infected indirectly by being bent upon itself, or by having exudations thrown about it, causing constricting bands. These bands and bends produce obstruction, and the obstruction causes foreign particles to be retained, and salpingitis naturally results.

The lessons to be learned are: First, that greater care must be exercised in freeing the uterine appendages from adhesions on the right side that on the left; second, that all detached tissue on the right side should be carefully examined with the expectation of finding an adherent appendix, which, if found, should be removed. He strongly advises its removal in every instance where it has once been adherent, because of its tendency to become adherent to various points on the peritoneum.

The author suggests that this body may be responsible for a large percentage of the colic

and reflected pains that follow laparotomies.

The author believes that the chief cause of the downward position of the appendix in women is the shape of the pelvis, which is broad and flaring, and does not have the forward ridge or angle of the pelvic brim under the head of the colon which is found in men. The other factors also favor this position of the appendix: first, the corset, which tends to force it down; and, second, childbirth, which relaxes peritoneal attachments.

Dr. Edward E. Morse discusses, "The Use of Certain Antiseptics in Midwifery," advocating the use of creolin and lysol as being free from poisonous and irritating qualities, and at the same time possessing efficient germicidal properties. He advises the use of a 1: 500 solution of the bichloride of mercury for the hands, followed by their immersion in creolin or lysol solution. By this arrangement the maternal soft parts are quite protected from contact with the corrosive, and the danger arising from such use avoided.

Dr. F. Byron Robinson describes

**A New Method of Treatment of Uterine Myoma without Removal of the Uterus,"**

by litigation of the ovarian and uterine arteries. The author describes a case in which, through an abdominal opening, he ligated the ovarian artery and then applied two ligatures to each uterine artery for about two-thirds of the distance from the tube to the internal os. He did not remove the ovaries and tubes. The patient made a good recovery; an abdominal fistula remained for several weeks.

Three months after the operation the uterus was about two-thirds its former size, and three months later it was one-half its original size. For the past six months the atrophy has been continuous. The patient has had slight hemorrhages but considers herself well. The author has performed the operation three times, and so far with good results. Great care and judgment must be exercised, in the cutting off of the blood supply of the uterus, not to go beyond the limit of safety as regards gangrene. The minimum amount of blood supply necessary for the life of the uterus cannot be stated, but the author has demonstrated that the ovarian artery and the uterine artery for two-thirds of the distance from the tube to the internal os can be safely ligated.

Dr. George J. Lochboehler presents the report of "A Case of Prolonged Prolapsus Funis in Twin Pregnancy." The first child was born alive after the funis had been prolapsed for two hours and a quarter. The second child was born alive a few minutes later. The author believes that this is the greatest length of time for a living child to be born when the cord has been prolapsed.

The remaining papers in this issue are: "Note on Oligohydamnion" by Dr. W. W. Jaggard. There was absolutely no liquor amnii the child being surrounded by a tough membrane and covered with a thick layer of vernix caseosa and a thick, viscid, gelatinous substance. The child was deformed and lived only an hour. The paper is illustrated with photographs of the child.

"Urethral Caruncle" by Dr. Edward Nicholas Liell.

THE MEDICAL CHRONICLE,

of Manchester, Eng., for March. Roger Williams, F. R. C. S., continues his paper on

**Sarcoma of the Breast.**

Pure Sarcomata, he says, seldom originate such large tumors as the adenoid variety though the main features of the disease are very similar to those met with in the latter variety.

In regard to the so-called alveolar variety he state that recent investigation have shown that these growths arise from the endothelial cells of the adventitia of the lymph spaces. If we accept this view of their origin, they should be classed with the cancers, for embryological researches have shown, that the endothelium is a derivative of the archiblast and not of the parablast, to which its origin has hitherto generally been ascribed. There are many facts in the morphology and clinical history of the disease that are best explained from this standpoint. In as much as these growths are highly malignant, they should be freely extirpated, as soon as possible, together with the breast and overlying skin; and the axilla should be cleared as well in every case.

Any form of melanatic neoplasia of the breast is of extreme rarity. The author's table of 2,397 consecutive primary neoplasms of the female breast does not contain a single instance. It appears, however, to be rather less exceptional in the male breast, for of 100 primary cancers of this part collected by the author three were of the melanotic variety.

Myxoma is a rare form of mammary neoplasm, since of 2,397 female cases there were only two examples of it.

In their main features myxomata of the breast closely resemble sarcomata, of which they are evidently but a sub-variety. The chief pathalogical consequence of the histological diversity subsisting between, these two forms of the disease is that the myxomata rarely originate metastases, and that they recur locally after removal much less frequently than the sarcomata. Mammary myxomata acquire to be treated in accordance with the same principles as mammary sarcomata. The prognosis is, however, more favorable, statistics showing that local recurrences after removal are met with only in 16.6 per cent. of all cases.

The author divides Keloid into two varieties: (1) the commonest form, in which the disease usually presents as an oblong, flattened outgrowth from the derma, of smooth, purplish-red aspect, much resembling an over grown irritated scar. When the question of treatment is under consideration, it is well to remember that, having attained a certain size, the disease often ceases to increase. Moreover, under the influence of soothing applications, it sometimes manifests a tendency to spontaneous resolution. Consequently, operative interference, caustic and irritant applications should be sedulously avoided. The best treatment is to cover up the lesion with belladonna, salicylic acid, or ammoniacum cum hydrargyro plaster.

(2) The rare form of the disease is characterized by the formation in the derma of whitish, ivory-like, slightly elevated, indurated areas.

which feel firm and elastic, each being surrounded by a faint, lilac-colored vascular areola. It seems in reality to be a localized scleroderma. If left alone, it generally progresses, but very slowly; and after a time retrogressive changes sometimes supervene spontaneously.

In regard to sarcoma of the male breast, the author states that it may be inferred that all the varieties met with in the female breast may also be found in it, although, of course, such occurrences are of great variety. Most of the recorded cases known to him have been pure sarcomata. In 2,432 cases of primary breast neoplasms analysed by him 99 of which were sarcomatous, there were 2 instances of myxoma of the male breast. A case of mammary adeno-myxoma in a man has been recorded by Obolensky.

Appended to the paper are reports of cases of the various forms of sarcomata described.

In the "Clinic" department, R. T. Williamson, M. D. describes "The Early Pathological changes in Disseminated Sclerosis," reporting a case. The paper is illustrated with wood cuts of sections of softened patches in the grey matter of the cord, and sections of blood vessels.

R. T. Williamson, M. D., reports "A Case of Cerebral Abscess secondary to Pulmonary Disease."

Robert E. Lord, M. D., reports "Two cases Illustrating the Difficulties in the Diagnosis Ulcer." Dr. Lloyd Roberts, M. D. continues his paper entitled, "Further Cases of Ovarian Cystic Tumors" reporting a number of cases.

## NEWS AND MISCELLANY.

### Pennsylvania State Medical Society.

The following is a list of the addresses and papers which have been appointed to be read or have been secured by the Committee on Scientific business for the meeting of the Pennsylvania State Medical Society, to be held in Philadelphia, May 15 to 18, inclusive.

*Annual Addresses.* Medicine, W. S. Foster, Pittsburg; Surgery, G. D. Nutt, Williamsport; Obstetrics, E. E. Montgomery, Philadelphia; Mental Disorders, T. M. T. McKennan, Pittsburg; Hygiene, J. H. Wilson, Beaver; Ophthalmology, Geo. E. de Schweinitz, Philadelphia.

*Medical Papers.* Charles W. Dulles, Hydrophobia; H. F. Slifer, Dietetics; John M. Batten, Unique Cases in Practice; W. C. Hollopeter, Therapeutics of Whooping Cough; William P. Munn, (Denver, Col.,) Colorado Climate for Consumptives; R. G. Curtin, Subcutaneous Emphysema; John Aulde, Diarrhœal Diseases; Wharton Sinkler, Acroparæsthesia; Adolph Koenig, Typhoid Fever; W. E. Hughes, Tapping of Abdominal Effusions as a Therapeutic Measure.

*Surgical.* E. Laplace, Radical Cure for Hernia; F. LeMoyne, Modification of Pirogoff's Amputation; X. O. Werder, Surgery of Gall-bladder; T. S. K. Morton, Section of Tendo Achillis in Fractures and Dislocations; John B. Deaver, Appendicitis; G. G. Davis, Amputation near the ankle; O. Horwitz, Stricture of the Urethra; Charles W. Dulles, Treatment of Fractures at the lower end of the Humerus; J. M. Barton, Acute Intestinal Obstruction; Edward Martin, Ocular Exploration of the Bladder and Urethra; John B. Roberts, Thyroidectomy.

*Obstetrical and Gynecological.* J. C. McAllister, Puerperal Eclampsia; Charles P. Noble, Uterine Fibroids; J. M. Baldy, Acute Endometritis; Anna M. Fullerton, Studies in Obstetrics and Gynecology: Horace Fox, Symphyseotomy and other Procedures; B. F. Baer, Cholecystoenterostomy.

*Eye and Ear.* S. L. Ziegler, Corneal Ulcers; S. Mac Cuen Smith, Diseases of the Ear; H. F. Hansell, Surgical Treatment of Internal Strabismus; Charles H. Thomas, Eye Strain; Charles Burnett, Tympanic Vertigo; Louis F. Lautenbach, Massage Methods in the Relief of Tinnitus; L. Webster Fox, Capsulotomy after removal of Cataract.

*Nose and Throat.* W. H. Daly, Intranasal Surgery; William R. Hoch, Nasopharyngeal Catarrh.

*Skin.* J. V. Shoemaker, Clinical Observations; M. B. Hartzell, Epithelioma of the Skin.

*Tuberculosis.* Arrangements have been made for a discussion on Medical and Surgical Tuberculosis, and papers will be read on Medical Tuberculosis as follows: S. S. Cohen, Curability and Treatment; J. M. Taylor, Physical Phases; A. M. Cooper, Contagiousness; L. F. Flick, Prophylaxis; Hugh Hamilton, Medical Tuberculosis; T. J. Mays, Strychnine Treatment of Pulmonary Consumption; D. Longaker, Case of Tubercular Meningitis.

The following members of the Society have announced their wish to take part in the discussion on Medical Tuberculosis: J. H. Musser, W. B. Ulrich, J. C. Wilson, J. S. Cohen, W. E. Hughes.

The following papers on Surgical Tuberculosis will be read:—C. B. Penrose, Tuberculosis of the Fallopian Tubes; H. A. Wilson, Treatment of Tubercular Caries of the Spine; E. B. Haworth, Case of Tuberculosis of the Knee-joint.

The following members will take part in the discussion of Surgical Tuberculosis:—J. B. Roberts, De F. Willard, G. G. Davis, J. K. Young, J. M. Barton, B. F. Baer.

Tubercular Manifestations of the Skin will be discussed by H. W. Stelwagon.

Besides these, the following papers on general subjects are announced:—Hildegarde H. Longsdorff, Christian Science and the Medical Profession; S. S. Cohen, Should the Journal of the American Medical Association be used to Promote Quackery; E. Jackson, Reasons for the Revision of the Code of Ethics; O. H. Allis, Cramming in Medical Schools.

The Committee has obtained the consent of Dr. Benjamin Sharp, of the Academy of Natural Sciences, to exhibit to the Society his beautiful series of lantern pictures of the Leper Settlement at Molokai, Sandwich Islands, and of lepers in various stages of the disease.

## ORIGINAL ARTICLES.

### THE EXTINCTION OF TUBERCULOSIS.*

GEORGE H. ROHE, M. D.†

This Ninety-Sixth Annual Convention of this Faculty should be to us an occasion of congratulation. During the past year, our losses in membership have been few, and our gains not inconsiderable.

The semi annual meeting held in Annapolis last November was very successful, in point of attendance as well as in the character of the work accomplished.

In an address at the opening of that meeting, I said: "A legitimate object of organization is to use it as a power to secure legislation. Not legislation for our benefit as physicians, but legislation for the public good. The medical profession wants nothing for itself from the Legislature. The legislation in which the profession is interested is such as will be for the benefit of the whole people. Public health laws, medical registration laws, lunacy laws, were all intended for the good of the public, although always originated, and their enactment promoted by, the efforts of physicians.

It gives me especial gratification to call your attention to some recent results of such organization in this State. During the last session of the General Assembly three measures were considered in which the medical profession were interested, and which had their origin in committees appointed by this Faculty. These measures were: The Amendment of the Medical Practice Act, the bill for an Additional Hospital for the Insane, and the Act for the Prevention of Blindness in Infants. Each of them passed in essentially the shape in which it was recommended by the Faculty through its appropriate committees. Having watched the progress of these measures through the Legislature, I believe I may say that not one of them would have passed in satisfactory form if the members of the Legislature had not been impressed by the fact that the organized profession of the State, as represented in this Faculty, endorsed and supported them. In this connection I may be permitted to mention a circumstance which, I think, justifies this statement. When the bill for the prevention of blindness was put upon its passage in the House of Delagates there was a good deal of opposition to some of its provisions. The bill was eloquently and intelligently defended by the Baltimore City delegation and the Committee on Hygiene, but the opposition was so determined that for a time its success was problematical. It was not uninteresting to note that the only effective opposition came from those counties which are still unrepresented in this Faculty.

There is additional reason for congratulation in the fact that all the labor of getting a law passed through the Legislature was not rendered nugatory by unfavorable executive action, as has happened to

*The President's Address before the Medical and Chirurgical Faculty of Maryland, April 24, 1894.

†President of the Medical and Chirurgical Faculty of Maryland; of the American Association of Obstetricians and Gynecologists; Professor of Therapeutics, Hygiene and Mental Diseases in the College of Physicians and Surgeons of Baltimore: Superintendent of the Maryland Hospital for the Insane, Catonsville, Md.

the profession of this State heretofore. Having at present in the executive chair a Governor "noted for his common sense," as was happily said by Dr. Preston, in the discussion on the Care of the Insane at Annapolis, all our bills have been approved and are now laws.

These successes should only render more forcible the appeal of the Committee on Membership for a larger representation of the profession of the State in the Faculty. There is room in this organization for every honorable regular practitioner in Maryland.

I will now invite your attention to some considerations showing the possibility of

THE EXTINCTION OF TUBERCULOSIS.

For over two thousand years a portion of the medical profession has believed in the contagiousness of consumption. A not in considerable proportion of the laity has likewise leaned to this view. So strong was this belief at one time that toward the close of the eighteenth century a law was promulgated in the kingdom of Naples, making very stringent regulations looking to the registration of consumptives, the segregation of the sick in hospitals and the destruction of infected articles. It seems that at the beginning of the present century the prevalence of consumption in Southern Italy was so great that the expression, "See Naples and die," could almost be taken in its literal sense.

About thirty years ago Villemin demonstrated the communicability of tuberculosis by a series of experimental inoculations upon animals. The results obtained by this investigator were soon confirmed by Chauveau and others. It was, however, not until the epoch-making discovery of the tubercle bacillus by Robert Koch, in 1882, that the value of the researches of the two distinguished French experimenters was generally recognized. Since that time the view that tuberculosis is an infectious and communicable disease has gradually pervaded the profession until to-day there are probably few physicians laying claim to common sense and current knowledge who would attempt to controvert it.

Coincidently with the general acceptance of the infectious nature of tuberculosis have come experiments to more definitely indicate the common methods of infection, and endeavors to restrict the disease within narrower limits. That this is a laudable striving must be conceded when we reflect that the annual mortality from tuberculosis in its various forms in the United States is 163,500, or nearly 450 per day; and that in this city the deaths from consumption of the lungs alone reach nearly twelve hundred per year, a ratio of 13.69 per cent. to the total mortality. If the deaths from tuberculosis in its various forms were included, the ratio would amount to over fourteen per cent., or one in seven, which is the ratio throughout the world, as stated by Koch in his memorable paper announcing the discovery of the *bacillus tuberculosis*.

In accepting the infectious nature of this disease, we must not overlook the influence of the receptive condition of the individual in determining the time or place of infection. While the value of hereditary predisposition in determining phthisis is often over-estimated, we cannot ignore it altogether; neither may we undervalue the effect of an acute or chronic inflammation, a traumatism, or other weakening factor in rendering the tissues less resistent, or more receptive to the infective agent. These and many other conditions governing the infection of the individual must be recognized and accorded their full worth. The essential fact remains, however, that without the inoculation of the bacillus tuberculosis we cannot have consumption, or any form of tubercular disease; and if by any means we can exclude this infective agent from the body the individual is safe from the disease.

There are two principal channels of infection in tuberculosis; one is by the digestive tract and the other, far the more important, by the respiratory organs.

Children are especially liable to infection by way of the digestive organs. An infant nursed by a consumptive mother, or one fed on milk from tuberculous cows, may become tuberculous if the food contains the infective agent. It has been shown that the milk may contain tubercle bacilli, even though there is no recognizable local tubercular disease of the lacteal glands. It is highly probable that the frequency of tuberculosis of the intestinal canal, the peritoneum, the mesenteric glands and other abdominal organs in the young, is in most cases attributable to direct infection by tuberculous milk. In the adult this avenue of infection is likewise open. Meat from tuberculous ani-

mals, or other articles of food accidently contaminated by the tubercle bacillus, may be the medium of communication. Secondary infection, from swallowing the bacillus-laden sputum from the lungs, is also not infrequent.

I need hardly say, however, that in the great majority of cases of tuberculosis the infection takes place by way of the respiratory organs, which also become the principal, and generally the only, seat of the disease.

It is held by some, and I am inclined to consider the belief well founded, that the tubercle bacillus cannot effect a lodgment in the tissues and begin its destructive action, unless these are weakened in their resistive power by an inherited defective organization, or by acquired conditions of lowered vitality. It is a result of clinical observation that a catarrhal pneumonia, for example, is often a forerunner of pulmonary consumption. It is assumed, with good reason, that the anatomical elements of the lining membranes of the inflamed air-cells and finer bronchial tubes succumb to the attacks of the invading germ, carried in the inspired air, while in a state of health the tissues could resist the destroying organism. This simply emphasizes the importance of avoiding any factors tending to depress the vital condition of the organism or any of its parts.

The tubercle bacillus does not multiply under ordinary conditions outside of the body, and the fully developed organism when removed from the conditions favoring its growth in the body soon loses its vitality. But the spores of the bacillus, or the germs of the germ, as one may say, are extremely resistant and retain their power of growth and development for a considerable period. The dried spores are thus always potential sources of mischief if accidently taken into the system by inhalation or swallowing. They may also be inoculated in wounds or traumatisms, but this mode of infection is comparatively rare, and may be left out of account in the present discussion.

Careful investigations by Baer and Cornet have shown that the death-rate from consumption is four times as great in German prisons as among the free population of the same age. In convents, asylums, and similar institutions, tubercular diseases are also extremely prevalent. In the Maryland Hospital for the Insane, over thirty per cent. of the deaths are due to tuberculosis. I am confident that within the last two years at least three patients contracted the disease by infection in the wards. Efforts have been made recently to minimize this danger.

Dr. Lawrence F. Flick has shown by a patient and laborious study of the cause of death in the fifth ward in the City of Philadelphia, that certain houses in that ward are infected. He found that for a period of twenty-five years, from 1863 to 1887, all the deaths from tuberculosis in the ward occurred in less than one-third of the houses, while in 1888 over one-half of the tubercular deaths occurred in these same houses, demonstrating beyond a doubt that these houses were infected.

I can hardly think it necessary to adduce proof that the tubercle bacillus is in all cases of tuberculosis the active agent of the infection. Recent investigations, especially those of Cornet, have shown the manner in which infection occurs. The breath of consumptives contains no bacilli, and is not infective. Even when the lungs are full of broken-down tissue swarming with bacilli, the latter are only in the rarest instances, if at all, exhaled in the breath. Of course, during a fit of coughing, small particles of pus and secretion containing bacilli may be carried along in the forcible expulsion of air from the lungs, but even this is probably rare. Ordinarily the air of rooms or of hospital wards occupied by consumptives is free from bacilli and may be breathed with impunity. It is only when the dust of the room, containing dried and pulverized sputa, is disturbed by sweeping, or shaking up the bed-clothing, or in other ways, that danger of infection occurs. Scrapings from the walls of rooms occupied by consumptives, inoculated into animals, produced tuberculosis in twenty per cent. of the latter. Control experiments showed that dust from the walls of houses, hospital wards and public buildings not inhabited by tuberculous patients was not infective. Cornet showed also that the dust from the walls was in no case infectious when sputum cups were used to receive all expectoration was full of bacilli. Praussnitz has demonstrated the presence of tubercle bacilli in the scrapings of the interior of railway carriages on one of the German railway lines carrying many consumptive passengers. Thus is experimentally de-

monstrated a danger to which attention had previously been forcibly drawn by Whittaker, Gihon and others.

It is generally agreed among physicians that if the stools from a case of tpphoid fever are disinfected before being thrown out where they may contaminate the drinking-water supply, there is little if danger from further infection. The alvine excreta being recognized as containing the infective agent, the destruction of the latter renders the material innocuous. In like manner it may be accepted as demonstrated by recent researches that if the sputa of a case of consumption be disinfected as soon as expectorated the consumptive patient is no longer a source of danger to his neighbor.

From the foregoing it becomes evident that the principal measures of prophylaxis against tuberculosis must be such as comprise, first, immediate destruction of the bacillus tuberculosis in the sputa, or in other excretions when the case is not a pulmonary one; second, the disinfection of clothing and bedding, or other furniture liable to be contaminated with the infective material. As accessory measures must be considered notification to the health authorities of all cases of consumption, public disinfection of infected houses and conveyances (ships, railway cars) and the establishment of special hospitals for the free treatment of indigent consumptives.

The first example of an attempt at a thorough-going restriction of tuberculosis is the decree of the King of Naples in 1832, before referred to. According to De Renzi, quoted by Flick, this decree contained the following propositions:

1. The physician shall report the consumptive patient, when ulceration of the lungs has been established, under penalty for the first offence of 300 ducats, and upon repetition, of banishment for ten years.

2. An inventory shall be made by the authorities of the clothing in the patient's room to be identified after his death, and if any opposition shall be made, the person doing so, if he belongs to the lower class, shall have three years in the galleys or in prison; if to the nobility, three years in the castle and a penalty of 300 ducats.

3. Household goods which are not susceptible shall be immediately cleansed and those that are susceptible shall at once be burned or destroyed.

4. The authorities themselves shall tear out and replaster the house, alter it from cellar to garret, carry away and burn the doors and wooden windows and put in new ones.

5. The sick poor shall at once be removed to a hospital.

6. Newly built houses cannot be inhabited before one year from their completion, and six months after plastering has been finished and repairing has been done.

7. Superintendents of hospitals must keep in separate places clothing and bedding for the use of consumptives. Other severe penalties are threatened to those who buy or sell objects which have been used by consumptives, to servants, members of the family, and to any transgressors whomsoever.

The discovery of the bacillus tuberculosis and its mode of propagation and transmission would almost seem to justify these harsh regulations. Indeed, their enforcement appears to have produced a marked reduction in tuberculous diseases. Dr. Flick, who has made a very thorough study of this question, estimates that in 1782 the mortality from tuberculous diseases in the Kingdom of Naples was ten per thousand of population. In 1887 the official statistics for the Italian States formerly comprised under the Neapolitan Kingdom showed that the death-rate from all forms of tuberculosis was only 2.05 per thousand living people.

The efficient carrying out of restrictive measures against consumption requires intelligent coöperation on the part of the public. Hence, the education of the laity upon the infectious nature of tuberculosis and the importance of individual measures of prophylaxis must precede any successful enforcement of the legal enactments looking toward the restriction of the disease. There can be no doubt that the public press can give most effective aid in spreading such knowledge. The newspapers are always foremost in the dissemination of useful information. The press is the most powerful auxiliary of the sanitarian. The press makes public opinion. Public opinion makes laws, and until laws have the sanction of public opinion, it is futile to look for their successful enforcement.

Popular societies, like the French "Ligue prèventine contre la phthisie pulmonaire," and the "Pennsylvania Society for the Prevention of Tuberculosis," are

also useful and effective agencies in educating the people upon this subject. The organization of similar societies should be encouraged elsewhere.

Our current knowledge of tuberculosis and its means of prevention was effectively summed up in a report made to the New York City Health Department in the early part of 1889, by Drs. T. M. Prudden, H. M. Biggs, and H. P. Loomis, the pathologists of the department, and extensively published. In 1890, the Prussian Government issued a set of regulations which admirably cover the whole subject. This action was followed by the Kingdom of Wurtemberg in 1892. In the same year the State Board of Health of Michigan issued a pamphlet giving instructions for the disinfection of sputa, and in 1893 the same Board went a step farther and adopted a resolution requiring consumption of the lungs and other tubercular diseases to be reported among "the diseases dangerous to the public health," this report to be made by householders and physicians to the local health officer as soon as the disease is recognized. The purpose of such report is to secure to the health officer information of the location of each case, "with the view of placing in the hands of the patient reliable information how to avoid reinfecting himself or herself, or giving the disease to others, and and in the hands of those most endangered, information how to avoid contracting the disease."

The publication of the report of Drs. Prudden, Biggs and Loomis seems to have been the first official notification to the public by any health authority of the infectiousness and preventability of tuberculosis, since the Neapolitan decree before quoted. Within a few months the New York Health Department has taken a more aggressive step, and now requires "all public institutions, such as asylums, homes, dispensaries, etc., to transmit to the Board of Health the names and addresses of all persons suffering from pulmonary tuberculosis within seven days of the time when such persons first come under observation." Physicians are requested to notify the Board of all cases coming under their professional care. Hospital authorities are urged to separate consumptive patients from those sick of other diseases. Special inspectors are appointed to visit the residences of consumptives, deliver printed instructions containing methods of prevention, and practice disinfection when required. One of the municipal hospitals is to be set aside as a "Consumptive Hospital" for the exclusive treatment of this disease, and whenever requested by physicians, the Health Department will undertake the bacteriological examination of the sputum in doubtful cases.

Action in a similar direction was contemplated by the Board of Health of Philadelphia, but objection on the part of some physicians to the compulsory notification of the disease was strong so that it has been for the time abandoned.

Within two months the State Board of Health of Washington has placed consumption among the diseases required to be reported to the Board.

The Board of Health of the City of Baltimore is about issuing a circular to the public, giving suggestions in reference to preventive measures against tuberculosis.

The Pan-American Medical Congress in session in Washington last September, adopted resolutions recommending to the various National Governments represented, effective measures for the restriction of the disease, and the American Public Health Association, which has been studying the question for the past four years through a special committee, set its stamp of approval upon the work of the Committee, by the adoption of the following report and recommendations in Chicago last October:

1. "Tuberculosis has been conclusively demonstrated to be contagious, by bacteriological experiments, by clinical observations, and by a study of the history of the disease.

2. "Tuberculosis is a preventable disease. Its preventability follows as a logical sequence upon its contagiousness, but has likewise been demonstrated in practical life.

3. "The contagium of tuberculosis resides entirely and solely in broken-down tubercular tissue. A person suffering from tuberculosis, therefore, does not become a source of danger to others until he begins to give off broken-down tubercular tissue, either in the form of sputa from the throat or lungs, diarrheal discharges from the bowels, or matter from a tuberculous sore such as lupus, white

swelling, cold abscess, scrofula or tubercular inflammation of a joint.

4. "A person suffering from tuberculosis can be made entirely harmless to those about him by thorough sterilization of all broken-down tissue immediately upon its being giving off. With proper precautions it is therefore possible to live in the closest relation and upon the most intimate terms with consumptives without contracting the disease.

5. "Tuberculosis is not hereditary. A predisposition to the disease can be transmitted from parent to offspring, but this is more true of tuberculosis than it is of all other contagious diseases.

6. "A predisposition to tuberculosis can be created anew by malnutrition or by anything which depresses the nervous system.

7. "Tuberculosis affects animals as well as man, and is identically the same disease in both. In domestic life human beings and animals mutually infect each other.

8. "The media through which human beings are ordinarily infected by animals are milk and meat.

9. "Houses in which consumptives have lived and in which immediate sterilization of all broken-down tissue has not been practiced, are infected houses and are liable to convey the disease to subsequent occupants.

10. "Spitting upon floors and into handkerchiefs, and permitting the broken-down tissue to dry and become pulverized, is a prolific cause of tuberculosis.

11. "Temporary occupation of hotel rooms, sleeping car births and steamer cabins by consumptives in the infectious stage can infect them so as to convey the disease to subsequent occupants, unless proper precautions are taken against contamination of the bedding, furniture and walls with broken-down tubercular tissue."

We recommend the following practical measures for the prevention of the disease:

1. "The notification and registration by health authorities of all cases of tuberculosis which have arrived at the infectious stage.

2. "The thorough disinfection of all houses in which tuberculosis has occurred, and the recording of such action in an open record.

3. "The establishment of special hospitals for the prevention of tuberculosis.

4. "The organization of societies for the prevention of tuberculosis.

5. "Government inspection of dairies and slaughter-houses, and the extermination of tuberculosis among dairy cattle.

6. "Appropriate legislation against spitting into places where the sputum is liable to infect others, and against the sale or donations of objects which have been in use by consumptives unless they have been thoroughly disinfected.

7. "Compulsory disinfection of hotel rooms, sleeping-car berths and steamer cabins which have been occupied by consumptives, before other persons are allowed to occupy them."

The City of London Hospital for Diseases of the Chest, the North London Hospital for Consumption, the Royal National Hospital for Consumption, the National Sanitarium, the Manchester Hospital for Consumption and the Victoria Dispensary for Consumption, issue instructions to be observed by their patients to prevent spreading the disease. These all comprise the use of spit cups, disinfected cuspidors, the prohibition of expectorating on the floor indoors, or on the ground out of doors, and the avoidance of swallowing the sputa to prevent reinfection.

In the various sanatoria for tuberculosis in Germany and in many in this country similar instructions are issued. Some progressive private practitioners in this country have had cards printed containing concise instructions for the disinfection of sputa, and other measures to prevent the further spread of the disease.

The various practical measures for the restriction of tuberculosis may be summed up as follows:

1. Notification to the health authorities of all cases of tuberculosis, more especially of tuberculosis of the lungs. This report should be made by the physician who becomes cognizant of the case in the line of his professional duty, and by the householder himself. In order to reach all cases, such notification should be compulsory. While it is probable that some cases would escape report through the negligence or willful disregard of the medical attendant, these would be few and would diminish as soon as the benefits accruing from attention to this regulation became apparent.

2. All public institutions, as hospitals, prisons, schools, asylums, etc., should be required to promptly report through their managers or executive officials, under penalty, all cases of tuberculosis occurring in such institutions.

3. Upon the recovery, death or removal of a consumptive from one house or apartment to another, notice should be given by the patient or his guardian, the householder or the physician, to the health authorities, in order that appropriate measures of disinfection of the vacated premises may be taken.

4. Concise instructions for the guidance of patients with pulmonary consumption, or persons coming into frequent contact with them, should be furnished free of charge by the health authorities, upon notification of a case, or at the request of any person interested. These instructions should cover especially the means for destroying or rendering innocuous the sputa. The isolation of patients is not necessary; when the material containing the tubercle bacilli—in these cases the sputa—is destroyed, the consumptive is no longer dangerous to his most intimate associates.

5. The health authorities should be empowered to employ special inspectors to visit all cases of consumption reported, instruct the patients themselves and the family, or those brought closely and constantly in contact with them in the best means of avoiding self-infection and the communication of the disease to others, and to disinfect the apartments occupied by the consumptive if found necessary. It may be objected that this will interfere too much with the rights and privileges of the attending physician, but the latter would doubtless often be willing to be relieved of the tedious details necessary. There could, of course, be no objection to the attending physician performing these duties himself, provided they were thoroughly done.

Neither the inspector nor any other officer of the health department should be allowed to comment on the physician's treatment or to offer any suggestions in this particular. I believe it will be generally conceded that sanitary officials conduct themselves with tact and discretion in their relations with physicians.

6. Municipalities should be urged to establish special hospitals for the treatment of indigent consumptives. General hospitals should provide special wards for patients with this disease, and enforce in them the proper measures for the limitation of infection.

7. Railway and steamship companies should be required to change and disinfect all bed linen and other materials liable to infection from consumptive travelers.* Dr. Albert L. Gihon, in an address before the Pan-American Medical Congress, has graphically referred to the danger in steamship travel with consumptives, and Dr. J. T. Whittaker has pointed out the many sources of possible infection in the Pullman car.

Such are, in outline, some facts and suggestions that I have thought not inappropriate to present to you on this occasion. The facts are vouched for by leading investigators, physicians and sanitarians. The suggestions are legitimate deductions from the facts recorded. No one who studies the question without prejudice can resist the conviction that tuberculosis, "the great white plague" is a preventable disease; that by concerted action on the part of physicians, sanitary authorities and the public, it can be stamped out among all civilized peoples; that, like leprosy and the black death, it should be of interest in the future merely to the historian of human progress.

---

THE STUDENT WAS PASSED.—Professor Rudolf Virchow, rector of the University of Berlin, is a small man with a dry, parchment-like skin and wears very powerful spectacles. The clothes that the learned professor wears are sometimes such as no old-clo' man would invest in. On one occasion he began the examination of a student by abruptly asking: "What color is my coat?" The student paused for a moment, and then replied: "Apparently, Herr Professor, it was originally black. Now, it seems to be of a bluish tint," for which reply he was passed.—*San Francisco Argonaut.*

---

SUCCESS AT LAST.—"You say she tried to stop a street-car by whistling at it. Did she make a success of it?"

"Yes, in a way. It wasn't her whistling that stopped the car, though; it was the face she made."—*Indianapolis Journal.*

---

* It is reported that on one of the Hungarian railway lines, special railway cars will be furnished for consumptives. These will be renovated and disinfected after each trip.

# THE TREATMENT OF SCOLIOSIS, AND THE BRANDT METHOD OF PELVIC MASSAGE.*

MATHILDA WALLIN, M. D., New York City.

As I am not able to enter into details, nor would be able to give a good description of the movements generally used in the treatment of scoliosis by medical gymnastics, I thought a practical demonstration would be best, as Dr. Lewis has kindly provided me with a scoliotic patient.

The fact that the treatment of scoliosis with bandages and apparatus only is not sufficient for cure of this disease, is more and more realized. . "If we cannot *make* a spinal curvature straight, we can possibly compel it to *grow* straight," and this is done by no other means so well as by medical gymnastics, *i. e.*, exercises arranged to suit each individual case, which will correct the faulty carriage and develop the whole muscular system, combined with the necessary supports. And if a scoliosis is taken early enongh it can be cured. The condition which is the most injurious to health, the most disfiguring, and the hardest to affect by any treatment, is where rotation of the vertebræ has taken place. But even this kind of scoliosis, if discovered early and placed under treatment, can be stopped in its development, and even be cured.

The best results in the treatment of scoliosis I saw obtained were at Dr. Tidemand's Orthopædic Institute, in Christiania where the so called "self-correcting, or self-straightening method" was used. Besides these "self-straightening" movements, by which the patient herself, by her own effort of will, straightens the spinal column. Swedish medical gymnastic movements are given, and the patient rests on a hard bed after each set of exercises; the whole Institute being ideally arranged to carry out the treatment. This treatment is hardly known outside of Norway.

Dr. Zander, whose remarkable genius has been at work even in this direction, has invented some excellent machines for the treatment of scoliosis, which ought to and do give splendid results. His apparatus for measurement of the body and of the spinal column, in order to obtain correct diagnosis, is the best, the most correct, and the most ingenious that was ever invented, and no orthopædic hospital is complete without it.

I want to say a word concerning the prevailing idea that slight degrees of scolioses only need general straightening exercises, equal for both sides, which can be given in a gymnasium. I think that is wrong. Even in Sweden, where there are no other than trained teachers in gymnastics, who have, at the same time studied medical gmynastics, it is not done.

The use of massage and movements as therapeutic means in gynecology was first introduced by Major Thure Brandt, who is one of the most meritorious Swedish gymnasts now living; he has for over thirty years, with indefatigable care, used, and more and more developed the discovery he made, and forced it, so to speak, through hard and energetic labor, upon the attention of physicians. The distrust and suspicion he met from the medical world, in whose "more worthy and skillful hands" he, in vain, tried to place his discovery, did not diminish his energy and courage, but he was compelled by the hostile position of physicians to work on independently and alone, carry out his researches, enlarge his experience and improve his technique. In 1872, his work was to be subjected to an impartial and scientific test by Dr. Sköldberg, a gynecologist of great promise and ability; but he died suddenly just as he was to begin his examination of the work. After that, Brandt, with persevering energy tried to introduce the method among physicians, although with no great success until 1886, when the test—objective, impartial, and scientific—was given to this treatment. Then Brandt, at the proposal of Dr. Profanter, went to Jena, and there under the careful control of Professor Schultze, treated a number of cases personally by his own method.. The published results—which are to be found in Dr. Profanter's book, *Die Massage in der Gynäkologie*—show that it stood the test and was given the recognition it deserved. Having had the great privilege of being Major Brandt's pupil and assistant for

* Read by invitation before the Philadelphia County Medical Society, March 28, 1894.

three years, I consider it a means of showing my appreciation and gratitude to be able to speak to you this evening. In trying to spread the knowledge of this most valuable means of treatment in gynecology by calling the attention of the profession to the subject, I am enabled to pay some of the debt I owe this remarkable man for what he has patiently and kindly taught me.

In this work of Dr. Profanter's you will find that he claims for Brandt's treatment a value above every other, but it remains to be made clear *when* this treatment is advisable and also to familiarize specialists with its technique.

The question whether the technique can be so described in print that a physician can appropriate and make use of it without actual demonstration has often been discussed, and I dare not venture to say that it is absolutely impossible. The treatment is difficult. It is difficult because a great deal of practice is required to familiarize ones self with it, and, after the theory and practice are acquired, it is still not only difficult but exhausting. Then, too, it requires judgment to adapt and moderate the treatment to the nature of the case. I am inclined to think that the reason why so few who have tried the treatment have been successful is because they have not had sufficient experience in its technique. They have thought themselves competent after a week or a few weeks' study with Brandt, and after trial with a few cases, to render a verdict on the method.

It has been considered impossible that Brandt, a layman, should be able to carry out a treatment of any value, which every physician ought to be able to do better. I think that Dr. Lindblom—one of Brandt's pupils—is right when he says: "If Brandt had not been a layman he would not have made his discovery, or, if he had made it, he would not have pursued and developed it as he did. His ideas would then have probably been confined to the certain paths of professional investigation and his treatment adapted to the existing status of gynecological science."

His theoretical knowledge is far from mean, and his ability to quickly and accurately palpate the pelvic organs, and there find deviations from the normal, every specialist has reason to envy. Being self-educated in this line, he has been prevented from entering into the whole scope of gynecology, not to say of medicine, so he is often lacking in ability to give a scientific differential diagnosis sufficient to satisfy a fastidious man of science; but in diagnosis by palpation he is a *master*. He does not, as some writers affirm, claim great and wonderful results for his treatment, nor that his method is a universal remedy for the diseases of women. I have seen him again and again send patients away whom he found on examination he could not help. As for his claiming wonderful results, everybody who has had the fortune to know Brandt says that he is a most modest and humble man, equally willing to give and to receive information.

Brandt's method consists in general and special treatment; the first is not considered necessary by many physicians, but Brandt himself, as well as those who have used the treatment for a longer time, consider it a most valuable adjunct. Many patients suffer from other complaints besides the pelvic disease which the general treatment by medical gymnastics improves and cures; and this may be one of the reasons why in Brandt's patients the subjective improvement is quicker than an objective examination would indicate. In the selection of movements for the general treatment, their effect upon the pelvic organs is first considered, and no movements are chosen which would in any way counteract the effects of the special treatment.

Brandt's method of examination differs somewhat from the ordinary. The patient is always first examined in the standing position, by which the physician is enabled to ascertain the lowest position of the uterus, as it is by its own weight, and by the parts above, pressed downward, and is then in some measure easier to palpate. In some cases the uterus is retroverted when the patient is lying down, and anteverted when she is standing, which he is able to find out only by this mode of examination. Then the patient (with her clothing unfastened around the waist, but otherwise perfectly covered) is placed upon a couch slightly lower than the chair on which the physicians is sitting, her head raised, her legs flexed and abducted, thus relaxing the abdominal walls. The physician sits on the patient's left side, near her pelvis with the face turned toward

that of the patient. Then his left forefinger is passed under the left thigh of patient into the vagina up to the posterior cul-de-sac, thus enabling him to palpate the organs, ascertain their position and condition, lift the organs or parts that require massage, and support them against the abdominal wall and the right hand by which he manipulates externally. The left hand is held open, that is, the three last fingers are placed under the buttock, or along the perineum (because in this manner he is able to reach higher), the thumb to the side, removed from the symphysis pubis, the forefinger pressed as far as possible against the posterior wall of the vagina and kept immovable in the vagina. By the three middle fingers of the right hand, the operator then makes pressure through the abdominal wall, executing the different manipulations indicated by the pathological conditions, and which will be described later. In young persons and virgins, the needed support in the treatment is given by placing the forefinger in the rectum instead of the vagina.

Brandt prefers and uses the low couch instead of the ordinary table, because it is less fatiguing to sit and have the patient lower than himself, thus giving freer motion to his arm and enabling him to work without getting too quickly tired.

The special treatment consists of—

1. Massage of different varieties.
   - *a.* Vibrator pressure or strokings.
   - *b.* Small circle kneadings or strokings.
   - *c.* Large kneading or roll kneading.
   - *d.* Vibratory pressure—strokings.
2. Stretchings.
3. Reposition: different varieties or methods.
4. Lifting { *a.* Uterus. *b.* Sigmoid flexure.
5. Movements for constipation (if indicated.
6. Complex of derivative and inciting movements.
7. Knee abduction.
8. Nerve movements.

Massage should be begun very lightly and at the first *never* directly on the diseased part, but on surrounding parts and on the side nearest the vascular centre, so to stimulate the vessels to greater activity and insite greater resorption of the exudative residues. Brandt always strongly emphasized "rather too little, than too much." The lighter massage, the small circular kneadings, are produced by the three middle fingers of the external hand (care being taken to use the soft parts of the finger tips) pressed lightly through the abdominal wall on the organs within the pelvis in such manner that the integument and underyling tissues follow the fingers. The organs must be supported and sometimes somewhat lifted in order to meet the external hand, by the finger introduced in vagina or rectum, as the case may be. The circular kneadings are produced by small, quick, circular movements of the finger tips, at the same time gradually advancing, if possible, in the centripetal direction of the lymph-currents, using simultaneously all the joints of the arm, which makes the movements lighter and, so to speak, softer, and does not so much actually knead as squeeze and soften the exudates or residues which may be present.

The massage should be begun with light pressure, gradually increasing somewhat, and ending by some lighter strokings and letting the hand rest a few moments on the abdomen, which seems to disperse the unpleasant feeling the movements may have produced.

Indications for the lightest massage are:

1. Menorrhagias in which the whole uterus is masséed, though only for a short time; the treatment may be repeated more than once a day.
2. Atrophy of corpus or of isthmus; the atrophied parts being masséed.
3. Chronic endometritis.
4. Before and after the uterine liftings.

The indications for relatively stronger massage are:

1. Peri- and parametritic exudates or exudative residues, in which case we begin the massage at the periphery, especially on the side toward which the lymph-vessels go, and later, going gradually toward the centre.
2. Adhesions and sensitive scar-retractions in the connective tissue.
3. Massage is also always given after stretching on the stretched part.
4. Chronic metritis; the massage in these cases is executed on the corpus from the fundus toward the isthmus, from the sides toward the middle, and on the cervix from downward up, besides on the broad ligaments partly along the sides of the uterus, partly from uterus toward the sides of pelvis.

If possible, during the massage of the uterus, it should be anteverted. That massage can be given on a retroverted or retroflexed uterus, where adhesions prevent its reposition, is understood; but the anteverted position is preferable, and reposition should always be made first when the uterus is movable; the only exception is if the position should cause irritatian of the bladder when it is kept retroverted.

5. Cervical catarrh and enlargement, in which the massage is made downward toward the isthmus.

6. Massage is also often given before and after reposition in displacements on one or more of the uterine ligaments.

7. Chronic oöphoritis or peri-oöphoritis, when the ovary, as well as the surrounding parts, especially upward and backward, are masséed.

A differential diagnosis can often be made between oöphoritis and peri-oöphoritis through the result of the treatment; in the latter, where the enlargement of the ovary is due to swelling of the surrounding tissues, it is especially amenable to treatment; the former is not so much so.

The contra-indications for the stronger massage are:

1. The acute inflammatory character of the disease.

2. Menorrhagia and metrorrhagia.

3. Amenorrhœa; massage on the corpus is contra-indicated in these cases.

The larger and often quite powerful kneadings with the whole hand, roll frictions or kneadings with the palm of the hand through the abdominal wall, are used on a very enlarged uterus or on very large and hard exudate where all inflammation has disappeared.

The manipulation which Brandt—for lack of a better word to describe it—calls "paintings" (German, "malen") is a kind of curved-shaped stroking, produced by the forefinger in the rectum, along the pelvic wall in direction from downward upward, or from forward backward, according to the direction of lymph-vessels and veins. It is indicated in inflammatory conditions (not too acute) or exudations in the uterus or ligamenta lata.

Stretching is produced either by trying bimanually to seize the contracted or adherent part and gently stretch it; or bimanually by taking hold of the adherent uterus or ovary and trying to free it; or by passing the finger up into the rectum, behind or above the adhesions, and gently and continuously press the uterus, first on one, then on the other side of the contracted and adherent part. This can be done with the patient standing, lying, or in the knee-chest position, always remembering to observe the patient so as not to do too much at one time.

The indications for the stretchings are:

1. Peritoneal adhesions, principally between the uterus or the ovaries and other parts of the pelvis.

2. Scar-retractions in the pelvic connective-tissue.

Contra-indication to stretchings in inflammatory conditions of the parts.

Repositions are produced in different ways, according to the deviations of the organ, and it would take too long a time to enter into a description of its different modifications. They are indicated in:

1. Deviations of the uterus, when it produces discomfort or sterility.

2. To improve the position of the uterus for a more effective massage.

Contra-indications: Firm and sensitive adhesions or retractions.

Uterine lifting is indicated in:

1. Prolapsus uteri (of all degrees).

2. Prolapsus vaginæ, with cystocele and rectocele.

3. Retroversion and flexion.

4. Anteversion (with some modification adapted to the case).

5. Latero-version (with some modification adapted to the case).

The contra-indications are:

1. Para- and perimetritis.

2. Oöphoritis.

3. Menorrhagia.

The modus operandi, which is hard to describe, is the following:

If there is prolapsus the uterus is restored to position in the usual way, and when that is done the so called "double-treatment," or the lifting, begins. The uterus is supported in the vagina by the forefinger of the physician placed on the vaginal portion. A woman assistant then kneels down on the couch between the knees of the patient, places both of her hands flat on the abdomen, their ulnar sides touching each other; the physician first placing his free hand on the abdomen, and pushing the integument from above downward, to guide the assistant and give her a kind of grip, so to speak, of the uterus; then she presses her finger-tips

down in the pelvis, in front and to the sides of the uterus, slightly flexes the fingers, grasps the uterus and lifts it and its adnexa upward, and lastly, somewhat forward, following the axis of the pelvis. The physician with his finger on the vaginal portion, follows the movement of it during the lifting as far as it is possible to reach, and presses it backward. These "liftings" are repeated three times, after which Brandt gives some light massage, as said before, by which he tries to stimulate the hypogastric plexus and the posterior portion of the sacro-uterine ligaments of both sides.

These liftings are modified according to the individual case and its need; and the "liftings" are never given when the uterus is retroflexed or retroverted.

If cystocele is present he gives a vibratory stroking pressure on the relaxed protruding part, the strokings being made upward and inward by the tip of the index finger, avoiding the urethra.

When this procedure is completed the patient lifts her buttocks and the lower part of her back from the couch, supporting herself with her neck and upper part of her back, as well as by the feet resting on the couch and with closed knees. The physician then separates her knees while she resists, and she closes them while he resists.

The purpose of these exercises is to strengthen the pelvic floor, especially the levator ani.

The patient is then given light tapotement over the sacrum.

How this method produces cure in displacement and prolapsus has been discussed a number of times, and many theories and explanations have been given. Dr. Boldt says that Schultze considers the cause to be contraction of the sacro-uterine ligaments. Whatever the cause may be, the cure remains a fact.

The exercises given to the abductors of the thighs are an important factor in producing the desired results.

In the summer of 1882 I saw the first complete prolapsus uteri cured. The woman came to Brandt the 29th of June; the 11th of July the uterus was retained within the body, although the anterior wall of the vagina protruded on exertion; the 9th of September she was well, with the uterus in normal position.

That this treatment of prolapsus exerts a powerful curative influence every one who has followed it, or tried it, must fully recognize.

As said before, movements are given to every patient to improve her general health.

I sincerely hope by this paper to call the attention of the profession to this valuable therapeutic means, so well known in this country, and always looked upon with prejudice and suspicion, which it deserves as little as any other treatment, when undertaken by skillful operators. The investigations concerning and acceptance of it by a man of such standing in the scientific world as Professor B. S. Schultze ought to be an unquestionable and sufficient guarantee of its efficiency.

However many theories there may be, however many objections there may be raised, the efficacy of the treatment in indicated cases remains a fact, which neither objections or theories have the power to overthrow, and this fact I have been able to observe for a long time. In certain cases especially adapted for this treatment I have seen no other which can compare with it. Larger experience and further investigations will show the truth of this, as well as give more definite conclusions as to its indications and contra-indications.

And, lastly, I will quote the following words from Dr. Levertin, which I think are fitting in this case also: "I ardently wish that nobody may see, in these descriptions, the expression of excessive enthusiasm only, but rather the conviction of an unprejudiced critic desiring to make profelytes to his doctrine confirmed by experience among more or less skeptical colleagues."

## CONDITIONS JUSTIFYING REMOVAL OF THE TESTICLE IN RADICAL OPERATIONS FOR INGUINAL HERNIA; WITH A REPORT OF THREE SUCCESSFUL CASES*

THOMAS S. K. MORTON, M. D.,† PHILADELPHIA, PA.

FELLOWS OF THE ACADEMY OF SURGERY: Prior to making my remarks upon the above subject I desire emphatically to press the fact that I am not here to advocate the indiscriminate sacrifice of an organ usually so highly prized as the testicle, but simply to point out certain of the conditions which would appear to me to justify the procedure and to relate three cases in which I have considered it best to resort to it. These cases represent the total number in which I have deemed it prudent to add ablation of the gland to formal procedures for the radical cure of inguinal hernia, for instances are rare in which this course may be considered justifiable, and must become constantly more and more so as radical procedures become perfected.

With the operations proposed by Bassini, Postempski, and Halsted, with their modifications, where the cord is displaced entirely from the inguinal canal, and, in the latter, even removed from the internal ring to an entirely new opening made for the purpose in the muscular structures of the abdominal wall; with these operations, I say, the presence of the cord has almost ceased to be a hindrance to seemingly ideal radical cure. Hence any temptation to sacrifice the testicle vanishes, and the conditions necessitating or permitting such removal become correspondingly more circumscribed.

Removal of the testicle in operations for inguinal hernia would, therefore, in my estimation, be practically limited to the following conditions:

1. Certain cases of undescended testicle.

Here, if the testicle had entered the canal and was degenerated or otherwise diseased, or could not be separated from the sac without endangering its vitality, or where it was manifestly functionless, it might be removed without reluctance. But if it were normal, or almost normal in all respects save position, it would be best, if possible, to displace the cord from the canal by one of the modern methods and attempt to bring the organ into the scrotum and there fix it by sutures; or it might be pushed within the abdominal cavity through the internal ring, and there permitted to remain after close suture of the ring.

2. In some rare cases of congenital hernia.

Removal here must be very exceptionally called for with so many modern operative resources at hand.

3. In certain cases of chronic or acute disease of the testicle or cord complicating hernia demanding removal of the organ upon its own account.

4. In rare cases in which severe traumatism has occurred to testicle or cord during or before operation.

Accidental division of some or all of the vessels of the cord would not necessarily demand excision of the testicles unless other severe complications were present. Wounding or section of the vas deferens likewise might be consistent with retention of the organ. But where the gland has been stripped entirely from all other connections such injury to its vascular supply would produce so much danger of necrosis that ablation would become imperative.

5. In certain cases where sloughing of the sac or interrupted circulation of the cord or testicle has involved these latter structures in a suppurative or sloughing process.

6. Perhaps occasionally in the very aged, to simplify or shorten operation, or for some of the before-mentioned conditions of less degree than would justify the procedure in a younger individual.

There are no conditions of course, except senility, that would excuse the removal of a testicle under circumstances

*Read before the Philadelphia Academy of Surgery, March 5, 1894.

†Professor of Surgery in the Philadelphia Polyclinic; Out-Patient Surgeon to the Pennsylvania Hospital; Assistant Surgeon to the Orthopedic Hospital, etc.

where it was the sole reproductive gland possessed by the individual; even more rare would be the conditions justifying removal of both testicles in double herniæ.

Surgeons must be exceedingly cautious not to interfere with so highly-valued a part without either a very clear understanding with the patient before witnesses (and preferably in writing) preliminary to the operation, or else be certain that the conditions for which the organ is removed will be convincing to others of the necessity for such removal. It is obviously important also for the operator to carefully preserve the specimens for his protection in case of dispute.

One word more of caution. It is not the easiest matter to tie off the testicular cord in such a manner as to leave it absolutely secure against recurring or secondary hemorrhage after its return to the abdominal cavity; and bleeding from it originates a peculiarly dangerous form of shock quite independent of the amount of blood lost, which often is speedily fatal. Moreover, the bleeding will not be likely to cease spontaneously in the warm and most peritoneal cavity to which the ligated stump has been returned, and operation to secure it more firmly (if diagnosis is made in time) would be a very formidable complication. Hence, excessive care must be exercised in its primary ligation. It should be transfixed and tied off in at least two portions. Silk is the only fit material for this purpose. A good button of tissue should be left above the ligatures, and, to be doubly sure, any apparent vessel ends should be separately ligated upon the end of the stump before it is returned to the cavity. Searing the stump with a cautery below the main ligatures would be equally, perhaps more efficient than the separate ligatures to the vessel ends. If the cord were very large or œdematous it should be ligated in even smaller portions.

Case I. *Huge Strangulated Inguinal Hernia; Radical Operation with Removal of the Testicle; Recovery.*—Mr. M. C. B., a strong, healthy man of nearly fifty-seven years, strained himself fourteen years ago whilst pulling a heavy satchel across the floor. It caught on a splinter, and, as a result of straining to dislodge it while in a stooping position, he felt something give way in the left groin, and became exceedingly faint. Shortly after this a small, reducible, but constantly reappearing tumor, came into the scrotum, and, as time went by, became gradually larger and larger.

Several years after the first appearance of the tumor, and when it had attained quite a large size, he became subject to occasional attacks of strangulation, which always required anæsthesia for reduction. Then, after one of these attacks, a large portion of the tumor became irreducible, and so remained. After this when the seizures came on strangulation could always be overcome by reduction of a portion of the hernial contents, but the entire tumor could never be reduced. Several more attacks of strangulation occurred at varying times after this, when more intestine would become prolapsed, but relief was invariably obtained upon reduction of the newly prolapsed and strangulated portion. While strangulation lasted his chief symptoms was always an agonizing dragging pain at the epigastrium. By wearing a truss over the site of the external abdominal ring, that portion of gut which prolapsed and produced strangulation was more or less effectually kept up.

About 8 o'clock P. M., April 10, 1889, he felt the hernia slip out, and became a little faint and sick; but after lying down for a short time continued at his desk until midnight. At 1 o'clock A. M. he reached his home in West Philadelphia by street car and foot from the city. His sensations were then different from anything that he experienced before, and he was certain that he was about to die—on similar occasions he had always been most confident and hopeful. At 3 o'clock A. M. he was seen by the late Dr. Michael Lampen, who always heretofore had been able to reduce the strangulation by taxis. The doctor, therefore, promptly placed the patient under anæsthesia, but was unable to reduce the tumor after an hour's application of taxis. He, however, could not let up the ether on account of the man's terrific sufferings. Ether narcosis, with an occasional application of taxis, had been kept up continuously from 3 A. M. until 8 A. M., when I saw the case in consultation. The patient's condition at the latter time was fairly good, but he was much depressed by the prolonged anæsthesia. No fecal vomiting had occurred.

Upon examination an enormous left-sided inguino-scrotal hernia was discovered.

It was fully as large as a man's head; the skin covering it was exceedingly tense, shiny, and almost black from inguino-scrotal impeded circulation. Fluctuation was marked over the upper and outer portions of the tumor, whilst at that portion near the man's knees was present a large semiglobular boggy mass just beneath the skin.

Consent to operation having been obtained from the wife, taxis of a moment's duration was unsuccessfully employed, and operation at once proceeded with. Full aseptic measures prevailed throughout. A six-inch incision was made in the line of the tumor and inguinal canal, and carried down to the sac, which was punctured and torn to an equal extent. About a pint of brownish-tinged odorless serum escaped from the opening, and the small intestine at once came into view. This was highly distended with flatus, almost black, and in places ecchymotic. The constriction was then sought for and found to be at the external ring. This was incised upward, and the three feet of prolapsed small intestine was—after it had begun to assume a pinkish color—with some difficulty returned to the abdominal cavity, a healthy portion having first been pulled down at each extremity to make sure that no constricion existed at a higher or lower point. Attention was now turned to the remaining prolapsed mass. This had the appearance of being an enormously hypertrophied omentum, and was not in the slightest degree congested or strangulated. At first sight I took the mass for omentum; so great was its resemblance thereto, and it was only upon most careful examination that its true nature was revealed. It proved to be practically the entire colon, excepting possibly the cæcum, which could not be recognized in the confused mass, as well as the omentum attached. This discovery was made by finding deep, between two layers of fat, a band of fibrous material through which muscular fibres coursed, and, later, by feeling a small fecal mass in the lumen. The bowel was absolutely collapsed, practically free from feces, and deeply buried in hypertrophied surroundings. The mesocolon also participated in these changes, and was likewise rendered almost indistinguishable by fat deposit. Only a longitudinal half-inch strip of bowel could anywhere be brought to sight. The epiploic appendages were enormous. (An illustration that it should be an invariable rule to cut or ligate nothing about a hernia until absolutely sure of its nature.) The mass was separated from its many adhesions to the sac, but, from its great size, after separation could not be reduced through the abdominal rings, although these were very much dilated. Hence the incision was enlarged upward along the inguinal canal and the internal ring very freely divided upward upon the abdomen for a distance of several inches. The colon and omentum were then easily reduced, and attention turned to the sac. This was found universally adherent and particularly to the peri-testicular tissues. Its dissection was finally accomplished up to and within the internal ring, where it was cut off and the ends sutured together. I did not employ the method of dealing with the sac in this case that is advised by Macewen, because of the very large mass of perhaps devitalized tissue which would by that method have been returned to the abdomen. Where the sac is not very large, however, that procedure is quite a favorite with me.

The left testicle was elongated, hypertrophied, and so enveloped by the sac as to give it much resemblence to a prolapsed kidney, but examination quickly demonstrated its identity. After the sac had been dissected up it was found that the testicle was left without any vascular attachment excepting through the cord. Then arose the question whether it should be allowed to remain. This, again with the consent of the wife, was decided in the negative for the following reasons: the organ was much hypertrophied and œdematous, and likely would require more blood than could be conveyed to it by the perhaps bruised and occluded cord; the patient was fifty-six years of age; the opposite testicle was apparently quite healthy and normal; and, finally, a much more certainly radical operation could be done by having the cord out of the wound. Again, had the organ been allowed to remain its life was by no means certain, and its necrosis might have made a very dangerous complication during convalescence. Hence the cord was ligated just below the internal ring and the testicle cut away. After being very certain that every vessel of the cord was firmly occluded by the ligatures, the pedicle was dropped within the abdomen. A glass drain-tube was placed

in the extreme upper portion of the abdominal wound. Then a layer of deep sutures of chromic catgut were run along the muscular structure of the wound down to the internal ring, through that structure and down along the canal to and embracing the external ring, thus giving a secure and accurate opposition of all the parts concerned in the hernial opening unimpeded by the presence of the cord. Were I doing this same operation to-day I would probably not introduce the tube at all, but if it were called for, would insert it through a separate median opening just above the pubis. However, in this case no harm resulted from leaving the upper portion of the wound weakened by a drain-tube orifice. The entire skin wound was next approximated by interrupted silk sutures a double-spica bandage applied over a copious dressing.

As soon as consciousness returned he was put upon powders of calomel one-tenth grain, and podophyllin one-sixth grain every hour. These he took for twelve hours, and then was placed upon one-drachm doses of Epsom salts hourly. No food was permitted for twelve hours. Bowels moved very freely next morning with the assistance of an enema. From the time of coming out of the ether until the day following he was violently restless, pitching and tossing about the bed in an altogether uncontrollable manner. Somehow in the night he had, without the knowledge of those about him, managed to withdraw the drain-tube. This I found lying loose in the bed when I saw him early next day. The bowels by that time having freely moved and the belly being entirely flat, I determined not to replace the tube unless compelled to do so. Jactitation controlled by fifteen grain-doses of chloral.

April 15th. Belly slightly distended. Still somewhat restless; for this more chloral. Bowels have again moved very freely. Temperature has not been above normal. Violent bronchitis present as result of the prolonged anæsthesia.

16th. Abdomen much swollen, nausea and non-fecal vomiting; complains much of pain; racking hiccough present; bowels not moved to-day. Decided to reinsert tube. Removed stitch at extreme upper portion of the wound and put glass drain-tube down to hollow of sacrum, and through it drew off two ounces of turbulent, bloody, non-odorous serum. Wound in excellent condition. Again put bim on fractional doses of calomel and podophyllin. Bronchitis improving, but much purulent expectoration continues.

17th. Bowels freely open. Small amount of serous straw-colored fluid from tube. Hiccough and vomiting continue obstinately. For latter symptoms ordered cocain one tenth grain, oxalate of cerium two grains, and bicarbonate of sodium two grains, every two hours.

18. Vomiting and hiccough entirely under control. Bowels moved of their own accord, abdomen entirely flat and painless. Discharge had ceased, so tube was removed, as well as all the skin sutures. Patient eating and sleeping well. Bronchitis almost gone.

On May 4th he sat up and began to get about; in two weeks more was at his business again.

When seen about a year after the operation there was present a firm cicatrix and no sign of return of the hernia. Up to the last time that I heard from him, several years afterward, he continued entirely free from the return of the hernia. *Transactions of the Philadelphia County Medical Society*, 1889, p. 206.)

CASE II. *Large Strangulated Inguinal Hernia; Sloughing Intestine; Radicul Operation, with Removal of Testicle; Recovery.*—Jacob B., aged forty-three years, was brought to me by his physician, Dr. James Robinson, on March 6, 1893, and admitted to the Polyclinic Hospital. He stated that he had had a large tumor in the left scrotum from childhood, and could not remember when it had originated. By manipulation at times he thought that it had become somewhat smaller. It never had given him any annoyance.

On March 1st, while in apparently perfect health, he drank a quantity of ice-water, which induced vomiting, during which he felt a "giving away" sensation in the left inguinal region. From this time he continued to vomit everything taken and to experience extreme nausea. Bowels also ceased to move. The tumor became more and more painful and swollen. He continued in this condition five days, and then summoned Dr. Robinson, who applied taxis for thirty minutes without making any impression on the mass. On the sixth day he walked a number of squares to the hospital.

Upon admission I found a tumor the size of a large cocoanut occupying the left scrotum and inguinal canal. The testicle was below the general mass and could be outlined as distinct from it. The whole tumor was very tender and somewhat œdematous. Deep-fluctuation was marked. No percussion resonance, or succussion. A very resisting mass occupied the inguinal canal. Bowels has not moved for six days. Constant fecal vomiting. Condition very fair.

A diagnosis of chronic hernia of the ementum, with acute entanglement of a portion of the intestine, together with hydrocle of the hernial sac, was made, and immediate operation insisted upon.

After preliminary cleansing and anæsthsia, without waiting to make prolonged taxis, which was clearly prohibited by the long duration of the strangulation (as the subsequent history clearly demonstrated), a five-inch incision was made in the line of the inguinal canal and scrotum. The cellular tissues were œdematous and had some odor of decomposition. The sac was exceedingly thick and highly discolored, as if about to break down. It was freely incised, and half a pint of dark, turbid fluid of putrefactive odor escaped. The sac contained a large mass of hyperrophied omentum of the character so frequently found in omental hernias; it was adherent by firmly organized attachments to most of the sac-wall. It was purple in color, intensely congested, and very œdematous. The whole was stripped from its adhesions and carefully spread out, whereupon a portion of small intestine came into view that had been entirely wrapped up in the folds of the omentum. This again illustrates the extreme care that is always so necessary in handling the contents of a rupture; for it would have been exceedingly easy to have ligated off the omentum and bowel together in this case, and to have returned the stump to the abdomen, thus insuring a fatal issue. A finger passed into the inguinal canal discovered a very tight constriction at the internal ring, which was freely divided upward. The omentum could now be pulled down with ease until entirely healthy portions appeared, where it was ligated off in two bundles by transfixion, and the stump returned to the cavity and fixed immediately behind the internal ring by bringing both of the ligature ends through different portions of the muscular wall and then tying them down as suggested by Macewen for making a protecting pad of the sac in his radical operation. The prolapsed intestine could now be freely inspected.

Upon the free margin was a gangrenous spot one-half inch in diameter, which appeared to be in imminent danger of rupture. The remaining portions of intestine were almost black from venous stasis, but were not actually sloughing. The sloughing portion was buried under healthy peritoneum by means of Lembert sutures; buckled into the lumen of the bowel, as it were, just as if perforation had taken place. Fortunately this procedure did not too much diminish the lumen of the bowel; and by the time that it was completed all excepting the sloughing portions of the intestine had, under hot irrigation, resumed the beautiful pink tint of returning circulation. The bowel was then returned to the abdominal cavity.

After a very difficult dissection the sac was freed of its attachments to the scrotal, testicular, and cordal tissues, and ligated off in two sections at the internal ring. The stump of omentum was next fixed behind the ring as described. Attention was now turned to the testicle and cord. These structures were œdematous, had the general foul odor of all the surroundings, and, in spite of careful separation, had been considerably injured by the dissection and other manipulations. It was considered that leaving such structures in a wound already gravely threatened with suppuration, if not sloughing, was an unjustifiable risk to which to subject the patient, as the testicle, under these circumstances, was likely to break down and slough with accompanying dissecting suppuration, and especially was it desirable to secure for this hard-working man a radical cure if possible. Hence the cord was ligated at the internal ring most carefully by a transfixing double ligature of silk and also returned to the abdomen. This permitted a careful and complete closure of the internal ring and the whole inguinal canal by buried silkworm-gut sutures placed about three-eighths of an inch apart. A small rubber drain was placed in the lower portion of the scrotal wound, but none in the upper portion and the skin margins approximated by silk sutures.

Excepting a small amount of suppuration in the scrotum, the entire wound

healed by primary intent. The drain was removed on the third day. The bowels moved within twenty-four hours spontaneously, and naturally each day thereafter. There were some small clots of blood in the first stool, but none subsequently. He was given absolutely nothing by mouth for thirty hours subsequent to the operation; but rectal enemata of warm water were frequently administered, which prevented thirst. Then liquid diet was started and full diet gradually resumed. He was kept in bed three weeks, and resumed his duties as a hotel waiter in five weeks. He was instructed not to wear a truss.

I last saw this man on November 2, 1893. There was no sign of return of the hernia. The cicatrix was sound. He has been working hard at his occupation ever since the operation, has not worn a support, and expressed himself as stronger and better in every way than he had been for years.

CASE. III. *Strangulated Congenital Inguinal Hernia; Radical Operation with Removal of Undescended Testicle; Recovery.*—Irvin B., aged nineteen years, was admitted to the Polyclinic Hospital, May 9, 1893. He has enjoyed excellent health all his life, but always has had a "come-and-go" tumor in the right scrotum, and has never been able to distinguish a testicle upon that side. The opposite testicle is large and firm. The tumor could always be reduced with ease, and likewise disappeared whenever he laid down. It was painless. He had never worn a truss.

On the morning of May 8th, upon slight straining while at his work of tile-setting, he felt a painful and unusual sensation in the right side of the scrotum, and went home, nauseated and in great suffering. He then discovered that a tumor much larger than usual was present, and that it was tender and irreducible. The bowels moved a few hours subsequently.

On May 9th he applied to me for relief, and I insisted upon his entering a hopital. No movement of bowels except shortly after strangulation. Much nausea and anorexia, but no actual vomiting had taken place. Belly somewhat distended, but general condition good. In the right inguinal region was a tumor of considerable proportions and very sensitive. Fluctuation was very marked in the dependent portion of the scrotum. No succussion; no percussion resonance. Inguinal canal tense and occupied by a solid mass. Testicle could not be defined.

The man was given a bath upon admission, and, consent to removal of the undescended testicle having been secured, immediately etherized. Taxis was then made for five minutes, and failed. Immediately upon failure of taxis a long incision was made over the inguinal canal and tumor and carried down through the tissues until a thin-walled sac was freely exposed. This was also incised, and four ounces of brownish serum escaped, disclosing a web of congested omentum and about four inches of small intestine. The omentum was inky black, the intestine not quite so much injected. A very small and tight constriction was found at the internal ring. This was divided by a Cooper hernia knife with considerable difficulty, incident to the high location of the ring and to the intense constriction—bowel as well as sac overlapping on all sides. A small rent in the serous covering of the bowel resulted, but was immediately repaired with a half dozen Lembert sutures. I have since learned to cut the ring from above in all difficult cases, and thus to avoid the risks of wounding the bowel or other structures passing through the ring. As a division of the ring and roof of the canal from above is now an established procedure when making radical cures for hernia in this situation, division of the ring from below may go entirely out of fashion excepting in desperate cases or in those of the very aged or feeble, where radical operations must be ruled out owing to the increased danger to life inseparable from prolonged operative manipulations.

So soon as the constriction was relieved the bowel and omentum at once resumed their normal color and circulation. The omentum was ligated off in portions and the stump returned to the abdominal cavity. More intestine was then pulled down, as usual, but no further constriction found, and it was also returned to the cavity.

In the sac wall at the position of the external abdominal ring was found undeveloped undescended testicle about half an inch long and three-eighths of an inch wide. This was dissected out with a portion of the sac, the pedicle securely ligated, the testicle cut away, and the stump

returned to the peritoneal cavity. It could have been reduced with the sac, but could not have been returned to the scrotum with a cord manufactured out of a portion of the sac-wall including the testicular vessels and vas deferens. When I considered the uselessness of the organ in its undeveloped condition, its well-known propensity to degenerations and other diseased conditions, and, moreover, as I had secured his consent to its removal, and could make so much better a radical operation with no structure traversing the rings or inguinal canal, it appeared more than justifiable to sacrifice the organ, especially as its fellow was in a perfect condition. The sac (containing the pedicle of the cord) was next dissected free from its surroundings up to and a little within the internal ring. Here it was puckered up after the method of Macewen with a thread and needle and fixed just behind the internal ring, to act as a pad to protect that region from the possible return of a portion of gut. The internal ring and inguinal canal were then completely obliterated by silk sutures and the skin likewise, sutured by silkworm-gut. No drainage was employed. His bowels were moved by fractional doses of calomel and podophyllin within twenty-four hours, and in three days he was eating semi solid diet. The wound healed throughout by primary union. He was kept upon his back for three weeks and resumed his occupation in five weeks. No truss was prescribed.

I have seen this patient recently,—almost one year since the operation—and found the cicatrix sound, with no sign of return of hernia.

## AN OBSERVATION OF THE EFFECTS OF ERYSIPELAS ON EPITHELIAL CANCER.*

JAMES COLLINS, M. D., PHILADELPHIA.

About eighteen months ago my attention was called by Mr. M. to on ulcer nearly opposite the ear, on his right cheek. This ulcer was one and a half inches in longest diameter, one inch in the shorter, presenting an oval with irregular edges. The discharge was slightly purulent, tinged with blood. The granulations were soft and bled on the slightest touch.

Mr. M. stated that twenty years ago there appeared at this point a small elevation, which frequently formed a scab, which every ten or twelve days would fall off and then re-form, giving but little trouble received but little treatment.

Nineteen years ago he was treated for a time with ointments and lotions, also some medicine was administered without special benefit. He was then assured that this was skin cancer and incurable. This ulcer gradually increased in size and depth. Some benefit was derived from a lotion of zinc sulphate and salt, dissolved in water to make a mild astringent solution. The ulceration, however, continued giving inconsiderable pain, but much annoyance by it presence. The good man quietly accepted the situation, seeking only palliation and relief from pain.

About November 12th he suffered from an attack of erysipelas of the face. This ran no unusual course, spreading rapidly from tip of nose over scalp to nape of neck. The efflorescence was followed by desquamation. The external dressing was of ichthyol and lanolin, which seemed to give relief and comfort.

As the erysipelas fadded out, the desquamation following the ulcer seemed to assume a more healthy appearance. Granulations of a more normal character developed and in about two weeks the ulcer was entirely healed. The cicatrix on March 1st is slightly indurated, but smooth and firm, presenting the appearance of normal cicatrical tissue.

This case is reported without special comment. Dr. Coley, of New York, has written on this subject with considerable interest.

The writer is well aware that a single case from the practice of a surgeon is but of little value, isolated and alone, but hoping that others may add their experience and observation the case is reported for consideration.

* Read before Philadelphia Academy of Surgery, March 5, 1894.

# VERBAL REPORT OF THREE CASES OF LEFT INGUINAL COLOTOMY.*

JOHN H. PACKARD, M. D., PHILA.

By some surgical writers, notably the elder Gross, the opinion had been expressed that the making of an artificial anus by opening the colon placed the patient in a condition so distressing that death itself would be preferable. My own experience with these operations warrants me in upholding a very different view. My first case occurred in 1873, and I had the advantage of the presence and assistance of Prof. Gross and of Dr. Levis; the patient, whose rectum was occluded by a uterine cancer, lived in comfort for eight months, dying then from exhaustion due to the advance of the disease. In this instance, and in other cases for many years afterward, I made the opening in the left loin, thinking the access more ready, and preferring to avoid encroaching upon the peritoneum. There is, however, one great objection to the method, that the point of exit for the feces is so placed as to be only with difficulty reached by the patient, and to require the assistance of others in attending to it.

For the operation in the left groin, I think the best rule as to the incision is to make it just as on the right side in appendicitis, an inch and a half from the left anterior superior iliac spine, and at right angles with a line between this process and the umbilicus. With scrupulous asepsis the opening of the peritoneum is made with safety; the operation is one of no more difficulty than that in the loin, and the artificial anus is entirely under the patient's control. The directions given in some of the books for the finding of the bowel seem to me to be needlessly complex; if the large intestine does not immediately present itself in the wound, a portion of the small intestine will, and must be pushed aside, when the sigmoid flexure, especially if distended, will be seen, and may be recognized by the longitudinal muscular bands.

My own opinion is that it is a matter of but little moment whether the bowel is opened at once or after the lapse of several days.

I do think it important that the gut should be well drawn down into the wound until the portion above this point is slightly tense, so as to avoid subsequent prolapse through the artificial anus. Even with this precaution it sometimes happens that the inner wall will pouch out and be a cause of some annoyance.

For suturing the edges of the peritoneum to those of the skin it is well to use black silk, so that these stitches may be readily distinguished from those by which the bowel itself is fastened in the wound; these latter should be of white silk, and should penetrate beyond the muscular coat, but not through the mucous membrane.

It is not always easy to judge how large an opening should be made into the bowel. In a child, or when the wall of the gut is very thin, a small orifice will suffice; and I do not think more than three-quarters of an inch is ever necessary.

CASE I.—James Brewster, a mulatto, aged fifty-five years, but looking much older, was admitted into my ward at the Pennsylvania Hospital, November 26, 1892, on account of epithelial cancer of the rectum. His condition was most deplorable; there was a mass of disease stiffening the wall of the bowel and discharging from its ulcerated surface a very offensive pus, which, mixed with fecal matter, flowed away constantly through the wide-open anal orifice. Hence he not only suffered agonizing pain, but the intolerable fetor made him loathsome to himself as to all about him.

He had, moreover, a left inguinal hernia, which he ascribed to the kick of a horse in January, 1891. This did not in any way interefere with the operation, which was done four days after his admission. The opening into the bowel was not made until December 4th, or four days later.

Immediately after the operation his temperature fell to 97.6°, but he soon rallied and did well. The artificial anus gave no trouble, but was cleansed once daily. By means of washing out with solution of potassium permanganate or other detergents, the rectum was rendered inoffensive. A portion of the diseased

*Read before Philadelphia Academy of Surgery, March 5, 1894.

mass was curetted away about four weeks after the colotomy, but no more radical procedure seemed to be justified.

The patient lived in comfort until April 18th, nearly five months, and then died painlessly from exhaustion.

At the autopsy it was found that the morbid growth extended five inches above the anus, and had involved the posterior wall of the bladder; there were abundant deposits in the pelvic and mesenteric glands.

A somewhat noticeable fact was that the serous covering of the gut was adherent to the parietal peritoneum for a long distance above the point of operation.

CASE II.—Ellen Black, aged fifty-two years, was admitted under my care in the Pennsylvania Hospital, October 24, 1893, suffering from extenisve cancerous disease of the uterus, involving the rectum; she had not had a natural stool for a year. Her general health was not greatly impaired, but she had great distress by reason of the rectal obstruction.

The next day I exposed and secured the sigmoid flexure, and twenty-four hours afterward opened the bowel. Just after the operation her temperature feel to 96. 2°, but reaction took place quickly. Regular movements were soon had through the artificial anus, and on the seventeenth day she was discharged at her own request, to return to her home in Sullivan Co., Pa.

CASE III.—Mrs. M., aged about fifty, living in one of the cities in the interior of this State, was seen by me in April, 1893, on account of almost total obstruction of the rectum by the pressure of a tumor of the womb, which filled up the entire pelvic cavity. To attack this in its then condition seemed to me, as well as to her physicians, unwarrantable; and as her suffering arose mainly from the rectal obstruction, I proposed opening the bowel in the left groin. To this she agreed, and I performed the operation at her residence. Complete relief was afforded, and after some experiments in the devising of a suitable contrivance for keeping control of the contents of the bowel, this lady was enabled to resume her active life, going into society freely, and attending to all her affairs without hindrance.

Should this tumor, probably a fibroid, develop so as to rise out of the pelvis, the question of hysterectomy might be entertained; and if this were successfully accomplished the closure of the artificial anus might, perhaps, be undertaken.

# TRANSLATIONS.

## THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

### THERAPEUTIC ACTION OF ALPHA-NAPHTHOL.

Dr. Maximovicz (*Wiener Med. Presse*, No. 10, 1894) has studied the physiological and therapeutic action of alpha-naphthol and finds that it is three times as powerful a bactericide and far less toxic than the beta-naphthol. In typhoid fever he usually administers it in doses of 0.50–1.0, three to four times a day; if this be insufficient he increases it to 6–8 gms. Under the influence of the drug the morning remissions are less pronounced, the tongue clears up, the meteorism and the pains in the right iliac fossa decrease and finally disappear. The duration of the disease is markedly shortened. It must be continued until the temperature has remained normal for three to four days. The formulæ are as follows:

℞

| | | | |
|---|---|---|---|
| Alpha-Naphthol | .050—0 | 75 | (grs. —viij-xij). |
| Bismuth Salicylate | 0 | 30 | ( " v). |
| Powd. Cinnamon | 0 | 20 | ( " ij). |

For one powder. Make twenty such. Four to six powders, per diem.

If there be great meteorism with violent abdominal pains than use:

℞

| | | | |
|---|---|---|---|
| Alpha-Naphthol | 0 | 50 | (grs. viij). |
| Bismuth Salicylate | 0 | 30 | ( " v). |
| Powdered Rhubarb | 0 | 20 | ( " ij). |
| Extr. Belladonna | 0 | 01 | ( " 1-6). |

For one powder. Make twenty such. Four to six powders a day.

Or,

℞

| | | | |
|---|---|---|---|
| Alpha-Naphthol | 0 | 50 | (grs. viij). |
| Codeine | 0 | 01 | (gr. 1-6). |
| Powdered Rhubarb | 0 | 10 | (grs. jss). |
| Powdered Cinnamon | 0 | 20 | ( " ij). |

For one powder. Make twenty such. Four to six powders a day.

*In charge of the Translator, F. H. Pritchard, A. M., M. D.

In dysentery he has had very good results with alpha-naphthol and castor oil:

℞ Alpha-Naphthol 1.0 | 4.0 (grs. xv-℥j).
Castor Oil..... 100 | (℥iijss).

From a coffee to a tablespoonful several times a day.

In the grippe he employs the following combination:

℞ Alpha-Naphthol.....0 | 50 (grs. viij).
Calcined magnesia.....0 | 20 (grs. ij).
Phenacetine.....0 | 30 (grs. v.)

For one powder. Make twenty such. Four to six a day.

In pulmonary tuberculosis with disturbance of the intestinal functions and profuse night sweats he prescribes, with good results, the following pill:

℞ Beechwood Creasote.
Alpha-Naphthol,..... āā·8 | 0 (℥ij).
Arsenious Acid.....0 | 12(.grs. ij).
Strychnine Nitrate,..... 0 | 05 (grs. ¾).
Atropine Sulphate ..... 0 | 01 (grs. 1-6).
Extr. Gentian.
Gum Arabic. āā. ad 120 pills.

Four to six pills a day.

In erysipelas, small-pox and other skin diseases he has employed a solution of the drug in olive oil, with good effect:

℞ Alpha-Naphthol,..... 0 | 10-30 (grs. jss-v).
Olive Oil.....100 | (℥iijss).

For external use.

---

### COTTON-ROOT AS A HEMOSTATIC IN MENORRHAGIA.

Dr. Poteyenko (*Revista De Ciencias Medicas de Barcelona*, No. 4, 1894) having his attention called to the value of the extract of cotton-root as a hemostatic, in a case of uterine hemorrhage, has employed it as a hemostatic in various forms of hemorrhage. In all he had prescribed it in fifty-nine cases, administering the extract in doses of twenty to thirty drops, three to four times a day; the curative effects are generally noticeable on the first or second day of its administration, even when other hemostatics have been used in vain. The most notable case was that of a man of twenty-five years, who, in good health and well nourished, had suffered from daily attacks of epistaxis for over three months, for which he had consulted several physicians. On examination of the nose only a hyperemic state of the mucous membrane was to be observed. Ergotine, Hydrastis Canadensis, Fowler's solution and locally, solutions of tannin, boric acid, etc., were prescribed. No result being obtained he administered the fluid extract of cotton root, Gossypium herbaceum, twenty-five drops three times a day. The patient did not return and when accidentally met a week later, he said that after taking the remedy for three days the epistaxis did not reappear. For a whole year since he has been free from the hemorrhages. From his cases and observations he concludes that cotton-root is an efficacious, inoffensive and quite certain hemostatic, which not only does not disturb, but on the contrary, assists digestion. It may be employed in the treatment of metrorrhagia during pregnancy; it reduces the hyperemia of the mucous membranes. It is not necessary to go over above thirty drops at a dose.

---

### TREATMENT OF ECZEMA OF THE EYE-LIDS.

Dr. Trousseau (*Revue Intérnationale de Bibliographie Medicale, etc.*, No. 2, 1894) has obtained unexpected results in this obstinate affection with local applications of a solution, without alcohol, of corrosive sublimate—.05-.25 gms. (one to four grains) to five hundred grams (sixteen ounces of water.) Compresses soaked in this fluid are also employed. He has observed remarkably prompt results after the ordinary means had failed. Internally, one may give quinine, and, locally employ a solution of carbolic acid to allay the itching. Salves are contraindicated as they are not well borne and sometimes cause the affection to become aggravated; they are, however, to be used in the terminal period when desquamation of epithelium sets in and then only, with caution; first trying those least irritating as pure vaseline or lard, then bismuth, oxide of zinc, ichthyol, yellow oxide of mercury or oil of cade.

Editor

RODERIC C. PENFIELD
Publisher

147-149-151 North Tenth Street, Philadelphia

TERMS:—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 28, 1894.

## EDITORIAL.

### A STUDY OF HYPNOTISM.

When positive benefit derived is made the sole justification for the use of a procedure otherwise unrighteous and even dangerous, its therapeutic value most be proven beyond peradventure before the medical profession can make its application general.

The decision must be based on the evidence of witnesses whose experience and training are such as to make their testimony credible and without prejudice. In this connection we rehearse the conclusions of Professor Benedikt, of Vienna, who has recently published a critical essay on "hypnotism," which is the most important contribution to the subject that has appeared of late. The writer is an authority on diseases, and enjoys the reputation of being a fearless, but impartial and careful investigator. His experience of hypnotism dates from 1870, when he made his first experiments, ten years before the present revival began in France, and since then he has studied every phase of it with an open, but keenly critical mind. His main conclusion can be summed up in a few words—hypnotism is real, but practically no good. This was precisely Charcot's conclusion, and it is that of most clear-headed and honest observers. It is the mean between the two extremes, held on the one side by those who deny the facts and ascribe them to imposture or bad observation, and on the other by those who claim to have discovered in them a new and powerful means of treating disease.

Benedikt is fully alive to the extreme liability to imposture and deception involved in these experiments, and points out with great force how and why this occurs; but, as he pertinently observes, it is utterly illogical to deny the original fact because it may be imitated. "Otherwise one must maintain that there are no genuine emotions, no genuine madness, and no genuine dying, because they can all be artificially imitated in such a masterly and deceptive manner."

He has the most utter distrust of all professional subjects or mediums, as he calls them, who are just as useless for disproving as for proving supposed facts, because they have got into such a state that they do not know themselves where reality ends and imposture begins, and will say or do

whatever they believe is expected of them, even to confessing imposture, whether it has occurred or not. Benedikt is, both by nature and training, particularly on his guard against deception and equally competent to detect it. "Hypnotic experiments," he says, "without objective proof, cannot in general be used as facts having the value of scientific evidence." Further, "only experiments carried out on disinterested individuals unversed in the mysteries of hypnosis have any value." In this guarded attitude, he unhesitatingly adds his testimony to that of other distinguished observers as to the reality of the hypnotic condition.

Apropos of the reality of the mesmeric condition, the following incident is related by Professor Benedikt: At the Anthropological Congress, held in Paris in 1878, Virchow asked Benedikt to introduce him to Charcot, who had then recently taken up the study of mesmerism; and they all three visited the latter's clinique. Here Charcot showed them his famous cases of "grand hysteria," and demonstrated his method of conducting the patient from one phase of the attack to another. "Surprised and astonished as Virchow was, we were both completely convinced, as completely as Charcot himself, that we were dealing with indubitable facts. I must admit feeling a certain malicious pleasure in getting Virchow to recognize these experiments, which were certainly connected in some degree with animal magnetism."

As a method of treatment Benedikt condemns it emphatically, while admitting that it possesses a certain therapeutic action, which may, perhaps, be applied with benefit here and there in a rare and exceptional case when everything else has failed. Systematic hypnotism is not only useless, but actively injurious, as it has a "demoralizing influence on the intellect, the will, and the psychical independence of the subject;" it may relieve for a moment, but eventually lowers the organism like narcotics; it is even "an offence against the security of life." This opinion is derived from experience, as it was with Charcot; but it is supported by reason and common sense. A hypnotic patient is like a rider with a bad seat, who cannot keep his equilibrium, and falls off his horse. Holding him on by a strong hand is all very well for the moment, but it leaves him more helpless than before. So with the hypnotic subject who has a weak mental balance, artificial support by "suggestion" only increases his damnation.

He would abolish the term hypnotism—surely one of the most foolish ever invented—altogether, and use mesmerism instead, or "artificial catalepsy." The latter is open to the serious objection that it already has another and a different meaning; but mesmerism is unexceptionable. It commits to no theory, and was commonly in use when all the supposed new discoveries were made half a century ago.

Professor Benedikt does not indulge in much theorizing about the nature of the mesmeric state, but he believes that it depends on some form of artificially produced tension and relaxation, and he thinks that the problem will be solved—in part, at least—when we have a proper instrument for measuring "bio-mechanical tensions." "Whether it will be constructed on the electrical, the magnetic, the chemical, or some other hitherto unknown principle, I do not know. But the facts, long ago put forward by Mesmer in classical style, point to polar opposites; and those of transference, etc., show conclusively that we have to deal with processes of tension and relaxation."

From the foregoing passage, it is clear that he considers the theory that mesmerism is purely "subjective" to be nonsense. And, indeed, those who maintain it either do not know the meaning of the word subjective or are ignorant of the facts.

With regard to the transmission of impulses without contact, which has been airily dismissed by some authorities, he declines to decide whether it is effected by direct action or only through the imagination; "although," he adds significantly, "I have seen Hansen produce startling effects on individuals known to me and studied by me, and I have myself often observed its operation in cases which were as free as possible from objection."

In conclusion, he thinks the greatest practical service rendered by the modern revival of mesmerism has been to draw the attention of physiologists to the initmate relations between the mind and the body.

## ABSTRACTS.

### "BASE INGRATITUDE."

Suits for malpractice against physicians have grown to an alarming extent in the last few years in this city. We understand that nine suits are now entered on the dockets of the various courts, and the damages claimed vary from ten to seventy thousand dollars in each individual case. One suit which was recently disposed of is about the history of all of them. After the physician had done all in his power to alleviate a blind man (charity patient), he was rewarded for his pains by having a suit for malpractice instituted against him for twenty-five thousand dollars damage.

The suit was that of H. L. Hershey against Dr. L. Webster Fox. The action was brought to recover damages for the loss of an eye after a needle operation for secondary cataract. In 1883, Dr. Fox removed a cataract from the left eye of this patient; two years subsequently a needle-operation was performed, and vision restored. In 1888 a cataract was removed from the right eye successfully; two years later this was followed by a needle-operation on the capsule, which obscured the vision in this eye; ten days after the operation inflammation developed, eye lost.

There were several important points brought out in the trial which are well worth preserving in the minds of surgeons:

*First.* It remains with the plaintiff to prove that carelessness and want of skill and due diligence were manifested on the part of the attending physician.

*Second.* It is not absolutely necessary for the physician to inform or explain to the patient the character of the operation to be performed.

*Third.* That the physician is not responsible for the results of an operation, so long as he uses a reasonable amount of skill and care.

The medical profession requires the highest skill, constant study, and unselfish devotion to the interest of mankind, and the medical man should be above the sordid acquisition of wealth. His motive for the pursuit of his chosen profession must come from his heart; but when one meets with such "base ingratitude" as these nine physicians are receiving at the hands of unmitigated scoundrels or blackmailers, it is enough to chill the softer feelings within themselves and make Shylocks of them all. With all due respect to those Nestors in the profession who constantly preach that the practice of medicine must be conducted on humane lines, and not by business methods, we say, that the students of medicine and the younger practitioners must realize and accept the fact that that day is passing away. When business methods prevail, then we shall not have suits of malpractice hanging over us to annoy, consume our time, and abstract tribute for defense; for such suits only come from those for whom we have given time, mental anxiety, even money out of pocket; our compensation—nothing. The unprecedented remarks made by one of our most honored judges, in granting a nonsuit in Dr. Fox's case, are well worthy of being repeated.

Judge Biddle said: "I do not see the slightest evidence in this case of any malpractice whatever. This man was attended for eight years, and a most serious operation performed upon him (and he paid the doctor ten dollars, which was paid the optician for glasses), in addition to attending his wife and giving him prescriptions for other matters. I think it is a case of *base ingratitude* for the services that were rendered. I grant a nonsuit."
—*Med. Bul.*

## DIETARY IN TYPHOID FEVER.

Dr. W. H. B. Aikins, (*Dominion Medical Monthly*) says:—

As I understand it, the cardinal principles of treatment in enteric fever are: (1) By free action of the bowels to remove all ptomaines and offensive materials. (2) By careful dietary to conserve the patient's strength. (3) By cautious use of antiseptics to keep the alimentary canal in as aspetic a condition as possible, and in a rational and conservative manner to treat symptoms and complications as they arise.

When the patient first comes under my care, it has been my custom to prescribe calomel in small doses in the evening and follow this up by a seidlitz powder in the morning in order to have a free alvine evacuation. If one seidlitz powder is not sufficient, a second one may be given two hours later. The patients are not purged, but it is well that there should be a free movement every second day at least, throughout the illness. I have found calomel the most satisfactory drug on account of its stimulating the flow of bile, thus assisting in making the contents of the alimentary canal aseptic; but it must be used with caution in anæmic cases.

Prior to the time of Graves and Trousseau enteric cases were sadly underfed, and though these eminent men ardently advocated a sufficient supply of nutriment, it was always nourishment in the liquid form. To quote Trosseau's words, "I am convinced that the starving system has in many cases been carried to dangerous excess, that many persons have fallen victims to prolonged abstinence in fevers," while Graves said to his pupils, "If you are at a loss to find an epitaph to inscribe on my tomb, you may use these words—'he fed fevers.'"

We find that Sir William Jenner, in an address at Birmingham, in 1879, stated that, "From the first the patients should be restricted to liquid diet with farinaceous food and bread in some form, if the appetite require it. The value of milk as an article of diet in fever, is generally admitted, but it requires to be given with caution."

Strümpell allows broth and soup thickened with sago or rice, and a role of rusk when softened by soaking. Briefly then it is seen that by rapid stages the dietary has advanced from water soup to thickened soup and a little bread.

In the journal of the American Medical Association of the 10th of February, I noticed that a gentleman reports a case of typhoid fever with a favorable termination as follows: "Diagnosis typhoid fever. Diet—ate beefteak on the seventh and eighth days of treatment, milk diet on the ninth, and solid therafter." And there is one prominent New York physician who is so generous as to allow when the patient so desires, a mutton chop, with potatoes and beer.

This, however, is, according to my view, carrying the matter to dangerous extremes.

The dietary which I have found most satisfactory and which has been allowed to my last thirty five cases of enteric fever in private and hospital practice, has been almost uniformly the same, but governed by the feelings and wishes of the patient to a certain extent.

For breakfast, if desired by the patient, a lightly boiled, scrambled, or proached egg, with a little bread and butter, milk in quantities agreeable to the patient with broths clear or thickened, such as oyster, chicken, mutton or vegetable. At intervals during the day a choice of bread and butter, bread with meat gravy, strained rice or sago pudding, custard, junket, milk toast, oysters, or biscuit with a little wine. Patients are not given more than two eggs and eight ounces of bread in the twenty-four hours.

The thirst may be quenched with pure spring water or pure mineral waters. Various other fluids are also allowed, such as barley water, egg albumen water, lemonade, koumiss, buttermilk, cocoa, tea and coffee.

This diet has not in any of my cases unfavorably influenced the temperature or prolonged the duration of its elevation, and it may be given at any stage of the disease.

The results have been uniformly satisfactory. When on the dietary the patients appear more contented. There is less tendency to nausea and gastric disturbances, less tympanites, and the diet being mixed and somewhat the same as used in health, the bowels are much less constipated than when patients are nourished on milk alone.

# SOCIETY REPORTS.

## THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

*March 28th, 1894.*

[Stenographically Reported by C. C. Mapes, M. D.]

Dr. Wallin of New York read, by invitation, a paper on

THE TREATMENT OF SCOLIOSIS, AND THE BRANDT METHOD OF MASSAGE.

(See Page 598).

DISCUSSION.

DR. CLARA MARSHALL: I was struck with one point in the paper, that is that it was not only a description of a method, but to a certain extent a defence of a case. I think that all who write upon this subject place themselves somewhat in an attitude of defence, as Brandt not being a physician, has been so often attacked as being dishonest. Anyone who has read the introduction to his book will be thoroughly convinced to the contrary. He tells in a straightforward way of his interest in the method. His first case was one of prolapsus ani in a man. He tried "lifting" through the abdomen and cured the case. The next case was one of prolapse of the uterus. I would ask Dr. Wallin to give the date of the treatment of this case, which is of great interest on account of the length of time that the cure has lasted. Having cured these cases he was emboldened to treated other cases, and so he was gradually led to success. He says himself that he believes that this method should be in the hands of physicians, and that if doctors will not others must, in order to relieve suffering.

DR. R. FLEISHER: I may speak of the work of Professor Ziegenspeck (Germany) in whose clinic I saw massage used for a number of months. He had very excellent results in chronic inflammatory troubles, and in private practice his results have been very good. Throughout, the treatment requires to be continued so long that it is almost impossible to induce the patient to come to the office or dispensary with sufficient regularity to carry out the treatment properly. The cases that I saw treated in private hospitals did excellently.

DR. J. MADISON TAYLOR: While I am not in any sense a gynecologist, I think that it is only right for me to say a word with reference to this subject of massage. In pursuing some researches in massage I have gone into this question from a literary standpoint, and I think there is ample evidence to prove that this method is of great value if properly pursued. I think that if those gentleman who know all about gynecology from their standpoint would give some attention to this method it would be to the advantage of their patients. There is considerable evidence to prove that those slow, non-American methods by manipulative procedure do a great deal of good in displacements of the uterus as well as in displacements of other portions of the anatomy. There have been very brilliant results which cannot be impugned, and of which we should have some evidence in this country if the method were properly taught and demonstrated.

DR. BENJAMIN LEE sent the following letter:

PHILADELPHIA, MARCH 27, 1894,
1532 Pine Street.

DR. JAMES K. YOUNG,
*Chairman Directors Philadelphia County Medical Society.*

DEAR DOCTOR: Since accepting your kind invitation to take part in the discussion tomorrow night I have been unexpectedly called away, and fear that I shall not be able to return in time to be present. I regret this very much, as I have no doubt the occasion would prove of especial interest to me. I desire to say, however, that I have never been able to bring myself to look with favor on intravaginal massage of the uterus and its appendages. I believe, in the first place, that a judicious combination of abdominal massage, with carefully selected localized movements of the lower extremities and inferior portion of the trunk, will accomplish as much, in the great majority of cases, as internal massage; and, in the second, that, for reasons that will at once suggest themselves, manipulation of the vulva, and the frequent introduction and prolonged retention of the fingers or hand, even of a woman, into the vagina is a practice to be deprecated. The possible relief to be obtained might be bought at too high a price.

Yours, very truly,
BENJ. LEE.

DR. M. PRICE: I agree with Dr. Lee most heartily, that no matter how much good might be accomplished, it would not compensate for the damage and the injury done by the Brandt method of massage of the uterus and vagina. This method would not break up adhesions which you find difficult to release, even with your fingers, with the

abdomen opened. Again, there is no question that vaginal manipulation even in the hands of women upon the young and undeveloped female must of necessity educate to habits of immorality. We all know the evils of self-manipulation. I do not care who is the woman or man who carries out this treatment, it is wrong, and wrong in its very inception.

Reference has been made to the cure of prolapse by this method. This I do not doubt. If the patient is put in the knee-chest position, and the uterus handled for any length of time, it will be replaced. We have all seen cases relieved by putting the patient to bed and reducing the weight and the congestion of the uterus by position and rest.

We must certainly condemn anything in the way of unnecessary manipulation in the vagina for any purpose. In all our examinations we avoid all irritation and unnecessary handling. A few years ago a member of this Society recommended the examination of women during pregnancy to correct malposition of the child, but it was generally denounced by the best members of the Society as wrong in every way.

In most cases prolapse is due to laceration of the vagina, so that there is no support to the pelvic viscera. We cannot expect to cause the ends of the torn muscle to unite by manipulation. We cannot restore what does not exist.

DR. GEORGE E. SHOEMAKER: I have seen enough of this method to feel convinced that it has a certain field which might well be cultivated. At the same time I feel that among American women the field is not as great as among the women of some more phlegmatic races. If this method is developed in this country, it should be in the hands of women physicians, and in the hands of a very few. These should be experts whom we could trust. I do not believe that it can be largely adopted by the medical profession with advantage.

DR. FRANK WOODBURY: The reference to ovarian massage recalls to mind the fact that some years ago some foreign authority recommended the treatment of hysteria by making forcible pressure on the ovaries. It occurs to me that this may be a favorable occasion to inquire into the possible bad results which may follow such treatment. During the menstrual life of a woman there are always Graafian follicles ready to rupture, and this is usually associated with more or less hemorrhage. Might such massage of the ovaries lead to localized or general peritonitis, or some other undesirable consequence?

DR. WALLIN, New York: In reply to Dr. Marshall I would state that I think the man with prolapse of the anus was treated in 1847. It was in 1861 that Brandt treated the first woman for prolapsus. He used only external manipulation, consisting of lifting, abduction of the knees, and tapotement over the sacrum. Twenty years afterward I saw the woman, who was then sixty years of age, and there never had been any return of the trouble. In Sweden the peasant women do a great deal of heavy work, and consequently prolapsus of the uterus is very common, even where there has not been laceration. None of the cases referred to have been treated in the knee-chest position. I have seen a number of cases treated by Brandt, and every one that he has undertaken has been benefited.

With regard to massage of the ovaries: the massage is always very light, and is generally given in peri-oöphoritis. You cant improve oöphoritis very much. All massage is given after the inflammatory condition has disappeared, especially if it is purulent.

As to the immortality of the treatment, I do not know what to say. The same objection would apply to all gynecological treatment. I have never heard this objection raised before, and, as I say, it would equally apply to all examinations.

DR. RANDOLPH FARIES: We know that the rotatory movement of the spine is first produced by muscular action, while the lateral curvature is a secondary effect. It is also known that each side of the body is made up of the same group of muscles functionally, and that logically to get rid of the deformity we must use the muscles which act as antagonistic to those producing the deformity. Hence it seems to me the first thing to do is to unrotate the bodies of the vertebræ, because rotation was the first thing that took place. Then correct the lateral curvature. Further, the muscles act as pulleys and levers; but there is no book giving us the compound action of muscles, and we have no means of studying the resultant of the forces if we elevate and rotate the body at the same time. Spinal curvatures are produced by compound forces, and in order to get at the true treatment requires a knowledge of mechanics, not a knowledge of medicine, hence it seems to me this is a line for good scientific study.

I have seen it stated that one cannot do much for spinal curvature after it has gone pretty far. We are pretty sure that we can do something, for the skeleton is not converted into bone until the age of twenty years, and the majority of cases present themselves between ten and fourteen years of age. Why can we not unrotate the spine in a rational way by compound movements, and thus correct the deformity?

DR. H. AUGUSTUS WILSON: Dr. Wallin has introduced a profoundly interesting subject. In reference to the plan of treatment which has been described we must consider whether it alone is curative, or whether it

must be applied in association with other remedial measures. Myotomy of the over-acting muscles has been advocated, and following this prolonged recumbency has been employed in the endeavor to obtain corelation. Adams introduced the prolonged recumbent position with the same object. Sayre used the plaster-of-Paris jacket for the same end. The object of all these methods has been to diminish the power of the over-acting muscles. This attempt to introduce a system of gymnastics has been carefully studied by Ling and other investigators, and comes to us in a practical form, but with a number or serious obstacles. Among these obstacles may be mentioned the preconceived idea that gymnastics mean a more or less large amount of cumbersome apparatus. Another objection is that a skilled attendant must be present at the time of the manipulation. One of the most serious objections is that often the method is not considered worthy of that same careful study that other therapeutic measures are, and therefore the method is left in the hands of incompetent persons. Another obstacle is the idea that if the exercise is taken once or twice a week it is ample for all purposes.

I think that the most important part of remedial gymnastics lies in the instruction of the patient in such a way that she may apply in her own home exercise that will be curative. I do not know of any class of patients who can be induced to keep up remedial gymnastics where there is the monotony of chest weights and apparatus. The patient must be taught that she can do it herself if we are to expect improvement. I have followed out these cases for a number of years, and can safely say that the only cases of scoliosis that have been cured have been relieved by gymnastic measures. The apparatus has been taken off, and the muscles and the whole system developed, and as a result they have become nearly straight. Where the patient can afford the attentions of a manipulator, it is far more satisfactory in every way, for there are cases where you cannot instruct the patient to do as you want. The methods in which the movements were to be made were demonstrated on a patient brought for that purpose.

DR. JAMES K. YOUNG: We recognize three degrees of scoliosis—the mild, the medium, and the severe. These can be distinguished by suspending the patient. If the curve entirely disappears, it is of the mild form. If it partially disappears, it is of the medium form; and if no effect is evident, it is of the severe form, in which nothing can be accomplished by massage and exercise. There are six varieties according to the position. The most common form is right dorsal scoliosis; the second is left lumbar; the third, left dorsal; the fourth, right lumbar; the fifth, right cervical; and the sixth, left cervical scoliosis.

In the mildest form a cure can be confidently promised. In the medium form a cure cannot be promised, although great improvement can occur. It is more important to direct the different forms of exercise than to conduct them personally, and to do this one must command considerable anatomical knowledge. When a person makes a movement so many muscles are thrown into action that it is almost impossible to describe them all. The attempt was made by Dr. Keating and myself to describe the muscles brought into action in the different Swedish movements. There are about three hundred different movements. We analyzed about thirty in the article upon "Physical Development" in the *Cyclopædia of the Diseases of Children.* We also obtained eight different combinations of these movements which would furnish exercise for every muscle in the body.

In the treatment of these cases it is necessary first to develop the system generally, and afterward to treat the lateral or other deformity. The principle in all Swedish movements is to develop the muscles on the convex side of the curve. I would particularly call attention to the development of the muscles about the pelvis, especially the lateral and adductor muscles. In the cure of scoliosis it is necessary to have the pelvis straight. In many of these cases there is tilting of the pelvis. The pelvis must be accurately balanced, and for this reason many of the movements are directed toward the development of the muscles about the pelvis. By carrying out these movements the mildest cases can be positively cured, while many of the medium cases can be much benefited.

DR. WALLIN: I always teach the patient some movements to be carried out at home. I have to-night shown only a few of the movements that are intended to affect the curves. The best results I saw were obtained by using "self-correcting" movements, at Dr. Tidemand's Orthopædic Institute. Cases of the first degree are always cured, and where no improvement occurs the patients learn to carry themselves that the deformity does not show to a marked extent.

---

Smith and Jones had been joking each other. Said Smith—"You can't get a sell on me, no use to try."

Said Jones—"Which hand do you feed your hens with?"

Smith replied—"With my right hand."

Said Jones—"Most people feed their hens with grain, and when they feed meat usually choose that of some other animal."
—*Boston Courier.*

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

ARCHIVES OF PEDIATRICS

for April. Dr. J. W. Ballantyne writes of

**Congenital Ichthyosis,**

stating that his object is to show the existence of a connecting link between ichthyosis of the adult and ichthyosis of the fœtus (cases that were born with a predisposition to the disease, although no manifestations may have occured for weeks.)

Of fœtal ichthyosis there are two varieties; the grave, developed probably at the fourth month of gestation, characterized by deformities or various parts of the body and by the whole body being coated by horny plates separated by furrows, and leading to death in a few hours, or days. The subject of this disease is rarely born dead. No records of either parent suffering from ichthyosis is noted, but frequently several ichythyotic children are born in succession, and a case is noted where three healthy children were borne by a woman who afterward had three ichthyotic ones by another husband.

Respiration was usually interfered with by epidermic masses blocking the nostrils, and suction, by the presence of plates around the mouth.

The appearance of a child with this disease is very repulsive, though it varies by reason of different sizes of plates and furrows, etc. The odor is very unpleasant ("Cadaveric.")

The rigidity of the plates, and the contraction of surrounding parts, is apt to cause ectropion of the eyelids, and a similar distortion of the lips, the limbs are usually kept in the fœtal attitude, aad the digits deformed like birds claws, when present.

The viscera generally show, post mortem, nothing abnormal except an unnsual degree of congestion, and a microscopic examination has shown no extension of the process along any of the mucous surfaces. No record is found of the condition of the thyroid.

The minute examination of this thickening shows that the stratum corneum is the part which hypertrophies, the interpapillary processes in the rete malpighii being elongated, but less thick than nornal, the stratum lucidum is increased in thickness, and no stratum granulosum is to be found.

Now as to the disease just described being simply a severe form of true ichthyosis, the author quotes a case which presented all these appearances, but of course not so fully developed, two days after birth, and who showed true ichthyosis in adult life.

So far as fœtal ichthyosis been hereditary, the fact of no child presenting, when born, the symptoms of ichthyosis, surviving more than a few days, seems to set the question aside; but a family prevalence is well known.

The author regrets the absence of information about thyroid development and states that one case shows improvement under thyroid feeding.

The prognosis is bad, but rectal feeding, softening of the palates by washes, ointments etc., are the means usually tried. The article will be concluded in a later number.

Dr. F. H. Southgate writes on the

**Aetiology of Hernia,**

particularly in reference to rachitis. Race he mentions, the Jews being particularly liable, the Irish almost exempt. Inherited predisposition shows itself often in cases under a year old. Elongated mesentery, incomplete formation of the muscles of the abdominal walls, and relaxation from poor health, straining from bronchitis, whooping cough, crying, phimosis, etc., and at stool.

The muscular and general weakness caused by rickets and deficient peristalsis, leading to distended weak abdominal walls, leads to this disorder much as corpulency does in adults. Some interesting statistics are given confirming the author's theory.

Dr. J. Oscroft Tonsley, giving clinical memoranda about external suppurative periostitis in the region of the ear advises an incision as soon as the diagnosis is made and if possible before pus forms. To avoid arterial injury he feels for the temporal—places his thumb on it, inserts his knife close to it, and cuts back to the mastoid, slips the knife beneath the temporal and freely incises the periosteum finding a very free incision followed by poulticing the only satisfactory treatment.

In the same number an article of Dr. W. W. Myers is quoted (from the Am. Therap.) giving the results of experiments with

**The Toxalbumen of Diphtheria.**

A diphtheria bouillon culture is made, filtered, evaporated to one-third of its bulk, then heated with ten volumes of alcohol and acetic acid. The clear liquid obtained is dialyzed for seventy-two hours, then precipitated with alcohol and dried. The white residue is the diptheria toxalbumen.

A local application of four per cent. solution of this was made in three cases of diphtheria, with recovery. Ten exposed persons were inoculated in the arm and none contracted the disease. Sixteen children exposed to croup (showing Loeffler bacillus) were inoculated in this way, and all escaped.

The symptoms of inoculation were as follows:

The second day a small red pimple, becoming vesicular by the fifth day, then pustular and drying in about three weeks. About the eight day headache, pains in loins, perhaps vomiting. No eruption of any kind, swelling of the axillary lymphatics about the ninth or tenth day. In a few cases appeared swelling of the tonsils, (without membrane) with the appearance of inflammatory sore throat, but no ulcers.

Wm. C. Dabney uses as a prophylactic in diphtheria 1-96 to 1-60 grain of bichloride in a teaspoonful of glycerine every three hours, without water, and no water is used for half an hour.

---

BROOKLYN MEDICAL JOURNAL

for April contains an article read by Dr. O.A. Gordon before the Brooklyn Gynæcological Society on

**Asepsis in Obstetrics.**

Thorough cleansing of the hands of the nurse and of the obstetrician, and the genitals of the patient, and the use of bichloride wash at every examination, are the main points of the paper. The author uses a solution of one grain of bichloride to two ounces of glycerine as a lubricant. He mentions a case where the attendant announced that he had just returned from a severe case of diphtheria at the time labor took place, and the infant, then the mother, and finally another child, developed the disease and died from it.

In the discussion which followed it seemed to be the opinion of those speaking that, while a physician might go from a contagious disease to a case of labor, he could do so safely only by the most thoroughly antiseptic precautions and one member thought it safer in such a case to avoid vaginal examination, if possible, and make use of external palpation only.

A difference of opinion was shown in regard to the comparative dangers of sepsis in abortion and in labor, and whether the washing of the liquor amnii was an offset to the enlarged uterus and the greater surface exposed as a result.

Dr. D. W. Barker describes an interdental splint intended to prevent epileptics and others from biting the tongue and lips at night. The apparatus consists of two hard rubber splints enclosing the first lower molar and the bicuspid and passing inward toward the palate—so protecting both tongue and cheeks.

Of course the teeth cannot complete close, with this in use, and, as it fits very firmly and cannot be accidentally dislodged, it has proved very satisfactory. It interferes so much with speech that it cannot be used during the day.

Dr. George Ryerson Fowler reports a case of thrombus of a varix of the saphenous vein simulating irreducible femoral hernia.

The patient had fever—had had rigors, etc. A tumor extending below Pouparts ligament four inches into Scarpa's triangle. No impulse could be felt on coughing, and an operation was done without a very clear idea of the conditions about to be found. The author thinks it very fortunate that the excessive tenderness prevented taxis as that would have probably led to septic embolism. The tumor was excised and proved to be a large saphenous varix obliterated by a clot. The patient recovered without complication of any kind.

---

THE ANNALS OF GYNÆCOLOGY AND PÆDIATRY

for April. Dr. J. M. Baldy contributes a paper on

**Conservative Surgery on the Uterine Appendages.**

It would be folly, he says, to formulate any hard and fast rules for the treatment of these patients; each case must be settled on its own merits. But from his experience he has formulated the following:

1. The vast majority of Fallopian tubes, whose canals have been closed by pelvic inflammations, have been rendered useless for all time to come.

There is no way in which we can with any certainty distinguish those few cases in which the tube might be again rendered patulous, and in experimenting in this direction practice has clearly demonstrated that infinite harm may be done as against the little good.

3. It is always well to save healthy ovarian tissue for the sake of the continuance of menstruation and ovulation where this can be safely accomplished.

4. Uncomplicated and small hæmatomata and hydrops folliculi do not, as a rule, give rise to distressing symptoms.

5. It is extremely probable that in the case of the vast majority of uncomplicated ovarian disease upon which so-called conservative surgery has been used, the relief of symptoms has arisen not from the surgery, but from the enforced rest in bed, proper feeding, nursing, and removal from care and worry; the disease being general and not local.

6. Adhesions or prolapse do not necessarily necessitate removal of the uterine appendages.

As a contrast to Dr. Baldy's paper is one by Dr. G. Betton Massey entitled "Certain Erroneous Principles and Methods in Gynæcology" in which the author inveighs against pessaries, gynæcological surgery of all kinds from the repair of a lacerated cervix and abdominal section for the removal of diseased appendages to hysterectomy for fibroids, and asserts that in electricity will be found the cure for most of the ills that female flesh is heir to.

Dr. Franklin Townsend discusses

**Scanty Menstruation.**

He summarizes his paper as follows:

1. Scanty menstruation is most usually the result of malnutrition in both young and middle aged women, married or single.

2. The primary seat of this troubled lies in the condition known as chloro-anaemia.

3. Its treatment must be directed in an intelligent manner towards rectifying this condition. Persistent patience must be persevered in with the various forms of treatment, if a permanent care is to be expected.

In this issue appear two papers on

**Hysterectomy.**

The first is by Dr. I. S. Stone entitled "Hysterectomy for Large Tumors" The author believes that it would be well for operators to have tumors carefully weighed, not estimated, and, in addition a verification of some disinterested person would add to the value of such reports. He believes that tumors will seldom be found to be as reported. He refers to the celebrated cases of Mr. Keith and reports in addition two cases of this own in which the tumors wieghed ten and fifteen pounds after removal. They were removed after Baer's method with recovery in both instances. Photographs of the patients before operation are given.

The second paper is by Dr. R. S. Sutton on "Hysterectomy for Myoma of the Uterus." Within a year, he has used the elastic ligature, pedicle outside; has tied the neck with double ligature, as in ovariotomy, and dropped it; has taken out the entire uterus; has left the neck in, but under the peritoneum, and all of these cases have recovered. His opinion is that no hard and fast rules are wanted; let each case prompt the operator to do his best in his own way. There is no rule of three for good surgery.

Dr. J. C. Irish contributes a paper on

**Appendicitis.**

From his own experience he would divide cases of appendicitis into three classes:

1. Inflammation of the appendix without perforation.

2. Appendicitis with perforation, the septic focus being walled off from the general abdominal cavity by agglutinated coils of intestine and lymph deposit.

3. Appendicitis with perforation not walled off, and in which the general abdominal cavity is invaded with sepsis,—in other words, a diffuse septic peritonitis.

From his observations he would locate the McBurney point about one inch nearer the anterior superior spinous process than the umbilicus.

With the exception of recurrent cases the treatment of non-perforating appendicitis only indirectly interests the surgeon, as the treatment is entirely medical, or at any rate should be. At the beginning of the attack the pain is so severe as to require the use of opium, in the author's opinion, though he is fully alive to the dangers of its use. For the employment of opium he lays down this rule: Use as little of it as possible and for the shortest possible time. Immediately after the relief of the severe pain the remedy he chooses in preference to all others is calomel. In fact it will often be found to give more complete relief to pain than the morphia, on account of relieving the bowels of distention from gas. He prefers calomel to the salines on account of the tendency of the latter to cause vomiting.

There is but one treatment of the recurrent cases both with and without perforation, operation. While an operation may not be so urgently demanded in recurrent cases of simple inflammation as in the perforating forms, still the disease in each case is always an inpending danger, and by it patients are rendered to a greater or less extent invalids. In regard to operating between attacks, he states that he has operated both in the intervals and at the time of acute exacerbation, and he knows of no good reason why one time rather than the other should be selected. The difficulties and dangers are much the same.

As to the second class, appendicitis with perforation, he looks upon rigidity of the abdominal muscles as an important physical sign as always indicating the presence of pus somewhere in the abdominal cavity. In any case of doubt as to the exudation, by the administration of a little chloroform the muscular spasm is relaxed and the necessary examination satisfactorily made. The author does not assent to the proposition of immediate operation in all cases of appendicitis, because he feels certain that more than one half of the cases of appendicitis are of the first class, and will fully and permanently recover with medical treatment alone. Again, by a delay of three or four days we become reasonably certain, in a majority of cases, whether we have to deal with a simple or perforating inflammation of the appendix. While it cannot be denied that this delay is attended with some danger still, on the whole, it will not be so great as that which follows the removal of the appendix in even simple cases. He sums up the treatment of this class as follows. Operate as early as possible, and remove the appendix when it can be found. All cases of this kind require drainage. Whenever a pocket of pus extends down into the pelvis, or under the liver or deep upon the median side of the cæcum, he has employed glass drainage-tubes in addition to the gauze. In the smaller or more accessible cavities the gauze alone is sufficient.

Of the third class, perforative appendicitis, not walled off, attended always by a diffuse septic a peritonitis, he say: Of all the abdominal emergencies that occur, this is as formidable and rapidly fatal as any, except hæmorrhage. It goes without saying that the only treatment is the earliest possible operation, but unfortunately, however early that may be done, with rare exceptions it will fail to avert or retard the unfortunate issue. Operation should always be done where the condition of the patient is not desperate enough to make it entirely hopeless. The author points out the fact that the symptoms of this form of appendicitis and acute obstruction of the bowels from bands of adhesions are so similar that occasionally mistakes will be made, though the prognosis is much more favorable after operation in the latter.

The remaining paper in this issue are:

"Dermoid Cyst; Broad Ligament Cyst; Vicious Union of the Cervix with Vagina," by George Erety Shoemaker, M. D., and the description of specimens of pus tubes, etc., by Dr. Joseph Price.

In the Department of Pædiatry, Dr. Edwin E. Graham describes "A case of Neurotic Œdema"

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## THERAPEUTICS.

### The use of Peroxide of Hydrogen as a Hæmostatic.

In the *New York Medical Journal*, Dr. Brewer recommends peroxide of hydrogen for the purpose of stopping hemorrhage. He has found it of great value in a number of cases. He states that it has been thought by some that the hæmostraic action of this drug is due in great measure to the fact that the peroxide-of-hydrogen fluid when brought into contact with organic matter is rapidly decomposed, giving off free nascent oxygen. This by uniting with the hæmoglobin, converts the blood, which is generally venous in character and charged with carbon dioxide, into bright arterial blood, which, it is well known, is much more readily coagulable than the vitiated fluid.

Rrewer was, however, led to question the correctness of this theory when he observed that in some of his most alarming cases the bleeding was distinctly arterial in character, and that these cases seemed to yield to the treatment as readily as those in which the oozing was undoubtedly venous.

Dr. W. G. Thompson placed the writer in possession of some facts which he observed during a series of experiments with this agent.

He observed that when a strong solution of peroxide of hydrogen (fifteen volumes or more) was brought into contact with the blood by being directly injected into the veins during life, it caused a rapid disintegration of the red corpuscles, resulting in the immediate precipitation of a semi-solid detritus which completely occluded the smaller vessels; that this effect extended so rapidly throughout the vascular system that within a comparatively short space of time the animal operated on would present the appearance characteristic of the most profound anæmia.

Thompson also observed that the application of strong solutions of this agent to mucous and serous membranes caused an almost immediate degeneration of the epithelial cells, resembling at first a rapid and exaggerated cloudly swelling, and later a complete destruction of the tissue.

In view of these facts, the writer is inclined to believe that the arrest of hemorrhage which is observed when strong peroxide of hydrogen is applied to a freshly-wounded surface results from this remarkable disintegrating action both on the tissues and the blood, rather than the simple oxygenation and rapid coagulation of the latter, for it is easy to understand how the rapid swelling of the endothelial lining of the cut blood-vessels and the soldification of the blood would result in a more or less complete obliteration of their lumen.—*Ther. Gazette.*

### The Nails.

Sulphur is especially useful in improving the nutrition of the nails. Sulphur is a normal ingredient of nail-tissue, in which it exists in a comparatively large proportion. It is consequently an excellent remedy in cases where the nutrition of the nails is perverted. In such conditions sulphur may be justly regarded as a specific nutrient remedy.

The mode of administration is an important point. It should be given regularly for a lengthened period in minute doses, such as five grains three times a day. Administered in this manner sulphur not only directly supplies the nail with an element necessary to its healthy life, but it also exerts a beneficial influence upon the composition of the blood. Sulphur is of material assistance in the treatment of the constitutional disorders upon which the trophic changes in the nails depend. This remedy possesses a decided value in the management of chronic rheumatism. From its action upon the liver and intestinal glands, sulphur is noticeable in the treatment of anemia and chlorosis. I have found sulphur of much value when the nails are brittle and marked by white spots or ridges. As an excellent local application in the same conditions, I can recommend an ointment containing from ten to sixty grains of the oleate of tin to the ounce of excipient. To this, for the sake of elegance may be added a little carmine. When rubbed along the nail and the surface surrounding it, the ointment of tin oleate improves the structure and luster of the nail.

### The Treatment of Scleroderma.

According to the Berlin correspondent of the *Medical Press and Circular* for February 14, 1894, at the last meeting of the Dermatological Society, Schutte showed a man whose illness began with pain in the knees and elbows, and with the formation of red, painful rhagades. The disease progressed slowly over the lower extremities and the right arm, and diminished greatly the usefulness of the limbs. Several methods of treatment had only a passing effect. On admission, the skin over the lower extremities and the buttocks was smooth, shining, hard and firm; bright and dark pigmented spots were irregularly scattered about. The patient could scaraely move the limbs; he mounted the steps as if the knees were anchylosed. The temperature of the skin was lowered. The treatment consisted of lengthened sitz baths, with succeeding massage with five-to-ten-per cent. salicylic vaseline. The salicylin was increased as improvement progressed. The patient gradually regained power of movement of the extremities. A small quantity of salicylic acid could be determined in the urine, so that some must have been absorbed through the skin. The favorable influence

of such treatment has been previously demonstrated in the case of a female shown to the society. In that case the improvement had been maintained.

## MEDICINE.

### The Treatment of Tonsillitis by means of Injections into the Substance of the Gland.

Prof. V. Ziemssen read a paper on this subject at the Congress of Medicine held at Weisbaden, April, 1893. Injections of a solution of carbolic acid were first recommended by Traube and Heubner in scarlantina. V. Ziemssen had found them useful in the various forms of tonsillitis, catarrhal, follicular, and phlegmonous. He was induced to try this treatment by this consideration that most cases of tonsillitis are caused by some infective virus. All recent investigations into the pathological anatomy of the tonsils have shown that in the follicles there are colonies of micro-organism of all kinds; indeed, they are found in the follicle healthy of tonsils, but it appears that, as long as the epithelium is healthy, they do no harm. When, however, the epithelium is in any way injured, they make their way into the substance of the tonsil and set up inflammation there. In the sore throat of scarlatina, in severe cases, there are nearly always small abscesses in the centres of the tonsils, from which foci inflammation spreads to the cervical lymph glands, and may cause general septicemia.

Von Ziemssen's treatment in cases of catarrhal tonsillitis consists in injection of seven minims of a two-per-cent. solution of carbolic acid into the middle of each tonsil. He uses for this purpose a specially constructed syringe. Soon after the injection pain and difficulty in swallowing diminish, and the temperature becomes normal. Usually only one injection into each tonsil is necessary. Sometimes a second is required in order to check inflammation. It might be said that the fall in temperature was due to the natural termination of the attack. From the constancy, however, with which this fall followed the injections, and the immediate improvement of the symptoms, Von Ziemssen believes the injections check the activity of the active microbes which are causing the inflammation. The injections are easy to carry out, and do not irritate the throat.

Sahli (Berne), in the discussion which followed, stated his agreement with V. Ziemssen as to the beneficial effect of this treatment both in tonsillitis and in scarlatinal sore throat. He said that latterly, instead of carbolic acid, he had been using iodine trichloride, a strong antiseptic, yet not a very poisonous body. He uses a two-per cent. solution of this body in water, and injects one or two minims of this into the tissues in different places once or twice daily. He uses this method in diphtheria with surprisingly good results. He strongly recommends this treatment for general adoption, and adds that he uses an ordinary hypodermic syringe, and that the procedure is extremely simple and easy to carry out.—*Centralblatt f. innere Med.* and *Dublin Journal Medical Sciences.*

### Olive Oil in the Treatment of Nephritic Colic.

Aussilloux (*Bull. Gener. de Therapeutique*) reports two cases of nephritic colic, occurring in elderly persons, in which the administration of olive oil produced most excellent results. The action of the oil in controlling the crises of the disorder was undoubted. How the drug acts, whether directly upon the calculi themselves or owing to its cholagogue or purgative properties was not determined. The action is apparently a reflex one, though even this cannot be accurately demonstrated clinically or experimentally. The oil stops the spasms of the ureters, as does a hypodermic injection of morphine, with the important difference that in the case of the latter remedy the relief produced is only temporary, whereas in the case of the oil it is definite. The oil seems to act in nephritic colic precisely as it does in hepatic colic, about which many observations have already been published. Regarding the administration of the oil, some practitioners prefer to give it in single doses of from 150 to 400 grammes or more. The author, however, recommends small quantities at a time, repeated as required. He refers to a singular method of administering the medicament in certain parts of France,—that is, in garlic broth; this is prepared by boiling a few cloves of garlic in water with a little salt. The broth is then poured over slices of bread soaked in the oil, constituting in this manner garlic soup. The author leaves out the bread and increases the amount of the oil from two to four tablespoonfuls. Patients take this beverage more readily than the pure oil, and it has been found to be just as efficacious. The dose may be repeated in the course of a few hours, if necessary.

## ARMY AND NAVY.

So much of Par. 13, S. O. No. 79, A. G. O. as relates to Major Peter J. A. Cleary, Surgeon, is so amended as to direct him on being relieved from duty at Fort McPherson, Georgia, to report for duty at Fort Wingate, New Mexico, instead of Fort Custer, Montana, for duty at that post, to relieve Major Washington Matthews, Surgeon.

Major Matthews on being so relieved will repair to Washington City and report in person to the Surgeon General for temporary duty in his office.

Par. 2, S. O. No. 68, A. G. O. is so amended as to direct 1st Lieut. Harlan E. McVay, Assistant Surgeon, on being relieved from duty at San Carlos, Arizona Territory, by First Lieutenant Straub, Assistant Surgeon, to report for duty at Angel Island, California, instead of Fort Huachuca, Arizona Territory.

Leave of absence for one month is hereby granted Captain Ogden Rafferty, Assistant Surgeon, with permission to apply for an extension until the 20th of May, next.

The following named officers of the Medical Department will report in person for temporary duty until further orders as follows:

First Lieutenant Charles Willcox, Assistant Surgeon to the Commanding Officer, Angel Island, California.

First Lieutenant Charles E. B. Flagg, Assistant Surgeon to the Commanding Officer, Alcatraz Island California.

## NEWS AND MISCELLANY.

### In the Name and by the Authority of the Commonwealth of Pennsylvania State Board of Health.

PROCLAMATION.

WHEREAS, Reliable information has been received by the State Board of Health that small-pox exists in the Borough of Danville, county of Montour, and that, notwithstanding the energetic and well-directed efforts of the Board of Health of the said borough, new cases of the disease are daily occurring.

AND WHEREAS, The State Board of Health also has knowledge that this disease has been carried from the Borough of Danville and county of Montour to other cities and counties in the State,

AND WHEREAS, Distance from the seat of the epidemic affords a community no security against the transmission of this disease, inasmuch as its germs may be transported the entire length of the State in twenty-four hours,

AND WHEREAS, It is the duty of the State Board of Health "to enforce such regulations as will tend to limit the progress of epidemic disease," and "to enforce such quarantine in places having no local health authorities,"

*Now, Therefore*, The State Board of Health hereby declares small-pox to be epidemic in the said Borough of Danville and county of Montour, and, with the object of preventing the further spread of the disease throughout the State, promulgates the following

ORDERS.

*First.*—All Borough Councils which have not already complied with the requirements of the act of May 11, 1893, by establishing Boards of Health, are hereby enjoined to perform this duty without further delay.

*Second.*—All Boards of Health are required to report immediately to the Secretary of the State Board of Health the existence of the first case of small-pox within their jurisdiction, and each week thereafter to report the additional cases as follows—Number of new cases during week: Number of cases released from quarantine: Number of deaths to date: Number of cases treated at their homes: Number of cases under treatment in hospital: Number of houses infected: Number of vaccinations: Precautionary measures: and also to publish an exact and true copy of such report in at least one local newspaper.

*Third.*—It is the duty of all Boards of Health to determine on a location for an emergency hospital in case this disease should become epidemic in their jurisdiction.

*Fourth.*—It is the duty of all Councils and Boards of Health to make provision for the free vaccination of such citizens as are unable to pay for the services of a physician.

*Fifth.*—All County Commissioners and Poor Directors are enjoined to hold themselves in readiness to provide emergency hospitals, nursing care, medical attendance and food for those who may be stricken with small-pox not residing in incorporated municipalities, and who are unable by reason of poverty to provide themselves with these necessaries, and also to furnish guards for quarantined houses and free vaccination, if the public safety requires the same.

*Sixth.*—All City and Borough Councils or Boards of Health and Boards of School Directors not having already in force ordinances or regulations of an effective character for the suppression of small-pox, are enjoined to immediately adopt the following equivalent odinance or regulations, and the same are hereby declared to be in force in all cities, boroughs, districts and places having no local Board of Health, in which the local sanitary laws and regulations are inoperative.

REGULATIONS.

1. It shall be the duty of every adult and every parent, guardian, or master of every minor, who has not had small-pox, or been vaccinated so as to have taken cow-pox regularly, if an adult, to be vaccinated, or in case of a minor, to cause such minors to be vaccinated.

2. No pupil shall be allowed to attend school, who has not been successively vaccinated within seven years.

3. Every school teacher or school officer who discovers a case of this disease among the attendants on the school must report the fact immediately to the local Board of Health, or, if there be no local board, to the State Board of Health. All school books which have been exposed to the infection of small-pox must be burned.

4. Whenever any householder knows that any person within his family or household has small-pox, he shall immediately report the same to the Board of Health, giving the street and number or location of the house.

5. Whenever any physician finds that any person whom he has called upon to visit has small-pox, he or she shall immediately report the same to the Board of Health, giving the street and number, or location of the house, on the receipt of which report the Board shall immediately notify the teacher or principal of every school, academy, seminary, or kindergarten in the district instructing said teacher or principal to dispense with the attendance of all pupils residing in the said family. No physician who may in good faith, in obedience to this ordinance, report a case as one of small-pox, which subsequently proves not to be such, shall be liable to a suit for damages for such error in reporting.

6. It shall be the duty of physicians and of all other attendants upon persons affected with small-pox to avoid exposure to the public of any garments or clothing about their own persons that may have been subjected to the risk of infection.

7. Every house in which small-pox exists shall be distinctly marked with a placard or flag.

8. There shall be no public or church funeral of any person who has died of small-pox, or of any person who has died of any other disease in a house in which small-pox was present at the time of such death.

9. The body of any person who has died of Small-pox shall not be exposed to view. Such body shall, immediately after death, be wrapped in a sheet which has been soaked in a solution of corrosive sublimate, in the proportion of two drachms to the gallon of water, or in an antiseptic cotton wool blanket, and privately buried within twenty-four hours.

10. No person shall unnecessarily visit any house in which small-pox is known to exist, or has existed within a period of six weeks.

11. No member of a family in whose house small-pox exists, and residing in such house, shall attend a public or private school, Sunday-school, church, theatre, circus, or any other public assembly, visit any market, shop, or store, or ride in any public conveyance.

12. No persons recently recovered from an attack of small-pox, or in whose family small-pox exists, shall go to work in any factory or mill without a certificate from their attending physician, stating that in his opinion such person run no risk of conveying the contagion, which certificate must be endorsed by the Board of Health, if there be one.

13. The period during which a person who has had small-pox, is in danger of conveying the contagion is at least six weeks from the commencement of the attack. The period within which a person who has been exposed to small-pox may develop the disease is eighteen days.

14. All rooms and houses in which small-pox has occurred, and all clothing, bed-clothing and articles of furniture which have been exposed to infection must be disinfected in accordance with the instructions of the Board of Health.

15. All cellars shall be thoroughly cleaned and white-washed, and all house-yards and privies treated with quick-lime, chloride of lime, or copperas, and kept clean.

NOTE.—For the purpose of this proclamation, all cases of varioloid shall be considered as small-pox. Any person who shall fail to obey or who shall violate the above regulations, become liable to a FINE OF $100 FOR EACH SUCH ACT OF NEGLECT OR VIOLATION.

The circular of the Board, No. 8, Precautions against small-pox; No. 31, Precautions to be adopted by Funeral Directors to prevent the spread of Contagious and Infectious Diseases; No. 41, Personal Precautions recommended to be taken by physicians in attending those suffering from certain communicable Diseases, and No. 37, on the construction of Emergency Hospitals, can be obtained of the local Board of Health, or by addressing the Secretary of the State Board of Health.

By order of the Board,

BENJAMIN LEE, M. D.,
*Secretary and Executive Officer.*

Executive office, 1532 Pine Street, Philadelphia, April 2, 1894.

**Commonwealth of Pennsylvania, State Board of Health.**

PHILA., April 11, 1894.

*To the Secretary of the State Board of Health:*

DEAR SIR:—In compliance with the resolution adopted by the International Conference of State Boards of Health at Toronto, October 6th, 1886, it becomes my duty to inform you that small-pox now exists at the following named places in this State, the number of cases at each place being named:—

Danville, Montour County, twenty-two cases, three deaths having taken place.

Washingtonville, Montour County, one case.

Lewisburgh, Union County, eleven cases, all in one house.

Riverside, Northumberland County, two cases.

Sunbury, Northumberland County, one case.

Pottsville, Schuylkill County, one case.

Shickshinny, Luzerne County, one fatal case.

Philadelphia, one case.

All of the above cases have been traced directly to Danville. The local physicians having failed, or refused, to recognize the true character of the disease, it had existed more than a month before the State Board of Health discovered it.

Harrisburg, Dauphin County, one fatal case.

Mohn's Store, Berks County, one case.

Sinking Springs, Berks county, one case.

Pittsburgh, Allegheny County, four cases.

The disease has disappeared from Reading, Tyrone Forges, Williamsport and Wilkinsburg. The outbreak at Tyrone Forges should have been credited to Danville and not to Reading.

I take the liberty of enclosing a copy of the proclamation issued by this Board, declaring the disease epidemic in the borough of Dansville and County of Montour.

All precautions are being taken as regards vaccination, isolation and disinfection.

Yours respectfully,

(Signed) BENJAMIN LEE,
*Secretary.*

---

**Resident Physicians at the Methodist Episcopal Hospital of Philadelphia.**

An examination for two Resident Physicians at the Methodist Episcopal Hopital of Philadelphia will be held on Thursday, May 3rd, 1894, at 7.30 P. M., at the Hospital, Broad and Wolf Streets.

One of the officers thus selected will go on duty August 1, 1894, and serve twelve months. The other will go on duty September 1, 1894, and serve for thirteen months.

In accordance with the Charter of the Hospital, applicants must have the degree of Bachelor of Arts in addition to that of a Doctor of Medicine. Further information may be obtained from

JOHN B. ROBERTS, M. D.,
Chairman of the Committe on Examinations,
1627 Walnut Street., Philada.

MEDICAL AND SURGICAL
REPORTER.

No. 1940. PHILADELPHIA, MAY 5, 1894. Vol. LXX—No. 18

# ORIGINAL ARTICLES.

## HYDROPHOBIA.

HIRAM CORSON, M.D., Plymouth Meeting, Pa.

Our first reliable account of rabies was by Aristotle, 322 years before Christ. He thought all animals except man were liable to the disease by inoculation of one from another. Virgil, Horace, Plutarch, and others, 130 years before Christ, gave interesting accounts of the disease; and in the second century after Christ, Galen spoke of it as the worst of diseases and recommended as a preventive excision of the wound. From the time of Galen to that of Rhazes, A. D. 922, but little was written concerning it. In the present century the writers have been numerous, as nearly all who publish works on the Practice of Medicine treat of it, but merely speak of it as it has been regarded by writers of an earlier period.

In the writings of two hundred years ago we find the disease was as accurately described as it is in those of our own times. All of them alike speak of the cause of rabies, the symptoms, the invariably fatal ending, and the means of prevention—by getting the virus from the wound or destroying it there.

Since I was appointed to report on this subject, I have carefully gone over seventy-eight long columns in the Encyclopedia of 1797; the one hundred and one pages of the Transactions of the American Medical Association, embracing 106 cases of rabies reported by the Committee of that Association in 1856; the interesting account of it contained in *Erichsen's Science and Art of Surgery;* and last, the more recent and exhaustive history of the disease given by Ziemssen in his *Cyclopedia of the Practice of Medicine*, where forty-two pages are given to the disease as it is manifested in dogs and other domestic animals, and forty pages as it is exhibited in human beings. As Ziemssen has embraced in his article all that was known up to his time, 1875, and in which he differs scarcely at all from all former writers, his declarations may be considered as reliable information as is attainable. To make copious extracts even from this voluminous report, which embraces all that is known on the subject, is unnecessary, and I shall briefly summarize it.

The cause of the disease in man is generally from the bite of a rabid dog, or the application of the saliva to an abraded surface or an incision through the skin. It *never* occurs spontaneously even in dogs.

The experiments of Herbing conclusively show that the saliva of a rabid dog is inactive when brought in contact with the healthy and unabraded mucous membrane of the mouth and alimentary canal. Pasteur and his disciples say exactly the same. In the time of Aristotle it was considered the most fearful of maladies and that by merely coming in contact with the body, or by treading upon the saliva of one affected by rabies, the disease might be contracted.

Even now there are districts in Europe, namely, the military frontier of Austria where the disease is frequent, in which the dread of it is so great, say historians, that human beings who suffer from it are shot

by their neighbors or not infrequently commit suicide. Even in my boyhood it was understood by us that if a person had hydrophobia he must either be bled to death, or smothered under feather beds. And only three or four years ago the newspapers reported a case of rabies, near to or in Atlanta, which could not be kept under the bed by four men, who were on it, but when they get two more on they succeeded in controlling him—whether by smothering or not, they did not state. How I suffered night and day when young Charles Rossith, one of my school-mates and a boy of my own age, was said to have hydrophobia and I supposed would be smothered under feather beds, I shall never forget. The young boys about the neighborhood gathered in groups agonized by what the poor lad was to undergo.

SYMPTOMS IN DOGS. — Ziemssen says that the symptoms described 200 years ago, were given as reddened eyes, drooping tail, projecting tongue and foaming mouth. These will do for the present time as well. But two or three pages are filled with an account of the many phenomena shown by different cases in the prodromic stage.

Two forms of rabies have long been recognized. The authors of long ago described them as the *Violent Form* and the *Sullen Form*. Pasteur's two forms he names: the *Furious* form and the *Paralytic* form.

The *Furious* in which there is delirium and disposition to bite. The *Paralytic* in which the animal is mute and paralyzed. In the *Furious* form the maniacal spells appear only spasmodically, while in the invals, the spasms are present only to a slight degree. The *Furious* attacks may last several hours. *No special dread of water exists.* In very rare instances do animals suffer from spasms of the throat in attempts to drink water. A discharge of foam from the mouth is scarcely ever seen. Saliva is emitted only when there is inability to swallow. When death is near, the pulse is small and thread-like, the breathing labored and the pupils dilated. At times partial convulsions set in. Death on 5th or 6th day; rarely later than 7th or 8th; never prolonged beyond the 10th; invariably fatal.

The *Sullen* or mute form constitutes only about 15 or 20 per cent; it runs a shorter course; the victims are less active; are silent and depressed; not disposed to leave home—which in the furious form the dog is disposed to do—or gnaw or bite. Paralysis of the lower jaw supervenes, with difficulty in swallowing, almost everything taken into the mouth falls out, and frothing appears. There is a changed voice, loss of appetite, constipation, rapid emaciation, paralysis of hind parts and fatal termination more quickly than in the furious form, namely, within two or three days.

In other domestic animals there are the same symptoms as in dogs. *In none of them is there dread of water.* They lap it eagerly so long as there is no difficulty in swallowing.

There are few authors who regard this affection as having been properly named hydrophobia, as persons suffering from it *have no dread of water.* Our eminent Pasteur says, emphatically, "*Dogs with rabies have no dread of water.*" This is true also in man, as has been shown in many cases.

THE DISEASE IN MAN.—In man the initiatory symptoms are said to be slight chills and heats, alternating; some pain or discomfort in the forehead; restlessness, and loss of appetite. "But one of the earliest and most persistent symptoms is an extreme degree of mental agitation and terror," says Ziemssen.

INCUBATION.—Ziemssen says "it varies extremely. In six per cent. of all cases, it varies between three and eighteen days. In sixty per cent., between eighteen and sixty-four days, while in thirty-four per cent. it exceeds sixty days." Haubner writes, "Eighty-three per cent. were within two months: sixteen per cent. within three months, and only one reached four months. The duration of the disease when fairly established is very short; rarely longer than from one to six days. In the 106 cases reported by the Committee of the American Medical Association, the great majority died within four days,—and this is the time given by most writers.

SYMPTOMS.—These are so various, if the actions of the patients are regarded, that nothing definite can be said. In some, the disease is manifested suddenly and is so evidently the result of fear and not actual disease, that the symptoms will be as varied as are the mental and nervous organizations of the patients. They are not as characteristic of the disease as are the symptoms which declare inflammations

of the brain, or the thoracic and abdominal organs. Respiration as a rule is, in quiet cases, normal during the intervals, but during the paroxysm, "it is gasping, irregular, quite rapid, and sometimes accompanied by decided dyspnœa," says Ziemssen. These convulsive respirations (by lookers-on called convulsions) are similar, I have recently been told, to those produced by the sudden entrance into a cold bath, or having cold water suddenly poured on the back of the neck, and are accompanied with spasms of the throat, and sometimes there is vomiting of a foaming, mucus, dark-colored substance resembling coffee grounds. It is useless, now, to give a long account of symptoms, as no writer claims that persons suffering with hydrophobia bark like dogs, or perform other acts which indicate that the dog's nature has been, by the virus, developed in or transmitted to man; and yet scarcely a single case occurs without it being asserted by those in attendance upon it, that the patient was fearfully affected with spasms on seeing water, and barked like a dog, and tried to bite those near to him. In Dr. Leedom's case, the young man who believed himself the victim of hydrophobia was actually going around on his hands and feet like a dog.

We are then rid of two of the symptoms: the barking and the dread of water; and if we could prevent the mental terror we would probably divest the disease of its most agonizing feature and be able to treat it as scientifically and successfully as we treat tetanus.

It is quite time that our profession with its present great enlightenment and immense resources should not stand idly, helplessly by the bed-side of the afflicted patient. We should investigate the case; discover if possible what vital organs are affected; where death has made his attack; and, then bring our weapons of defense and aggression to bear upon him and thus rescue our patient. I have no belief in the incurable character of this disease, if by any means we can rid the patient of his mental terror. I have a confident hope and an earnest belief that Pasteur or some other close observer and investigator of disease—possibly one of this audience—will find a remedy to successfully combat the disease even when at its very height.

CAN THE DISEASE BE PREVENTED? From the days of Aristotle to the present time, while the disease seemed to be rather a mysterious one, it was generally regarded as an affection of the brain and spinal marrow. One of the observers of 200 years ago queried whether it is not *wholly* a nervous disease.

Celsus, in order to prevent the virus from acting on the nerves of the part, as well as to prevent absorption of the virus into the system, recommended, as I have already said, the application of cups over the wound. And Galen, in the second century after Christ, recommended excision and cauterization of it; and from that day to this, one or the other, or both, have in all cases where danger was feared, been resorted to by physicians with almost if not quite unvarying success. The celebrated English veterinary surgeon Youat, with an experience beyond that of any one of his time, used caustic on the wound without a single failure. It is many years since I read his book, but I distinctly recollect that it was always successful if done before the accession of the disease. He used only the nitrate of silver. In our own country physicians have depended on excision or caustic, or both; and, so far as I have heard, without one failure in the thousands of persons thus treated. I have incised some and cauterized others and given to them such assurance of their safety that the mind of the patient was set at rest, and the result was good in every case. Strong, truthful, and encouraging as is the above testimony coming down to us through twenty centuries, what do we now hear the eminent Pasteur say? In a pamphlet published and circulated by one of his pupils who is trying to establish a "Pasteur Institute" for the prevention of rabies in those bitten by rabid dogs, at Red-Wing, Minnesota, it is boldly asserted that "the experience of Pasteur and his aids, with a practice vastly greater than any one else with rabies, is that *the use of strong caustics and the red-hot iron, is of no benefit, but rather an injury.*

How can we account for this rejection of preventive measures uniformly successful through thousands of years, by one who has been so great a benefactor to France? You will scarcely be willing to hear me say that it is simply because he has a preventive measure to introduce which will, if he can throw doubt on the value of the means referred to, bring him an immense revenue. I hope this is not

the cause and I earnestly hope a better, truer reason can be given for his change. But, when, in addition to this charge against the means of prevention long and successfully used, he bodly announces that the bite of even a healthy dog may cause rabies, and that it is only in a Pasteur Institute prevention can be assured, and that large fees come to him from those who at great expense flock to his institute, I feel that he places himself on a plane lower than that on which Stoy of Fry stand. Nothing could be more efficient to bring patients to him from every section of our vast country than this declaration that the bite of even a healthy dog may cause rabies, and that the means of prevention used by physicians are not useful but injurious. It is sincerely to be hoped that the Red-Wing Institute will never be established.

Having given the modes of prevention in use by the profession every where and with great success, yet as they have been denounced by M. Pasteur as more than useless, it is appropriate here to give an account of his means to protect persons who have been bitten by a rabid dog from an attack of rabies.

He says: "I found out that the virus rabiesque loses its intensity by transmission to other animals. With the rabbit it increases, with the monkey it decreases. I took the virus direct from the brain of a dog dead from hydrophobia. With this virus I inoculated a monkey. The monkey died. Then with this virus already weakened in intensity, I inoculated a second monkey. Then with the virus taken from the second monkey I inoculated a third monkey, and so on until I obtained a virus so weak as to be almost harmless. Then, with this almost harmless virus, I inoculated a rabbit, the virus being at once increased in intensity. Then with the virus from the first rabbit, I inoculated a second rabbit and there was another increase in the intensity of the virus. Then, with the virus of the second rabbit, I inoculated a third one, then a fourth, until the virus had regained its maximum intensity. Thus I had obtained virus of different degrees of power. I then took a dog and inoculated him, first with the weakest virus from the rabbit, then with the virus of the second rabbit, and finally with the virus of maximum intensity. After a few days more I inoculated the dog with virus taken directly from the brain of a dog that had just died of acute madness. The dog on which I had experimented proved completely insusceptible to hydrophobia. The experiment was frequently repeated, always with the same successful results. But my discovery does not end here. I took two dogs and inoculated them with the virus from a dog that had just died of acute hydrophobia. I subjected the second dog to my treatment giving him the three rabbit inoculations, beginning with the weakest and ending with the strongest. This second dog was completely cured, or rather became completely insusceptible to hydrophobia. "*Whoever gets bitten by a mad dog has only to submit to my three little inoculations and he need not have the slightest fear of hydrophobia.*" (1884).

I have already given you the treatment used so long by Dr. Stoy, and without a failure according to the reports—also Dr. Henry Fry's cure or rather preventive treatment in hundreds of cases without a single failure, he says. So too, a Dr. Jos. Emery, of Chester county, was for a long time celebrated as having a preventive that, when properly used, never failed in protecting the person bitten. Of this, more in another place. It may be proper to speak here also of a means considered by the people of Ohio, during a time reaching beyond this century, to be always successful in preventing the disease.

In an article entitled, "Uses of the Madstone," I find that a person bitten applied the tongue to it, and the poison was supposed to be drawn from his system. Hundreds were reported saved. What, now, shall we believe in relation to these secret remedies and the madstone? The Stoy, Fry, and Emery preventives were all vegetable substances, and therefore might have had useful medicinal properties—even if they had not, then they prove that mad dogs—dogs with rabies—are exceedingly rare, and still more rarely are persons bitten by them, and that the numerous fatal cases now reported are cases of false hydrophobia, the result of mental anxiety and fear after being bitten.

No one of you hesitates for a moment in believing that the madstone has no saving power, and, yet, hundreds of people have resorted to it and are convinced of its value in the cases used. But no cases have been presented to show that the

exemptions from the disease were due to the means of prevention used.

I will name another remedy with some proofs that it has real value as a means of prevention according to the testimony of truthful, sensible men. It is the root of the Elecampane—this was Jos. Emery's cure—Stoy's was Chickweed—Fry's a mixture of plants. Some who affect to know say it was Elecampane.

Could every case of true and of false hydrophobia be divested of the mental terror consequent on what the patient had heard of the fearful agony attendant on the disease, as reported in the newspapers and narrated by those who have witnessed cases, or had heard of them in their youthful days, I doubt not that the disease would exhibit symptoms as distinctive and as characteristic as those of chorea or tetanus.

A few years ago Gen'l W. H. H. Davis, editor of the *Doylestown Democrat*, after reading my essay on hydrophobia, published copious extracts from it followed by these remarks: "When a child I witnessed the chasing and shooting of a mad-dog, and, afterwards, listened to tales of horror, told of persons who had been bitten and who had been smothered under feather beds and otherwise hastened to the end of life, that their sufferings should cease. That day of horror has never entirely passed from my memory. I hail with satisfaction anything that may save other children and even adults from unnecessary suffering. If in this age, when the achievements of mind over matter are more clearly understood and recognized, it should transpire that disorders of the nervous system can be treated and cured by the allaying of nervous fears, humanity will lose some of its most excruciating suffering."

Such were his utterances. That the members of this Society should take this subject under consideration must be apparent to us all. As physicians we know that there is nothing in the actual diseased condition of any of the body organs—the mental conditions not being taken into account—which could produce the fearful agony, the horrible manifestation of suffering described as always being attendant on the malady. There is not a single case given to us by the newspapers, from the pen of an eye witness, but is reported as being accompanied by horrible agony and superhuman strength and an uncontrollable disposition to injure others, and yet post-mortem examinations have proved that there is no evidence of there having been disease which could have produced such suffering.

The fact that the patient afflicted with madness brings before himself the horrors which from childhood he has heard described as the invariable attendants upon it, impels him to perform the acts and exhibit the fury of which he has so often heard. Speculative theories must yield to facts. Every writer on this disease speaks of the rapid weakening of the body, day by day, until death ensues. And, yet, this poor sick person in nearly every case is restrained by cords, bound hand and foot, or held down by strong men, or partially, if not entirely, smothered under feather beds—as in the case reported two or three years ago, as occurring in or near Atlanta, where four men on the top of the bed couldn't keep the victim down, but when two more got on he was quieted—whether dead or alive was not stated.

Our profession confesses its inability to successfully cope with this disease. This should not be. We have left to the proprietors of secret remedies, and the owner of the madstone almost the entire care of those bitten by mad dogs.

It is a reflection on our noble profession that we have wholly neglected to investigate this malady and bring our remedies to bear upon it.

## THE SURGICAL RELATIONS OF THE THORACIC DUCT IN THE NECK, WITH THE EXHIBITION OF TWO DISSECTIONS MADE BY MR. WARD BRINTON.*

JOHN H. BRINTON, M. D., PHILADELPHIA.

I have here dissections illustrating the two most common terminations of the thoracic duct. I had always supposed that the anatomical relations of the ending of this duct were not more abnormal than those of any other duct or vessel in the body. But from the study of several dissections, and especially from the comparison of the descriptions given by various anatomical writers, I find great diversity in this respect. The general law is that the duct shall discharge its contents into the great veins, jugular and subclavian, at the base of the left side of the neck. This is done in several ways.

In the first of these dissections made by Mr. Brinton we have the regular, or normal type, the duct curving over the apex of the pleura and terminating exactly in the angle formed by the junction of the subclavian and internal jugular veins. In the second dissection we find the duct dividing into two branches, these forming a circle by their union above. From this circle one trunk arches outward and divides into three branches. Two of these empty into the subclavian at the distance of one-quarter and one-half an inch from the internal jugular junction. The third branch empties into the internal jugular. Between these divisions passes a communicating branch. A large branch is also given off from the right side of the circle. This passes upward, turns to the left, and, deeply seated, crosses the neck transversely. The last portion of this branch was uninjected.

From the examination of these dissections the two typical terminations of the thoracic duct as described by Meckel can be studied. In most cases it empties into the angle of union of the internal jugular and subclavian veins by one trunk; when more than one trunk exists the terminations of the thoracic duct are in both the internal jugular and subclavian veins. The duct as stated by this observer rarely opens into only one of these two veins.

In Quain's *Anatomy*, I find that the thoracic duct often divides into two or three branches, which terminate separately in the great veins, as in the second dissection on the table. Sometimes these several ducts again unite in a common trunk, and occasionally one of the branches may pass across and empty into the veins of the right side of the neck. The duct has also been known to terminate in the vena azygos. According to Sappey, there are many varieties of termination; Professor Harrison Allen, in his *Treatise on Anatomy*, states that the thoracic duct may empty into the jugular, azygos, and left innominate vein; infrequently it may be double. Sometimes as many as six terminal vessels are present, which are received into the subclavian, jugular, vertebral, and axillary veins.

The irregular terminations of the thoracic duct are alluded to by Henle and by Breschet. The latter, in his *Système Lymphatique*, describes minutely the many varieties, and instances one case, cited by Haller, from Bartholin, of the communication of a duct branch with the vena cava.

The formation of circles, or insulæ, as seen in the specimen before you, is also referred to. I might mention that the multiple termination of the duct is frequently met with in animals.

Hyrtt, so accurate and practical, tells us that the varieties of termination of the duct are very numerous, and do not in the least interest the practical surgeon. I cannot but think that the latter remark is too sweeping, especially in those cases where any portion of an arch formed by irregular terminal branches reaches high into the neck. If drawn upon or stretched by contracting and indurated tissues, and during operation, it might be easily cut

*Read before Philadelphia Academy of Surgery, April 2, 1894.

or torn. In an instance where a duct branch passes transversely for a considerable distance to empty into the subclavian vein, it certainly might be readily endangered. It seems to be, therefore, that the possibility of irregular and manifold endings of the thoracic ducts must be considered by the practical surgeon, and that in operating in this deep seated, dangerous region he should bear in mind its normal abnormalities.

That I have not overrated the chances of accident to the thoracic duct, its terminations, will, I am sure, be evident to the Academy on the presentation of the next paper by Professor Keen.

## PINKROOT POISONING.

JAMES E. FREE, M. D., BILLINGS, MONTANA.

March 18, 1894, 10 A. M., Rolland M., two years and four months old, was given seven spoonfuls of an infusion of pinkroot and senna, for worms. At 2 P. M. he began to cry violently without cause, and kept it up until 3 P. M., when he looked, and acted queer; 4 P. M. threw his head back on the pillow, like a victim of meningitis, indulged in the hydrocephalic cry, began to jerk all over, and soon became unconscious.

7 P. M. temperature 107°, head hot, skin dry, respiration 50, bubbling râles over chest, breathing of the Cheyne-Stokes type. The inhibiting control of the respiratory centre over breathing was lost. The diaphragm seemed to act spasmodically. Breathing was at times stertorous, sighing, moaning.

Heart's action was irregular and tumultuous. The tongue was about natural in color and moisture. A bright red spot looking like hectic flush was on either cheek.

Pupils were widely dilated. Cornea presented the glazed appearance of a person in rigor mortis.

Pulse was too rapid to count. The most pronounced symptom was clonic contractions of the muscles. The chin, mouth, ears, scalp, eyebrows, were moved spasmodically as if the patient was subjected to an acute choreic attack. Abdominal muscles jerked almost constantly. Head was thrown back, and legs stiffened synchronously twice in a minute. Arms were constantly in motion. The bed, a large one, was rattled by the movements of child. Patient had been constipated for two days, and a nurse who was taking care of the child's mother in confinement diagnosed "worms," and administered the medicine to physic them out. The intestinal canal was in continuous motion, judging from the gurgling within the abdomen.

An injection of hot water brought away four copious evacuations, foul smelling, and containing much undigested food, and many berry seeds. The child had been fed a hard-boiled egg for breakfast.

After the stools, the sphincter was relaxed and patulous. Nothing was retained unless child was turned on his stomach, with trunk higher than head. This position interfered with respiration. No urine was passed during the day.

The mother of the child is an hysterical woman, below the average in intelligence, and has thyroid enlargement. The boy was not bright; bigheaded; and had the look of an epileptic. Symptoms increased in violence, and child died at 12 M.

The United States Dispensatory mentions poisoning by pinkroot as a remote possibility, and also says that it is combined with laxatives which prevent its narcotic action from being dangerous. In this case there was no amelioration of symptoms after profuse diarrhœa.

AUTHORITY that needs to be frequently asserted does not generally last long.—*Milwaukee Journal.*

## FREEDOM FROM RECURRING APPENDICITIS AFTER EVACUATION OF THE ABSCESS AND RETENTION OF THE APPENDIX.*

JAMES M. BARTON,† A. M., M. D.

At the last meeting of the American Surgical Association I reported nine recoveries from operations for appendicitis in which the appendix was not removed. These were all cases of ruptured appendix with circumscribed abscess, with no general peritonitis and no symptoms of obstruction.

The operation consisted in opening the abdomen and using sterilized cheese-cloth to hold the movable intestines back and to protect the general peritoneal cavity while the abscess was opened and emptied. Drains were then introduced, some of the cheese-cloth permitted to remain, and most of the wound closed. No attempt was made to find or remove the appendix.

Before considering the later condition of the appendix in these cases I wish to report, briefly, five more cases upon whom I have operated in the same manner, all of whom also recovered.

Mr. B., aged twenty-three years, a patient of Dr. Cline, of Jersey Shore, Pa. He was operated upon August 24, 1893, on the seventeenth day of the disease.

William C. M., aged twenty years. The operation was performed at Jefferson College on August 28, 1893, on the third day of the disease.

Harry S., also aged twenty years. I performed the operation at the Philadelphia Hospital, September 4, 1893, on the seventh day of the disease.

Richard B., aged forty-four years. The operation was performed at the Jefferson College Hospital, September 17, 1893. It was the third attack, and the present one had existed for thirteen days.

Miss V., aged twenty-two years. The operation was performed November 10, 1893, on the third day of the disease. She was a private patient of Dr. M. B. Dwight, of West Philadelphia.

My object in bringing this subject to your notice is to exhibit several of these patients and to read reports from most of the others to show that none, whose histories I have been able to follow, have been at all troubled by the retained appendix, and to learn if the experience of the Fellows of the Academy have been similar to my own.

It is becoming widely recognized that this method of operation is accompanied by a low rate of mortality. Richardson in this country, Tait in England and Reclus and Schmidt on the Continent, as well as many others, content themselves in these cases of local purulent peritonitis with protecting the peritoneal cavity and draining. Others, however, still consider that no operation is complete without removing the appendix. In the March number of the *Annals of Surgery*, Fowler advises, in these cases, the removal of as much of the appendix as can be done without separating adhesions, but considers it necessary to remove the rest of the appendix at a second operation.

Of these fourteen cases, eleven were operated upon by myself during the last two years. All on whom I have operated in this manner have recovered, and none, that I am aware of, have had any trouble with the retained appendix since.

As the mortality has been much greater when I have removed the appendix, I now rarely do so unless the appendix is unruptured, or, if ruptured, only when general peritonitis has occurred.

Of these eleven cases I have been able to follow the history of eight, several of whom are here to-night for examination.

The three whom I have not been able to find were hospital cases; two of them were brought to the hospital by physicians. If either of these had had a recurrence needing surgical aid I should probably have known it.

Of the eight whose histories I have been able to follow, none have had the slightest symptom referable to the appendix since the operation. No tumor is to be felt, and no tenderness. Indeed, they all appear to have been singularly free from diseases of all sorts since the operation.

Mrs. C., aged thirty years, is here this evening, and will permit us to examine the region operated upon. The operation was performed November 29, 1892, and though she has been using the sewing-machine steadily ever since, she has enjoyed the

*Read before the Philadelphia Academy of Surgery, April 2, 1894.

†Surgeon to the Jefferson College Hospital and to the Philadelphia Hospital.

most robust health. The right iliac fossa is apparently entirely free from disease.

I also present Wm. C. M., aged twenty years. I operated upon him at Jefferson College Hospital, August 28, 1893. He has been in perfect health in all respects since the operation, and there is no evidence of disease in the right iliac fossa.

Harry S. has also been kind enough to come here. I operated upon him September 4, 1893, at the Philadelphia Hospital. He also has been in perfect health since the operation, and presents no evidence of disease anywhere.

Dr. Marshall, of Milford, Delaware, informed me a few days ago that the patient, Mrs. S., on whom I operated for him on February 26, 1892, has enjoyed perfect health ever since, and that on examination he has been unable to find any tenderness on pressure or any tumor in the right iliac fossa.

Dr. Beary, of the Falls of Schuylkill, reports that Mrs. R. T., on whom I operated for him January 20, 1893, has been in perfect health since the operation.

Dr. Cline, of Jersey Shore, Pa., reports that Mr. B. has been in perfect health since the operation; indeed, in better health than for a number of years before.

Dr. Dwight, of West Philadelphia, reports his patient, Miss V., as in perfect health since the operation, and on a recent examination of the seat of the disease there is no tenderness and no tumor to be felt.

Dr. Chandler, of Centreville, Del., reports: "The patient, Mrs. M., on whom you operated for me, April 3, 1893, has made a perfect recovery, and has been perfectly well ever since." He adds, "that from the operations in which he has participated he thinks the removal of the appendix in these cases is not required if good drainage is established. The appendix will take care of itself."

From the uniformity with which full and complete recovery has occurred in the few cases that have come under my care, it looks as though the appendix is not very liable to give trouble if permitted to remain. Indeed, I think it is quite likely, in cases such as we have been considering, that the opening from the appendix into the intestine is closed early in the attack—closed quite as firmly as any ligature would close it, and there is but little probability that fecal matters will ever be again able to enter the appendix either to cause a fecal fistula to follow the operation or to start another case of appendicitis in the future.

If it were not firmly closed, the pus would never have broken through the walls of the appendix, or, having broken through, the resulting abscess would not have increased in size, but would have emptied itself through the appendix into the bowel.

To further illustrate the strength of this obstruction at the base of the appendix I have observed, in several cases where fecal fistula followed appendicitis, that in none did the feces make their exit through the appendix, but through other portions of the intestines, showing that the inflammatory deposit closing the appendix was even stronger than the healthy bowel.

The mortality following operations for appendicitis is mainly due to general septic peritonitis and to intestinal obstruction.

If we will look into the cavity of a fully-developed abscess, such as we have been considering, we can readily see how these complications may follow the search for or removal of the appendix. The cavity of the abscess is lined with a thick layer of grayish, poorly organized, aplastic lymph, filled with micro-organisms. The appendix lies buried beneath this lymph, and its cavity communicates freely with the general abscess cavity. The opening can occasionally be seen, and is often the only guide by which the position of the appendix can be recognized.

To tear up this fragile and infected lymph, and distribute it through the peritoneal cavity while searching for and liberating the appendix, would greatly increase the probability of establishing a general septic peritonitis.

Intestinal obstruction following operations for appendicitis is probably due to kinking of the recently separated intestines. As they reunite, covered and stiffened as they are by inflammatory deposits, they cannot adjust themselves as readily as at the first formation of the abscess.

To avoid any misunderstanding, let me state that it is only in cases of circumscribed abscess that I have been permitting the appendix to remain.

When the appendix is still unruptured, or when it has ruptured and general peritonitis has occurred, or when obstruction is present, I am in the habit of removing it.

# VAGINAL HYSTERECTOMY.*

JOHN B. DEAVER, M. D., PHILADELPHIA.

MR. PRESIDENT AND FELLOWS:—I will not offer an apology for bringing before this body a paper upon "Vaginal Hysterectomy," as I am convinced that this line of work should not be delegated solely to those who work in the field of gynecology, but that it belongs as well to the general surgeon. In support of what I have said may I be privileged to ask the question: Is not the surgeon who meets with all forms of surgical complications better prepared to meet such than the limited specialist who has not had a general surgical training? Furthermore, if the general surgeon in the pursuance of his work has kept up his anatomical work, and opportunity has been given him to observe in hospital, as well as in private practice, the class of cases I propose to discuss this evening, I think you will agree with me that a paper on this subject by a general surgeon should not be considered out of place.

In the discussion of this subject I will consider it under the following headings:

Symptoms, diagnosis, prognosis, complications, anatomical relations, preliminary treatment, methods of operation, operation, report of cases.

SYMPTOMS.—The symptoms of carcinoma of the cervix may be so slight at first that the patient will pay no attention to them, but will attribute the sensations experienced to the change of life or menopause, at which time cancer in this locality usually makes its appearance. From the insidious character of the invasion, considerable involvement will generally have taken place ere the case comes to the notice of the attending physician or surgeon. A slight hemorrhage is noticed, following exertion or coitus, and occurring between the regular menstrual periods. This usually does not alarm the patient until it becomes a frequent occurrence. It has been compared to the hæmoptysis of early pulmonary consumption, but is unlike it from the fact that there is no active destructive change going on as yet. A leucorrhœal discharge is present, although without the characteristic cancerous odor. In the first stage the general or constitutional manifestations of cancer do not present themselves. Pain, however, is one of the earlier symptoms. There may be disturbance either of the digestive or nervous system, or of both.

Following this preliminary stage there is usually a period of latency when the disease seems to "rest upon its oars," prior to the second stage, when all the symptoms are present to a marked degree. The hemorrhages are more frequent, and at times are profuse. There is also present a sero-purulent, irritating discharge, with a penetrating, foul odor, and by contact with the internal and external genitalia giving rise to irritation and pruritus, which often cause as much distress as the primary disease. Pain is severe and radiating in character, and is felt most in the lumbar region. The uterus may be fixed or movable; as the disease progresses the uterus becomes fixed by extension of the disease to the surrounding pelvic structures. Examination with the speculum is often unsatisfactory, unless ulceration or granulation tissue be present; the finger more readily detects the character of the tissue, recognizing neoplasm from its consistency.

The general condition of the patient during the second stage undergoes a marked change. The digestion is very much impaired; anorexia, constipation, etc., are present, and give rise to systematic malnutrition. As a result of this general disturbance, what is known as the "cachectic stage" makes its appearance. The skin is dry and rough, and its color is changed to a muddy yellowish-brown tint.

DIAGNOSIS.—The conditions from which cancerous disease of the cervix might be defferentiated are the following: Lacerated cervix, with cervical catarrh; erosion of the cervix; specific ulceration; mucous patches; papillary growths; vaginitis; myoma, and sarcoma.

The diagnosis of the cervical carcinoma is in the main easy, as the cases are usually seen after positive ulcerative and other gross changes have taken place. Where there is simply thickening of the mucous lining of the cervix, with infiltration of the walls, and particularly where the cervix has been torn, it becomes somewhat difficult to differentiate from a long-standing case of cervical catarrh. When, in

*Read before Philadelphia Academy of Surgery, March 5, 1894.

addition to the above conditions, the cervix presents a nodular appearance from occlusion of the cervical glands, the difficulty is increased. This latter condition, however, should not be mistaken for carcinoma, as the nodules are characteristic of malignant infiltration.

If ulceration is present, and the ulcers present a punched-out, ragged appearance, bleeding freely from the slightest touch, suspicion should be aroused. On the other hand, ulceration consequent upon erosion of the cervical mucous membrane is regular in outline and the surface of the ulcer smooth.

Specific ulceration of the cervix, chancral and chancroidal, is rarely seen, and bears little or no resemblance to carcinoma, and in connection with the history of the case, age of the patient, etc., should not cloud the diagnosis.

Mucous patches and papillary growths are more likely to be confounded with the disease than the two preceding conditions; these are, however, distinguishable in that they are more numerous and more widely distributed.

The discharge which accompanies vaginitis in no way resembles that resulting from carcinoma.

Myoma of the cervix might be confounded with a single carcinomatous nodule, but differs from the latter in the absence of infiltration, inflammation, and adhesion of the overlying mucous membrane.

In incipient carcinoma of the mucous lining of the uterus before the body has become involved the only symptoms are the presence of a sero-sanious discharge, not necessarily accompanied by odor, and the general appearance of anæmia with debility and digestive disturbances. Pain may or may not be a feature of the case. These indefinite symptoms, together with the failure to respond to well-directed treatment, and the absence of disease of the uterine adnexa should warrant dilatation and curettement for purpose of diagnosis.

In carcinoma of the body of the uterus the presence of a serosanious discharge with the characteristic odor, associated with frequent hemorrhage and enlargement of the fundus, would warrant curetting and microscopical examination of the particles of tissue removed. This may be done without anæsthesia.

Sarcoma of the uterus is capable of giving rise to symptoms similar in many respects to those of carcinoma. While it is not always possible to differentiate between these affections, they each have symptoms peculiar to themselves.

The symptoms in favor of sarcoma are the presence of a rapidly-growing tumor of the uterus appearing rather earlier in life than carcinoma; hemorrhage, which is more or less constant, and severe pain.

The diagnosis of sarcoma can often be established by a digital examination, when the cervix will be found less patulous than in carcinoma, the tumor presenting the form of a polypoid growth, It may be necessary to dilate the cervix to explore the interior of the uterus, when, if a mass be found, a portion of it may be removed and examined.

PROGNOSIS.—As to the probable outcome of the operation of a vaginal hysterectomy for carcinoma, it is too early in the history of the operation to draw definite conclusions, but the results thus far have proved that especially early and even later operation prolongs life. There is no doubt but that removal of the uterus for carcinoma offers a longer immunity from return than does operation for the same disease in other parts of the body, if done early.

COMPLICATIONS. — Fatal attacks of uræmia may follow, though it is rare to have eclamptic convulsions.

By extension of the disease the bladder and rectum become involved, and as a result cystitis or vesico-vaginal or recto vaginal fistula may arise to add to the already deplorable condition of the patient. Peritonitis from extrusion would cause a speedy termination of the case, as would an embolus.

Pregnancy is a dangerous complication, as septicæmia or fatal hemorrhage is likely to ensue if the case be permitted to go to full term.

ANATOMICAL RELATIONS.—The relations of the ureters are of so much importance in this operation that I have thought it worth while to describe their course. They extend from the termination of the pelvis of the kidney to the bladder, passing through the laminæ of the subperitoneal connective tissue. Their average length is about twelve inches. At their commencement they lie about three inches apart, but on nearing the base of the bladder they

run foward and inward and pierce its wall, and at their termination are separated by a distance of about an inch and a quarter.

We may describe them as consisting of three portions—viz., abdominal, pelvic, and vesical. The abdominal portion is in relation posteriorly with the psoas muscle and its fascia, the genito-crural nerve, and the common iliac artery. Anteriorly they are covered by the peritoneum, and on the right side lie partly under the caput coli and ascending colon, and under the descending colon and sigmoid flexure on the left. About the middle of their course they are jointed by the ovarian vessels, which cross them to descend into the pelvis along their outer border. At the brim of the pelvis the right ureter lies just behind the peritoneum, where it can be seen with the ovarian vessels. On the left side the relations of the ureter to the sigmoid flexure depend entirely upon the length of the meso-sigmoid. Thus in one case the ureter may lie behind the sigmoid vessels, and in another directly behind the intestines. After crossing the psoas muscle it crosses obliquely over the common iliac artery above its bifurcation, dropping into the pelvis at this point.

The pelvic portion runs in front of the sacro-iliac synchondrosis, then upon the obturator internus muscle and its fascia, finally leaving the pelvic wall to join the bladder. It lies at first usually to the inner side of the internal iliac artery, subsequently to the outside, and is again crossed by the ovarian viens and artery, which leave it at an acute angle. It then descends in the lower cellular tissue to the floor of the pelvis in a forward direction, passing directly under the uterine artery, and through the uterine plexus of veins and beneath the base of the broad ligament. Finally it crosses the upper third of the vagina to reach the vesico-vaginal interspace, and pierces the bladder opposite the middle of the vagina.

The vesical portion, about half an inch in length, runs obliquely downward and inward through the coats of the bladder to open on the mucous surface at a distance of about an inch to an inch and a quarter from its fellow, and the same distance from the internal urinary meatus.

The uterine artery leaves the lateral pelvic wall at a point just above the ischial spine, reaches the vaginal wall at the level of the os externum, and then runs upward along the side of the uterus to reach the fundus.

Preliminary Treatment.—Much depends upon the preparation of the patient for operation. The most careful antisepsis of the vulva and vagina should be carried out. It is the practice of some surgeons to have the hair covering the soft parts removed ; I do not believe this necessary if this region be thoroughly scrubbed twice a day with some good detersive soap for two or three days prior to the operation. The vagina should be cleansed with soft soap, and then both the external genitals and vagina irrigated with a 1:60 carbolic acid solution containing an amount of bichloride of mercury to make it equivalent to 1:4000. The bowels should likewise be carefully regulated, and a mild laxative administered for a few days before operation to thoroughly clean out the lower end of the alimentary canal. If there be present granulations covering the cervix or occupying the uterine canal, or should the cervix be eroded and accompanied by a fetid discharge, it would be wise at first to curette away the granulation tissue exciting the discharge, and the vagina subjected to bichloride irrigations twice or thrice daily, the frequency depending on the character of the discharge.

Methods of Operation.—In the operation of vaginal hysterectomy one of three methods are practiced—the clamp, the ligature, and that by enucleation (Langenback's). There is no doubt but that the method by enucleation is the ideal one, and should be adopted when the case is suitable for it.

The enucleated method consists first in liberating the cervix by carrying two elliptical incisions through the vaginal wall in front of and behind the cervix, or by a circular incision carried around the cervix, the dissection being made close to the cervix. This should be the rule whatever method be employed. In the removal of neck tumors in the immediate neighborhood of large vessels, or, in fact, any tumor occupying an important vascular locality, the surgeon follows the practice of dissecting close to the tumor. The second step in the enucleation method is in making a sub-peritoneal dissection of the uterus. I think this should be the operation of choice in the early cases at least.

Between the clamp and the ligature method there is in my mind no doubt of

the superiority of the latter. I grant there are a few cases where the clamp method is probably the better operation, but these constitute the exception. The ligature method of vaginal hysterectomy is as much superior to the clamp as is the dropping of the stump in the supra-vaginal, having tied off the uterine appendages and ligated the uterine arteries, over that of the *serre-nœud*. The ligature is surgical, while the clamp compared to it is unsurgical.

In the selection of any operation, that which will leave the patient most comfortable, not, of course, exposing her to a single additional risk, should in my judgment be the one of choice. I am frequently confronted with the argument, "Why, the clamp method can be done in fifteen minutues and less." In answer to which my reply is, The ligature method can be done in thirty to forty minutes. The question of a few moments longer in doing the opertaion is of no import, as, if the case is suitable for a hysterectomy, there will be no shock. The loss of blood in the ligature method is no greater than that in the clamp, if done properly, and the security against secondary bleeding is much greater. The ligature method is one that can be made a strictly aseptic one, and maintained so throughout, while in the case of the clamp there is always some suppuration following, thus exposing the peritoneum to infection from without.

The question may arise, Why not close the wound in the vault of the vagina? The wound closes itself. I have observed, and demonstrated after the removal of the uterus, the almost perfect apposition of the cut surfaces; therefore, have never been able to see the necessity of introducing sutures. If bleeding follows reaction from the anæsthetic, and the wound in the vagina has been closed by sutures, it may be the cause of a subsequent abscess, while in allowing the edges of the wound to oppose naturally, and introducing a little packing of iodoform gauze into the vagina, not carrying it into the pelvic cavity, the blood finds its way into the vagina and is taken up by the gauze. By the time reactionary or consecutive bleeding, if you see fit to call it such, would occur, the wound in the vagina would not yet have been sealed off; therefore it finds its way out of the pelvis.

In either the ligature or the clamp method, when the cervix is entirely destroyed, thus making it impossible to grasp it with a vulsella or pressure forceps to pull the uterus down, my practice is to introduce a tenaculum into the uterus, by which I am able to make slight traction, and thus steady the organ; this allows me to free the vaginal walls and expose the supra-vaginal portion of the cervix, which I grasp with the vulsella, and thus command the uterus through the remaining steps of the operation.

*Operation.*—The bowels and bladder having been emptied, the patient is anæsthetized and placed in the lithotomy position, with her limbs held by assistants. A Sims' speculum is introduced and the cervix uteri exposed. The cervix is then grasped either by a vulsella or a pair of pressure forceps, the latter being less likely to slip or tear out. Traction is made upon the uterus, drawing it downward and forward to expose its under surface. An incision is carried across the exposed surface to the situation of the internal os, or as far away from the eroded tissue as possible, and with the fingers the posterior wall of the vagina and the areolar tissue are freed from the uterus down to the peritoneum. The forceps holding the uterus are then carried downward, and the incision continued to make it encircle the organ. The structures in advance of the uterus are dissected away in the manner before described, great care being observed to keep close to the body to prevent injury to the bladder; having reached the vesico-uterine folds of the peritoneum, the vagina is thoroughly irrigated. The recto-uterine and vesico-uterine folds of the peritoneum are now broken through, and, if the operator so desire, a small piece of gauze or sponge introduced to prevent prolapse of the intestine; this I do not believe, however, to be essential. The female blade of the clamp is then introduced along the palmar surface of the finger, which acts as a director. The blade of the clamp is made to hug the under surface of the broad ligament, and the end of the blade is made to pass beyond its upper limit. The handle is depressed to make the end appear above the upper surface of the ligament, the other blade introduced, and the clamp locked. The opposite side having been treated in the same manner, the attachments are severed and the uterus removed. Should difficulty be experienced in applying the second clamp, the attach-

ment of the side already clamped may be severed, and the body of the uterus loosened and delivered, when the clamp can be easily applied.

A piece of sponge or gauze is introduced, and the vagina is irrigated; gauze is loosely packed around the clamps to prevent ulceration of the soft parts from pressure, and a light packing placed in the vagina to act as a capillary drain.

The clamps may be removed at the end of the second or third day. In removal of the uterus by the ligature method the early steps are the same as in the clamp operation. Having freed the uterus from all its surrounding tissues except the broad ligaments and the peritoneum covering the fundus, the vagina is thoroughly irrigated. The broad ligaments are now to be ligated. An aneurism needle, curved on the flat and set at right angles to the handle, is threaded with a silk ligature and passed through the base of the right broad ligament a short distance from the cervix; this secures the uterine artery. Successive ligatures are then applied until the entire ligament is tied off. As each ligature is tied the included portion is cut free from the uterus. Having ligated and secured the right ligament, the left is treated in the same manner.

If there be an elongated body, as is often found in uterine carcinoma, great difficulty may be experienced in ligating the entire ligament upon one side without tying off and removing a portion of the ligament of the opposite side. By adopting this course the organ can be pulled down and the remaining ligatures easily applied. As the ligatures are being tied down the traction of the uterus should be relaxed. The uterus having been freed from its ligamentous attachments, the peritoneum is broken through and the organ removed.

After the uterus has been removed, it is the custom of some surgeons to close the opening in the vagina. I do not practice this. The cut surfaces approximate themselves, and further favor drainage if we simply pack the vagina and do not stitch.

### REPORT OF CASES.

Case I.—Mrs. C., aged thirty-five years, was admitted to the German Hospital with an extensive carcinoma of the cervix, which had recurred after a previous curetting and now demanded the removal of the whole organ. The patient was carefully prepared for operation, receiving several antiseptic douches daily for a few days, and also boric acid baths. The anterior and posterior walls of the vagina were carefully dissected up, and the uterus freed and its broad ligaments tied off in sections. The ovaries were removed with the uterus. Light packing of iodoform gauze introduced into the vagina.

The patient made an uninterrupted recovery, and was discharged in three weeks.

Case II.—A. B., aged forty years, and unmarried, was admitted to the German Hospital with the following history: For some time past she had been suffering from profuse uterine hemorrhage. Menstrual flow was excessive and painful. Diagnosis of carcinoma of the uterus was made, and total removal of the organ advised.

*Operation.*—The mucous membrane of the anterior vaginal wall was dissected up until the fundus of the uterus was reached. Treated posteriorly the same way. The broad ligaments were tied off in sections—four on either side of the uterus, which was now removed with the ovaries and tubes. Ligatures now cut short. A light packing of iodoform gauze was introduced into the vagina, and a pad placed over the vulva. The packing was changed on the fourth day; on the seventh day a slight odorous discharge was noticed, which disappeared on the twentieth day after operation. No signs of peritonitis.

The patient was discharged on the twenty-fourth day. Microscopical examination of specimen proved the correctness of the diagnosis—carcinoma in early stage.

Case III.—Mrs. K. G., aged thirty-five years, admitted to the German Hospital with a history of curetting at another institution for carcinoma of the cervix. At the time of admission a granular mass was found involving the entire cervix. She was again curetted. Six days later vaginal hysterectomy was performed.

*Operation.*—The cervix was drawn down by means of a tenaculum, and a silk thread introduced through both lips of the same. The anterior vaginal mucous membrane was carefully dissected up from the exterior surface of the uterus. The posterior surface was similarly treated. A small vaginal cavity complicated the enucleation considerably. After the uterus had been

freed of the vaginal mucous membrane, clamps were applied to the broad ligaments. The organ was removed by cutting between the uterus and the clamps. The part was irrigated with boric acid solution, and the vagina packed with iodoform gauze. An antiseptic pad was applied to the vagina. The clamps were removed on the fourth day. Recovery uninterrupted.

CASE IV.—Mrs. K., aged thirty-four years, admitted to the German Hospital with a granulating mass of the cervix. An attempt was made to curette the mass away, but it was found to be too extensive.

*Operation.*—The cervix was firmly held with a vulsella forceps. The anterior vaginal mucous membrane was dissected away from the uterus. The posterior surface was treated similarly. The broad ligaments were tied off in sections—three ligatures upon either side of the uterus, which was now removed; the vagina was irrigated and packed with iodoform gauze. The dressing was removed on the eighth day, the parts irrigated, and dressing reapplied. The patient made a successful recovery, being discharged upon the fourteenth day.

# TRANSLATIONS.

## THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

### PERMANGANATE OF POTASH IN THRUSH.

Drs. Troitski and Karntski (*Gazzetta Degli Ospitali*, No. 6, 1894) regard the permanganate of potash as the most efficacious remedy in the treatment of thrush, in children. Besides application of an alkaline solution they also employ the permanganate locally in solution. A 2-4 per cent. solution of the bicarbonate of soda may be employed for alkaline irrigation, or in very grave cases a saturated solution of this substance. Besides this the physician should touch, two to three times a day, the affected spots with the following:

℞

| | | |
|---|---|---|
| Permanganate of Potash.... | 25 | (grs. iv) |
| Destilled Water.....30 | 0 | (℥j). |

Under the influence of this antiseptic the disease rapidly disappears.

### REMOVAL OF BONES FROM THE THROAT.

Dr. O. Schliep (*Wiener Medizinische Presse*, No. 13, 1894) in those cases where a fish-bone or any kind of bone has been swallowed, or is lodged in the throat, removal after cocainization and with the aid of the laryngoscope is impossible, recommends drinking some dilute acid in order to soften the fragment. This suggestion he obtained from the popular employment of vinegar in such cases in Germany. Experiments with vinegar demonstrated that small fish-bones are somewhat softened in fifteen to twenty minutes. Fragments of bone require a longer time, while small scales from shell-fish are softened in one to two hours. Besides vinegar he has also tried 1-5 per cent. solutions of hydrochloric acid, with and without pepsin. Its action is decidedly more energetic than that of vinegar, fragments of lobster's shells only excepted. As hydrochloric acid is a normal constituent of the gastric juice, it rather deserves the preference in rendering fish-bones, etc., non-injurious. It is employed as follows: In case that the bone is situated high up, a stick, around the end of which is rolled a tuft of cotton, is dipped into a 2 per cent. solution (fourteen drops to fifty gms. of water) of hydrochloric acid and repeatedly pressed into the folds of the pharyngeal mucous membrane. In case that it is lower, or if the bone has passed into the stomach, this same solution may be frequently drunk.

### PYOCTANIN INTERNALLY IN MALIGNANT GROWTHS OF INTERNAL ORGANS.

Dr. O. Maibaum (*Wiener Medizinische Presse*, No. 13, 1894) has tried this drug in the treatment of internal neoplasms of a malignant nature, in Prof. Wassliew's clinic in Dorpat, Russia. He administered it three times a day in doses of six cgms.

*In charge of the Translator, F. H. Pritchard, A. M., M. D.

(one grain), in pill form or associated with belladonna as a suppository:

℞

| | | |
|---|---|---|
| Pyoctanin,.....o | 06 | (gr. j). |
| Extr. Belladonna,.....o | 02 | (gr. 1-5). |
| Cocoa Butter,.....2 | o | (grs. xxx). |

In a case of pronounced cancer of the stomach an astonishing result was obtained; the patient increased in weight, the vomiting and eructations ceased and his appetite reappeared. In another case where there were adhesions with the liver and metastases, improvement followed, but the patient soon left the clinic. Also in cases of carcinoma of other organs it was found to be of great service.

---

CALOMEL AS A DIURETIC IN NEPHRITIS.

Drs. Dunin and Sklodowsky (*Wiener Medizinische Presse*, No. 13, 1894) of Warsaw, Poland, claim that the prevailing opinion that calomel, though a valuable, diuretic in heart diseases, is of no value in renal affections, to be unjustified. They have employed it in fourteen cases of acute and chronic parenchymatous nephritis without having seen the slightest trace of a harmful action. Amongst these there were two where caffeine was employed without success, and, in two others, the disappearance of the œdema could only be ascribed to the calomel. In five cases no diuresis followed its administration. It was prescribed in the following formula:

℞

| | | |
|---|---|---|
| Calomel.....o | 20 | (grs. iij). |
| Opium.....o | 01 | (grs. 1-5) |

Sufficient for one powder. Three per diem.

At the same time the patient should use a gargle of the chlorate of potash, and apply the tincture of iodine and nut-galls to the gums. The calomel was administered for three to four days in succession.

---

LARYNGEAL PHTHISIS.

Prof. Cozzolino (*Gazzetta Degli Ospitali*, No. 6, 1894) recommends the insufflation of the following powder in the treatment of laryngeal phthisis:

℞

| | | |
|---|---|---|
| Powdered Iodoform..... 5 | o | (5j¼). |
| Powdered Phosphate Lime. 10 | o | (5ijss). |
| Powdered Boric Acid..... | 40-80 | (grs.vj-xij). |

Insufflate morning and evening, into the larynx.

---

HYSTERIA IN CHILDREN.

Prof. Jules Simon (*La Sperimentale*, No. 5, 1894) in the management of hysteria in children, advises removal from their accustomed surroundings and family, a quiet life, and a tonic treatment. Antispasmodics, on the contrary, are indicated: valerian, belladonna, etc. The bromide of potash does not always give good results. Valerian is best administered in a decoction with 10-15 gms. (ʒiiss ʒiv) of the root in 200 gms. (ʒvjss) of water, reduced to one-half a glassful by boiling. Of the valerianate of ammonia a dessert-spoonful may be taken at ten in the morning and six in the afternoon. Zinc may be also employed in pill form. Opium is to be avoided as it favors constipation and decreases the appetite without restoring intellectual equilibrium. Preparations of belladonna, hyoscyamus, in doses of a cgm. (gr. ⅙) of the extract are useful especially in the visceral pains. Camphor, by rectal injection, may also yield good results. Iron is to be excluded for by attempting to cure the anæmia, one will cause excitement. It would be preferable to administer the sulphate of lime in the food in the summer and cod-liver oil during the winter. Electricity which would seem indicated has not given any decided results. The galvanic current has been frequently employed by him without success; an intense faradic current will only increase nervous excitement. Slight galvanic currents with moderate massage are the best. Nux vomica does not render any useful service; it is not the terminations of the nerves which are diseased, but the will; a temporary abdication. Hence the indications are to excite neither the brain nor the skin, and to employ, together with isolation of the patient, valerian, hyoscyamus, etc. The electric bath is warmly recommended by Sagretti, of Rome, in the hysteria of children. He claims beneficial results.

---

CALOMEL SOAP IN SYPHILIS.

Dr. Watraszewski (*Przeglad Chirurgiczny*, Tom I. Zeszyt II) warmly praises a calomel soap in the treatment of syphilis. It is prepared by carefully mixing calomel with a potash soap in the proportions of 1:2 or 1:3. This soap possesses the important characteristics of mercurial salve and mercurial soap, besides the following additional advantages:

1. It may be employed in inunctions without requiring but very little time for its application—ten to fifteen minutes.
2. It is colorless and does not stain the linen.
3. It will not irritate the skin.

### CHRONIC GONORRHŒA IN THE MALE.

Dr. J. Funk (*Przeclad Chirurgiczny* Tom 1, Zeszyt III) regards chronic urethral catarrh of gonorrhœal origin as chronic gonorrhœa, even though the presence of the gonococcus cannot be demonstrated. In recent gonorrhœa of moderate intensity he recommends oil of sandalwood, with injections of-Ricord's mixture, alternating with injections of nitrate of silver solution (1:4000). In invasion of the anterior and posterior urethra he advises deep injections of a 1-2 per cent. solution every five days. In chronic superficial gonorrhœa of the anterior portion, he commences with an injection of nitrate of silver (1:4000–1:2000) alternating with bismuth (1:1000); in case of failure he applies locally a 2-3-5 per cent. every five days, during the intervals injecting Ricord's formula. In chronic gonorrhœa of the anterior urethra with profound alterations, metallic sounds or sounds coated with Unna's salve are of material benefit. Gonorrhœa of the posterior portion requires deep injections of a 2-3 per cent. solution of nitrate of silver and, in case of prostatic invasion, one should use, besides metallic sounds the cooling sound (Winternitz's), suppositories of the iodide of potash or of ichthyol, with the general treatment.

### SUFFOCATING BRONCHITIS.

Dr. Hutchins (*La Revue Medicale*, March 18, 1894) speaks highly of the bichromate of potash in suffocating bronchitis. He advises the following formula:

℞ Bichromate Potash,.....0 | 05 (gr. ¾)
Sugar Milk,.....0 | 30 (grs. v).
Water, Twenty teaspoonfuls.
Triturate.

According to Dr. Drysdale, of Cannes, the bichromate of potash has an elective affinity for the mucous membrane of the respiratory passages. This solution is generally well borne with the minimum dose of one mgm. (gr. 1/60) for a child of one year, and with oppression and suffocation a maximum dose of three mgms. (gr. 1/22) which may be diminished in case of vomiting. (This dose seems still too large, for being a powerful irritant to the stomach and secondarily to the kidneys, it is liable to cause vomiting and renal irritation.)

### HEMICRANIA.

In the (*Gazzetta Medica di Roma*, No. 5, 1894) the following formula is recommended in the treatment of migraine.

℞ Citrate Caffeine,.....1 | 0 (grs xv).
Phenacetine,.....2 | 0 (grs. xxx).
White Sugar,.....1 | 0 (grs. xv).
Sufficient for ten capsules.
One every three to four hours during the period of the attack.

# CORRESPONDENCE.

## LONDON LETTER.*

March 20th, 1894.

Affairs medical are very lively, just now, in this colossal city; though in a few days, with Good Friday beginning, the Easter holiday season opens, and with many of the principal schools there will be a vacation until the second week in May.

Numerous holidays is a characteristic feature of English life. These numerous breaks in the annual session, with the easy, slow methods of imparting and acquiring knowledge, partly account for the necessity of the present long course of five years before degrees are conferred; the generally conceded purpose or justification being with a view of reducing the output of graduates. There are thirteen medical schools in London, with six large general hospitals and an almost innumerable number of special and minor ones. It appears that the number of matriculants in all the schools is about the same this year as usual; but, it is interesting to note the very small average numbers of students who attend lectures or clinics. The writer, in his tour through most of the schools during session hours and the hospital clinics, in no instance saw more than twenty attend at one time. This paucity of attendance was especially noticeable at the clinics, which, though often held by notable teachers, would seldom have more than

*Special correspondence to THE MEDICAL AND SURGICAL REPORTER.

ten or a dozen present. The ubiquitous "grind" is in steady demand in this city by those delinquents who find themselves behind as the time for graduation approaches. He has a practical method of "cramming" and giving "tips" when the time for examination arrives, so that, with his aid, many may slip through who might otherwise fail.

Here antiseptics yet hold well their own. Operating theatres, as a rule, are well-lighted, heated and ventilated. It is curious to note how largely woolen materials are employed as substitutes for cotton. All bandages are made of wool, and, impregnated or simple, it is used largely instead of gauze in ribbon strips in packing. Wool is abundant and cheap in England, but apart from this it has many highly valuable qualities which render its use preferable to cotton fabrics. It is highly elastic, a good non-conductor, and, when deprived of its oleaginous elements, is highly absorbable. Lister's alembroth has the general preference as an antiseptic dressing. In a general way perhaps one would say that in England as in America, surgeons of the present day are not fully innocent of excessive cutting and of the needless performance of many operations. This complete suppression of sepsis provides a guarantee often liable to carry one to undue lengths and to use the knife when it would be infinitely better to act on conservative lines.

The general practice of operating indiscriminately on every type of non-strangulated hernia has been quite generally abandoned, and now few of those so-called radical cures are undertaken unless complicating elements are present.

There are many reasons why Americans should more generally stop at London for a post-graduate course than cross to any of the continental cities. Here there are shoals of clinical material; victualing and lodging are cheap and good; the language is common and the facilities cannot be easily excelled.

From the present outlook, the attendance from London to the International Congress at Rome will not be large. Teachers and others interested in medical school work find it very difficult to get away. Yet, it is said, that as the meeting occurs in holiday time there may be a much larger delegation from Great Britain and Ireland than would otherwise attend.

The general health of London during the past winter has been unusually good; and to a person going there from America, it would appear odd that any one should ail there who had enough to eat and was comfortably clothed, as the climate is so bracing and regular. But unhappily like all great cities, London has its full share of the destitute poor and dissipated. The average life of an Englishmen should exceed that of an American in similar circumstances, and, as a matter of fact, it does. It certainly strikes one as remarkable to see the very large number of very old men who are actively employed here. It appears that of the 21,528 "bus" and tram car drivers of London, 917 are over seventy years of age. Among the literary walks of life it is not uncommon to see men of eighty or ninety years, hale and hearty. Mr. Gladstone is approaching ninety, and is yet the possessor of an active mind, and the late Duke of Wellington, who lived up to eighty-two years, was said to have enjoyed robust health until the last year of his life.—*Un Voyageur.*

---

## "Doc."

If it has been your misfortune to be called "doc," and if this recognition has become at all general among your friends you might as well move to some other place. A man may be called a thief, a liar and a dead beat, and yet he may prosper and live upon the fat of the land. But once let him be called "doc" and his professional success is at an end. We would prefer to spend a night in the station house, so far as its effect on our professional success is concerned rather than to have our friends notice our approach by saying, "There comes doc." If a man calls you "doc" you need never expect a penny from him for any professional services you could render. His answer is sure to be, "All right, doc, in a few days that will be all right." "Doc" means disaster. "Doc" is the culmination of all calamity. "Doc" is a catastrophe given at one stroke. "Doc" is the warning that we have reached the extreme limit of our usefulness. "Doc" is the hand which points us to the next town. Shun it, my young friend, as you would flee from a Kansas cyclone or a prairie-fire. Knock the man down who first dares speak it to you; and call upon the whole medical profession for vindication of your righteous deed.—*Nat'l Med. Rev.*

# THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address care P. O. Box 843, Philadelphia, Pa.

HAROLD H. KYNETT, A. M., M. D.
Editor

RODERIC C. PENFIELD
Publisher

147-149-151 North Tenth Street, Philadelphia

TERMS:—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 5, 1894.

## EDITORIAL.

### THE REVISED VERSION.

Heretofore, the REPORTER has purposely refrained from commenting upon the question of the revision of the Code of Ethics, because it believes the importance of the subject has been much exaggerated, and because, so far as the great body of the profession is concerned, the discussion is unprofitable, as in the settlement the profession at large has no voice, either directly or through duly authorized representatives. It is the current impression that the Code of Ethics is a system of rules established by, and binding upon the entire medical profession of this country. As a matter of fact it is no such thing. The Code of Ethics is a declaration of the American Medical Association and its provisions are obligatory only upon members of that association and upon such others as may voluntarily yield allegiance to the action of that body. Why its influence has extended so largely over the profession will appear later on.

That magnificent organization called the American Medical Association, is generally regarded as the representative body of the medical profession of North America. And so it is, in the narrow sense that its members are drawn from all parts of the continent and are representative of the *personnel* of the American profession. Strictly speaking, however, it is not representative, for it is not a body of delegates duly authorized and empowered by the profession at large to take any action or formulate any measure, the results of which would be obligatory upon all practitioners. Like any other organization, the Association has the right to make rules and regulations for the government of its own membership, and its action is in honor binding upon all persons holding membership therein. But its power stops short at that point. There are, in round numbers, one hundred and twenty thousand practitioners of medicine in the United States, while the total membership of the American Medical Association does not exceed, if it reaches five per cent. of the entire number. There are

social and physical peculiarities in America, which render impracticable a medical central organization representative in the sense that the British Medical Association is representative of the profession of Great Britain. It is true that a portion of the membership of the American Medical Association is made up of delegates from various medical societies in affiliation with the Association, but if such delegates possess any authority whatsoever to legislate—which they do not—their action could affect only the societies they represented. It would be unwise to assume that the majority of the profession is amenable to the regulations of the various bodies represented in the Association. But in addition to such delegates, a very considerable portion of the membership of the Association is made up of individuals, who, by no stretch of imagination can be considered representative of any save themselves. Thus the American Association, as at present constituted, represents only itself, and consequently can legislate only for itself.

This view of the situation is generally lost sight of in the more or less intense discussions, *pro* and *con*, that are being exploited in current medical journals. Why it so happens, and why the Code of Ethics exercises so strong an influence on practitioners who are not directly subject to its provisions, renders necessary a few words upon the code itself.

What is the Code of Ethics? We venture to say that not twenty-five per cent. of the medical profession can answer the question in detail. We doubt very much if two per cent. of the entire number graduating medicine in 1894, have any satisfactory knowledge of the subject, either from their own study, or from their teachers, or from information gained in any authoritative manner. If asked, most of them would state such an idea of it as they may have, to be, that it forbids, under dire penalties the concession of any virtue to exist in an "irregular," or holding any communication with such an one; forbidding partial or entire ownership in any patented instrument or appliance; the ownership, or use, or endorsement of a secret, or proprietary medicine; or indulgance in personal advertising. Perhaps some might include a few indefinite ideas of formal courtesies that should exist between physicians, but, as a general rule, the conception would be limited to the "shalt not's." On the other hand, those more familiar with the code, depending upon their point of view, may esteem it anything from the straight gate and narrow way leading to a medical Paradise—and few there be that find it—to something analogous to that patriotism which Dr. Johnson defined as "the last refuge of a scoundrel."

But the Code of Ethics is none of these. As it exists to-day it is a moderate, dignified and liberal expression of the best guiding principles drawn from the experiences and opinions of the best men among the profession and for a considerable time, the observance of which principles in daily life tends to conserve the harmony and unity of a body of men working with a common purpose toward a common end to the benefit of humanity. The present discussion of the Code of Ethics is brought about, not so much by a lack of elasticity of the principles of the code itself, as it is by deductions drawn from an inelastic interpretation thereof.

It will be observed that the code does not assume the authority of a statute law. At the farthest it pronounces certain practices, not necessarily immoral in themselves, when brought within the domain of medical practice to become reprehensible and derogatory to the dignity of the profession. But it does not provide any penalty for failure to observe its declarations, which are capable of a much wider interpretation than that almost universally given. When the code was formulated,

not one new principle was enunciated, not one new practice advocated, not one new condition deprecated. Every principle incorporated therein was common to the entire profession; existed before codification was thought of; obtains to-day with little reference to the written code, and will continue in force hereafter, whether or not the code is modified, or whether it exists at all. The code voices the beliefs of the profession; in no sense did it create them, and it does but little to sustain them. So far as morality is concerned, the code is observed by those who do observe it, not because it is *The Code* but because the principles embodied therein are governing principles with the individual; and where the belief and practice of these principles is not characteristic of the individual, the code is utterly powerless. Regarded as an expression of moral law alone, the Code of Ethics sinks into insignificance when compared with its fundamental principle as embodied in the Golden Rule. As a system of morality it is very inferior to the code contained in the Ten Commandments, together with the Golden Rule. It is because the Code of Ethics is an expression of the application to a particular branch of human endeavor, of recognized moral principles which obtain among men and not because it is the dictum of any association of men, that it is so generally regarded as binding upon the entire profession.

No claim is made that the Code of Ethics is essential to the development or progress of medicine as a science. Indeed, a primary condition for the advancement of science is, that it shall be free from artificial and arbitrary restraints.

A Code of Ethics is immaterial so far as the acquirement of a medical education is concerned, and finds no recognition in the medical curriculum.

The Code of Ethics is not regarded as a qualification for admission to the ranks of the profession. In so far as it has any definite influence, that influence is not exerted until a practitioner comes into contact with his fellow practitioners, and it would seem that the only occasions upon which the existence of the code becomes evident, are occasions when one practitioner, becoming dissatisfied with the conduct of another, hunts around for a moral scale with which to determine the obliquity of his neighbor.

There are many among the most enlightened and progressive, whose characters and abilities are glories of the American profession, who resent the idea that the medical profession is peculiarly in need of a written code of ethics. They believe, and are justified in their belief, that physicians require no hard and fast laws to define what is right and what is wrong, or anything more than that unwritten consensus of belief sometimes called public opinion. An incontrovertible proof that the abolition of a written code does not mean the abrogation of all sense of morality, or of courtesy, or of ability, and that the absence of a specified code does not entail a wild plunge into practices and conditions which that code would designate reprehensible, is furnished by the profession of the State of New York. The New York profession declined to permit the American Medical Association to dictate in matters of conscience, and, as in honor bound, withdrew from that association, declaring independence of any *written* code of ethics. No evidence is presented, as yet, that the medical profession of New York is less able, less courteous, less earnest or less effective, than is the profession in any other part of the country. Curiously enough, one can observe a constant stream of men from all parts of North America pouring into the centre of the New York profession for post-graduate study and for a chance to see all that is new and best in modern medical science. This is sufficient answer to those who pro-

claim that the Code of Ethics is the one bar restraining the profession from falling over itself in a mad effort to consult with irregulars, or to patent some device, or to seek notoriety through the public prints. As a matter of fact the controlling principles now in existence would remain undiminished in force if the code were utterly repudiated.

Although the idea of any interference with liberty of conscience is utterly repugnant to the American mind, and although every attempt to make regulations that will in any way curtail the freest exercise of the individual's rights to his own convictions of morality will inevitably fail, we are convinced that the *written* Code of Ethics has been and is of benefit to the medical profession. Undoubtedly it has been much abused. Misuse of the code has sometimes made it appear as an impediment in the progress of medical science, but wherever the code has been charged with obstructing progress or with involving the profession in an absurd position, investigation will show that it has not been by an application of the *principles,* which alone give value to the code, but by the misapplication of narrow and arbitrary constructions of the meaning of declarations, which themselves are second-hand deductions from the general principles premised.

The only value possessed by the Code of Ethics is (to quote the Proem of the Report to the American Medical Association) that of "an ideal code which is the crystallization of the best thought and sentiment of any considerable body of men who have for long periods been associated with a common purpose, with reference to the regulation of their conduct in their relations to one another and to society in general.

"Such a code forms an ideal standard, to the requirements of which each individual should strive to attain—a lamp to the feet of the young and inexperienced—a mirror into which the more mature, glancing, may be able to judge whether or not they are swerving from the paths of rectitude and honor."

But especially is it of value as a guide in questions of professional *etiquette*, for "by due conformity to its requirements the prosecution of affairs is facilitated, friction diminished, misunderstandings obviated and intercourse rendered more agreeable; it cannot be neglected by physicians any more than by other classes of society. The peculiarly delicate and personal character of the relations of physicians to their patients naturally involves conditions which call for especial provision in this respect."

Whatever may be the final action of the American Medical Association—and the Association is a powerful factor in moulding medical public opinion—it should never lose sight of the purpose of its existence, which is to *grow into* an organization of a truth representative of medical science in America. If it is deemed necessary to incorporate a declaration of ethics in the general statements of its purposes, it must make that declaration broad enough to include widely varying interpretations, the extremes of which equally may be held in good faith, and to permit of the free exercise of individual judgment as to right and wrong. It should be a medical republic from citizenship in which ethical faith should be no bar. The moment limits are placed upon the free exercise of individual thought and conviction, and the acceptance of a strict and invariable set of rules of conduct is made a qualification for membership that moment, by its own act, the Association ceases to be truly representative of medical science, in that it debars men who may be in every other way qualified and recognized. Only on the broadest possible platform can the American Medical Association achieve the purpose of its organization—a truly representative body of a united profession.

# ABSTRACTS.

## PERMANGANATE OF POTASSIUM AS AN ANTIDOTE FOR MORPHINE.

Dr. William Moor, (*N. Y. Med. Rec.*) writes: In offering to the profession a new intidote for morphine it is not my desire to speak of a new, heretofore unknown or unused chemical body; on the contrary, the substance which forms the subject of these lines is one with which every physician and pharmacist is familiar. The term "new antidote" simply relates to the fact that the substance in question had not previously been used for the purpose of antagonizing or, rather, destroying morphine, for I don't know of a single instance in which permanganate of potassium—$Mn_2O_8K_2$—has been used as an antidote for morphine.

I have paid a good deal of attention to the therapeutics of permanganate of potassium during the past year, thinking that such a powerful destroyer of organic matter should be more utilized in the treatment of certain gastric disorders that are associated with putrid fermentation of the ingesta, also in cases of cancer of the stomach to suppress the fœtor of the breath, which renders patients a burden to their surroundings, and came to the conclusion that its mode of administration was at fault, inasmuch as no one likes to drink a purple, "poisonous" looking liquid, and, on the other hand, if given in pill form, it would act as a caustic upon a very small part of the glandular lining of the stomach, thus causing distress without any beneficial result. After some trials I found that the best way of administering it was to have it made up in pills with cacao butter and talcum or kaolin, and to direct the patient to drink very slowly a glassful of water just one minute after taking the pill, for the latter begins to disintegrate in one minute at the temperature of the body. By using this method I successfully combated the extremely disagreeable odor in a case of cancer of the stomach. About that time I treated a well-known actor suffering from acute pleurisy. This gentleman was addicted to morphine, and as I had taken much interest in him, I earnestly sought the best plan to break his habit. The idea occurred to me that perhaps permanganate of potash might decompose morphine, the latter being an organic substance, and that by making use of a certain method I could eventually break this habit without restricting him from taking his morphine. My patient, however, started on a professional tour just when I began to put my idea to a test. This circumstance did not prevent me from continuing my researches as to the effect of permanganate of potassium on morphine, and to-day I am permitted to offer to the profession what I consider to be the antidote *par excellence* for morphine.

In the following remarks I shall give a brief outline of the experiments that led me to this conviction. Pouring a solution of one grain (0.06 gramme) of $Mn_2O_8K_2$ to one ounce of water (31 c.c.) into a solution of one grain of sulphate of morphine to one ounce of water, I noticed that this mixture did not for an instant assume the purple color of a $Mn_2O_8K_2$ solution, but at once formed a greenish liquid; and that after a few moments a dark precipitate would sink to the bottom of the test tube, leaving an almost colorless, tasteless liquid, in which the presence of morphine could not be detected. Knowing my great susceptibility to even very small doses of morphine, I could easily ascertain whether or not this colorless, tasteless liquid possessed any narcotic qualities. The road of safety being the best way, I began by taking a mixture of one-sixth of a grain of sulphate of morphine and one ounce of a 1 to 2000 $Mn_2O_8K_2$ solution. Under ordinary circumstances one-sixth of a grain of morphine has a profound narcotic effect on me, lasting for several hours; I, therefore, rarely have taken for analgesic purposes more than one-eighth of a grain. The above-mentioned mixture of one-sixth of a grain of sulphate of morphine and one ounce of a 1 to 2000 $Mn_2O_8K_2$ solution produced no effect whatever on me. Gradually I increased the amount of morphine, and correspondingly the amount of permanganate of potassium, until I took two grains of the sulphate of morphine in one dose with the same amount of permanganate of potassium in solution. The

results of these experiments, however, did not demonstrate that permanganate of potassium was an antidote to morphine, as it was quite possible that it might be deoxidized by the organic matter of the buccal cavity, œsophagus, and stomach, chiefly by the contents of the stomach, before it could act on the morphine. To gain certitude on this point I conducted a series of experiments, a synopsis of which is as follows:

1. A 1 to 2000 solution of permanganate of potassium in water was held in the mouth for fully five minutes, when it still had a dark-red appearance, approaching the characteristic deep purple color of a $Mn_2O_8K_2$ solution, although the tongue and the gums have become brown.

2. If we dissolve one drachm (4 c.c.) of the white of egg in one ounce (31 c.c.) of water, and to this add one drachm of a 1 to 250 solution of permanganate of potassium in water (one-fourth grain of $Mn_2O_8K_2$) the mixture will for a moment have a purplish color, and after stirring it for one minute will be of a reddish-brown color, and have a distinct taste of permanganate of potassium. After five minutes, on filling two test-tubes with this mixture and adding to one of them a small quantity of sulphate of morphine—this latter being an energetic deoxidizer of $Mn_2O_8K_2$—but adding nothing to the mixture in the other test-tube, the former mixture will at once become of a much lighter color (light amber) than the one without morphine. Even after thirty minutes this differentiation can be affected. Thus we see that it takes one drachm of the white of an egg at least thirty minutes to completely deoxidize one quarter of a grain of the permanganate. Now, I found that one quarter of a grain of permanganate will be deoxidized by exactly the same amount of sulphate of morphine in one second—for the sake of convenient calculation one moment may be considered as one second—therefore one drachm of sulphate of morphine deoxidizes one quarter of a grain of the permanganate at least seventy-two thousand times quicker than a drachm of albumen would do it, assuming that the latter could accomplish it in five minutes. But as we saw that the deoxidization was not complete after the elapse of half an hour, we are justified in saying that the chemical reaction between the permanganate and the salt of morphine is infinitely more rapid than the one between the former and the white of egg.

3. By substituting for the albumen one drachm of peptone, in the experiment just related, we find that one grain of $Mn_2O_8K_2$ is not completely deoxidized by one drachm of peptone in five minutes. Calculating in the same manner as before we come to the conclusion that the rapidity of reaction between the permanganate and the salt of morphine is at least eighteen thousand times greater than the one between the former and peptone.

Having gained the knowledge of these facts it is not surprising that I could swallow with impunity toxic doses of sulphate of morphine followed in a few moments by a corresponding amount of the chemical body which I was justified to consider the antidote *par excellence* for morphine. Thus, on one occasion, four hours after a full dinner, at a time when the stomach must have contained a great amount of soluble peptones and other organic matter, I took two grains of the sulphate of morphine in about half an ounce of water, followed in one minute by three grains of its antidote—for safety's sake one grain more than necessary—dissolved in four ounces of water. In another instance, on January 9th of this year, three hours after a light supper, I took, in the presence of several colleagues belonging to the staff of the West Side German Clinic of this city, three grains of sulphate of morphine, followed in about thirty seconds by four grains of permanganate of potassium, both in aqueous solution. I was perfectly confident that the antidote possessed such a wonderful affinity for the morphine that it would select it instantaneously from among the contents of the stomach, and thus render harmless what might have easily been a fatal quantity to one so susceptible as I am to even very small doses of this alkaloid. A striking demonstration of the astonishing selective faculty of $Mn_2O_8K_2$ for morphine can be shown by mixing two hundred and fifty grains of the white of egg with one ounce of water, dissolving in this mixture one grain of sulphate of morphine and adding to the whole just one grain of the permanganate dissolved in one ounce of water. After thoroughly mixing not a trace of morphine can be detected; which conclusively proves that the molecules of the antidote instantaneously selected the molecules of morphine

without being interfered with by the albumen, though the quantity of the latter so greatly exceeded the quantity of morphine.

The question arises, What becomes of $Mn_2O_8K_2$ and $C_{17}H_{19}NO_3+H_2O$ (morphine) after they have reacted upon each other? While it is easy to determine that the permanganate is deoxidized by the morphine with formation of manganese binoxide—$MnO_2$—manganate of potassium—$MnKO_4$—and potassium hydroxide—KHO—thus leaving $O_2$ for the oxidation of morphine, this latter undergoes changes, the nature of which I have not yet been able to determine, but hope to be able to do so in the near future.

In case of poisoning by any of the salts of morphia, ten or fifteen grains of the antidote dissolved in six or eight ounces of water should be administered at once and repeated at intervals of thirty minutes three or four times, or even more often. Permanganate of potassium, as well as the salts of manganese, are comparatively harmless even if given in large quantities. I have poured into the stomach of a rabbit weighing four pounds a solution of five grains of $Mn_2O_8K_2$ in two ounces of water, and one hour later two grains more dissolved in one ounce of water, without noticing any toxic effects whatever. One ounce of the sulphate of manganous oxide has caused only brisk catharsis (Dr. Thompson).

In cases of poisoning by the alkaloid itself or by tincture of opium (laudanum), also by opium, it is advisable to acidulate the antidotal solution with diluted sulphuric acid, or in the absence of this with some white vinegar (not red vinegar), by which the insoluble morphia will be at once converted into the soluble sulphate or acetate.

I have strong reason to believe that the administration of permanganate will be of beneficial effect even after absorption of the morphine has taken place. This statement I base on the following:

Professor Edward Hitzig,* of Halle, two years ago, proved beyond a doubt that morphine which was injected subcutaneously into dogs was secreted by the glandular lining of the stomach. Hitzig succeeded, by washing out the stomachs of animals that had received morphine subcutaneously, in obtaining fully one-half of the injected amount during the first hour after the injection. It is therefore a logical necessity that an antidote which acts instantaneously must destroy in the stomach a certain amount of poison that got into the circulation either through hypodermatic injection or through absorption by the stomach, for it is evident that the same circulation which conveys a poison from the peripheral parts of the body to the stomach, must also bring back to the latter a part of the poison which previously was absorbed by it. I intend to carry out a series of experiments upon animals to prove this conclusion; for the present I just state that some experiments for this purpose upon rabbits have been highly encouraging. As to the effect of permanganate of potassium upon other alkaloids, I shall briefly enumerate the results I have obtained.

*Atropine.*—One grain of sulphate of atropine dissolved in one ounce of water added to one grain of permanganate of potassium in half an ounce of water. Color, purple, as if the solution contained only permanganate of potassium. After four hours, color still purple, no change from original permanganate color; one drop instilled into a person's eyes widely dilates the pupils in a few moments; midriasis lasting over twenty-four hours. After eight hours, color dark red, taste intensely bitter; addition of sulphate of morphine gives the characteristic reaction (dark precipitate, colorless liquid above it). After twenty hours, color dark brown, taste intensely bitter; addition of morphine gives the characteristic reaction. Thus permanganate of potassium has practically no effect upon atropine.

*Cocaine.*—One grain of cocaine muriat. to one ounce of water added to one grain of permanganate of potassium in half an ounce of water. Color, purple, as if the solution contained only $Mn_2O_8K_2$.

Four hours later, color dark red, taste intensely bitter; one drop instilled into a person's eye causes decided midriasis lasting half an hour; addition of morphine gives the characteristic reaction. Eight hours later, color grayish red, taste bitter; applied to the pharynx distinct difficulty in swallowing noticeable; dark precipitate on the addition of morphine.

Practically no effect on cocaine.

*Veratrine.*—Two grains of veratrine muriat. to half an ounce of water added

*Berliner Klinische Wochenschrift*, No. 49, 1892.

to two grains of permanganate of potassium in one ounce of water. Color, purple. Ten minutes later, purplish red. Fifteen minutes later, dark brown; precipitate on addition of acetate of morphine. Thirty-five minutes later, precipitate with brownish liquid above, the latter turning light on the addition of acetate of morphine, and if applied to the nasal mucous membrane causing violent sneezing (one of the characteristics of veratrine). Useless in veratrine poisoning.

*Pilocarpine.*—Two grains of pilocarpine muriat. to two ounces of water added to two grains of permanganate of potassium in one ounce of water. Color, purple; after five minutes, still purple; after forty minutes, carmine.

After seventy minutes, color carmine; one drachm injected subcutaneously into a rabbit causes lachrymation, salivation, profuse perspiration, irregular, rapid breathing (160), three or four copious watery discharges.

After three hours, color still red; addition of morphine gives the usual reaction. Practically without effect on pilocarpine.

*Aconitia.*—Two grains of aconitine to two ounces of water + two grains of permanganate of potassium to one ounce of water. Color, purple. After stirring for two minutes, same color.

After two hours, color unchanged; half a drachm (2 c. c.) injected into a full-grown rabbit; animal restless in a few moments, turns his head to the side, makes rapid swallowing motions, salivates, is evidently nauseated; difficult, irregular breathing, tremor, opisthotonos; animal lies on its side, apparently *in extremis*, but after ninety minutes symptoms begin to abate.

After twenty-four hours, color still reddish purple. Dark precipitate by addition of morphine. No effect on aconitine.

*Strychnine.*—One grain of strychn. sulphat. to one ounce of water + one grain of permanganate of potassium to half an ounce of water. Color, purple; after five minutes, red; after fifteen minutes, dark brown, intensely bitter; after thirty minutes, same color, taste intensely bitter. Addition of morphine, black precipitate, colorless liquid above.

Could not be depended upon in strychnine poisoning, if the stomach should contain organic matter, which is the rule.

I now submit this paper to the unprejudiced criticism of the profession, and hope that my *confrères* will aid me in developing the ideas laid down in it. If my humble efforts should result in saving human lives, I should feel amply rewarded.

### Headache.

℞ Caffeini Citrat. } āā ʒi.
Ammon. Carb. }
Elix. Guaranæ ʒi.

M. Sig. Teaspoonful every hour until relieved.

—*Exchange.*

### For Dysmenorrhœa.

In ovarian neuralgia and dysmenorrhœa where opiates cannot be tolerated, the following will be found useful:

℞ Ext. Belladonnæ gr. 1·5
Ext. Stramonii gr. 1·5
Ext. Hyoscyami gr 1·4
Quinine Sulphatis gr. 1·2

Mft. pil. No. 1.

—*Steer.*

### Sciatica.

Sciatica and other neuralgias:

℞ Tinct. Aconit }
Tinct. Colch. Sem. }
Tinct. Bel. } āā equal parts.
Tinct. Actea Racem. }

S. Six drops every six hours.

—*Metcalf.*

### Hay Fever.

Dr. T. F. Sterling uses:

℞ Eucalyptol ʒi.
Glycerini ʒi.
Tinc. Opii ʒii.
Aq. Dist. q. s. ad ʒvi.

M. Sig. Use with atomizer three or four times a day. The complaint will be overcome in a few days.

### Fetid Diarrhœa in Children.

Dr. E. Tompkins (*La Semaine Medicale*) speaks highly of the following, in the fetid diarrhœa of children as an intestinal antiseptica:

℞ Calomel 10 cgms (grs. jss).
Sulpho-Carbonate of Zinc 15 " (grs. ijss).
Subnitrate of Bismuth 8 gms (ʒij).
Pepsin 2 " (grs. xxx).

Sufficient for twelve powders. Three per diem in a child of one year.

### For Bronchitis.

℞ Spts. Terebinthinæ ʒiij.
Acid Acet ʒiv.
Vitelli Ovi one
Aquæ Rosæ ʒiiss.
Ol. Limonis ʒj.

M. Sig. Apply morning and evening.

Aitkin extols this liniment very highly in bronchial diseases.

## FRAUDULENT MEDICAL INSTITUTIONS.*

Of the twenty-one more or less active diploma "mills" still in existence in the United States, as described in the Report on Medical Education, by the Illinois State Board of Health, the following are among the most noteworthy:

"*Chicago Correspondence University*," Chicago, Ill. Incorporated in 1885; re-incorporated in 1887. "*National University of Illinois*," Chicago, Ill. Incorporated July 25, 1889. These two institutions, incorporated by the same person, have had no existence as teaching bodies for purposes of medical instruction, but are operated solely for the sale of their so-called "diplomas." A "diploma" of this "National University," signed "F. W. HARKINS, Præses," and issued to THOMAS J. REDMOND, "*datum pridie Januarias, Anno Domini*, MDCCCLXXXIV," was offered for record by the said REDMOND in Logan County, Idaho, May 14, 1891. The discrepancy between the date of incorporation, 1889, and the date of the "diploma," 1884, has not been explained.

In September, 1892, the secretary of the "University," one RUDOLPH A. VAN ANGELBECK, "Lit. D. F. N. U.," wrote from Pella, Iowa, offering the degree of M. D. to a graduate of the Chicago Ophthalmic College. The following is an extract from VAN ANGELBECK'S second letter: "In case you are afraid your diplomas do not entitle you to the M. D. degree, apply at once for a Fellowship, remitting $30 for same. Our Fellowships entitle holders to *any* degree." VAN ANGELBECK was arrested and indicted in March, 1893, for misusing the United States mails in carrying on his sale of the degrees of the "National University."

In November, 1892, the HON. JOHN W. FOSTER, Secretary of State, forwarded the complaint of the Department of Justice of the city of Amsterdam, Netherlands, showing that "this 'National University of Illinois,' at Chicago, has been selling medical diplomas to foreigners who have not taken its courses." One "PROF. BLACKBURN, M. A., D.Sc., LL.D.," was the agent for sale in London, England,—"price, two guineas."

During 1893 it transpired that these "diplomas" were being peddled under representations leading to the belief that they were from the new University of Chicago. DR. GOODSPEED, Secretary of the Chicago University, has no doubt that the University is being injured by HARKINS and his "diploma mills," and "would like to see the matter thoroughly exposed everywhere, particularly in England and Canada."

"*Malok's Brood*."—During the past three years one JOHANN MALOK, of Chicago, has profited by the wide-open incorporation laws of Illinois to the extent of securing charters for a brood of fraudulent diploma-selling institutions ostensibly formed—according to the language of their articles of incorporation—"To instruct students in medicine and surgery and to give diplomas to graduates;" "to educate pupils in medical science, to graduate them and to issue degrees of M. D., and honorary degrees of M. D., and to issue diplomas as graduates of obstetrics for accoucheurs and midwives;" "to educate people in all branches pertaining to medical science and obstetrics, dentistry, hydrotherapeutics, magnetism, hypnotism, and in everything that is for the benefit of the human body; and to graduate in the same and to issue diplomas and all kinds of degrees and honorary degrees for the same in present or absent." This last quotation is the "enlarged object of the German Medical College," chartered by the State of Illinois, December 28, 1891, certificate of "enlargement" filed by the Secretary of State, July 14, 1892.

The first formed of the Malok brood was the "German College of Medicine and Obstetrics," charter granted February 19, 1891. Then the "German Homœopathic Medical College," charter granted December 8, 1891. Then the "German Medical College," charter granted December 28, 1891; and the "German-American Homœopathic Medical College," the "German College of Gynecology, Pædology and Obstetrics," the "German Academy of Physiatric Physicians," etc. These institutions have been repeatedly and publicly denounced as fraudulent by the Illinois State Board of Health and their so-called "diplomas" refused recognition. Nevertheless, they are legally incorporated under the laws of the State of Illinois.

[* Compiled for the *Journal of the American Medical Association*.]

Evidence of the sale of the Malok "diplomas" in Germany and elsewhere is being accumulated with the view of securing a repeal of these charters.

"*Indiana College of Medicine and Midwifery*," Indianapolis, Ind. Chartered in 1878 by one CHARLES P. HEIL, who, at the time the Illinois Medical Practice Act went into effect, was at the head of the "Northwestern College of Midwifery," in Chicago. His "college" was refused recognition, and he, himself, was denied a certificate by the State Board of Health. Being thus compelled to leave Illinois he removed to Indianapolis, where he started his "Indiana College of Medicine and Midwifery," attention to which was first called by PROF. AUSTIN FLINT, of the Bellevue, in a letter to the Secretary of the Illinois Board, April 9, 1890.

DR. FLINT inclosed a diploma of HEIL'S institution, issued March 12, 1890, and conferring the "degree of Doctor of Medicine and Midwifery" upon one ALEXANDER KUNTSLICH, by whom the diploma was presented to DR. FLINT for registration under the laws of the State of New York. Certificates of the institution were presented to the Illinois Board by midwife graduates, but were refused recognition, and HEIL'S subsequent career may be found under the title, "Ohio College of Obstetrics, Medicine and Midwifery" —*q. v. infra.*

HEIL also announced his Indianapolis institution as the "Department of Obstetrics, Indiana Eclectic Medical College," a college not recognized by the Illinois State Board of Health.

"*Ohio College of Obstetrics, Medicine and Midwifery*," Cincinnati, Ohio. This institution was originally located at Indianapolis, Ind., see "Indiana College of Medicine and Midwifery," *supra.* In 1889 HEIL, the projector, obtained a charter under the laws of the State of Ohio, and began operations in the city of Cincinnati. In 1891 he was reported in the *Medical and Surgical Register* of the United States as living in Covington, Ky., "Dean of the Faculty of the Ohio College of Obstetrics, Medicine and Midwifery, Cincinnati, Ohio." The so-called "College" never had a local habitation or existence—a name only, under which to issue diplomas.

After leaving Illinois, HEIL was "graduated" upon one term of lectures by the Eclectic Medical College of Indiana, an institution not recognized by the Illinois State Board of Health. He appears in the current *Medical and Surgical Register* of the United States in capital letters as:

"HEIL, CHARLES P., A.M., Ph.D., (Ecl.), Ind. Ecl. Med. Coll., Indianapolis, Ind., 1883; Late Prof. of Obstetrics in Ind. Ecl. Med. Coll.; Surg-Steward in the U. S. Navy and Hospital Steward U. S. Army, Late War; Mem. of National and Ind. State Ecl. Med. Assn's; Examining Surg., The Brotherhood of Railroad Trainmen; Late Dean of the Ind. Coll. of Med. and Midwifery, Indianapolis, 1696 3d av., New York, N. Y."

"*Vermont Medical College—the Second Medical College of the American Health Society*," Rutland, Vt. This institution has no existence in Rutland, Vt., except on Commencement day, when one GEORGE DUTTON, of Boston, Mass., who comprises the "Dean and Faculty" of the concern, takes his "graduating class" from Boston to Rutland and there holds "graduating exercises" and issues his diplomas.

DUTTON first attempted to organize what he styled the "First American College of the American Health Society," in Boston; but the Massachusetts Act of 1883, forbidding corporations created under the general incorporation laws from conferring degrees in medicine, secured through the exposure by the Illinois State Board of Health of certain bogus "diploma mills" in Boston, frustrated this attempt. He then incorporated this "Second Medical College" at Rutland, in 1883, under a Vermont act authorizing the creation of corporations to establish and maintain literary and scientific institutions.

Although his "diplomas" are issued in Vermont they do not entitle their possessors to practice in that State, the Supreme Court having decided, in the case of one of DUTTON'S "graduates" against the State Board of Censors, that such institutions are not empowered to confer degrees or issue diplomas. DUTTON gives "instruction" in Boston, and has issued some forty-five or fifty Vermont "diplomas" on which persons are practicing medicine in States which recognize "diplomas or licenses from legally chartered medical institutions."

---

FOGG—Come, Figg, have a smoke.

Figg—I'll die first.

Fogg—Oh, well, every man to his liking. I'll do my smoking before I die.—*Boston Transcript.*

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D.

THE VIRGINIA MEDICAL MONTHLY for April. Dr. J. W. Long contributes a paper on

**Hysterectomy for Fibrous Tumor, Complicated with Pregnancy,**

reporting a successful case. After reviewing the dangers of pregnancy in a uterus which is the site of a fibroid tumor, the author presents the following propositions:

1. Never fail to advise a woman, the subject of a fibroid, of the dangers of pregnancy.
2. Cervical fibroids, whether submucous or interstitial, should always be enucleated if within reach.
3. Subserous fibroids that have small pedicles may be let alone—trusting that they will be pushed aside, and will not take on such rapid growth.
4. Small or medium-sized tumors, that show no special disposition to rapid growth, may be let alone.
5. Large tumors, especially when multiple or interstitial, demand operative interference.
6. Abortion or induced labor are hardly justifiable.
7. Cæsarean section is rarely indicated because of the high mortality.
8. Myomectomy may be practiced in some instances, when there is only one large tumor, and it is situated on the fundus and does not have too broad an attachment to the uterus.
9. When the tumor has a broad attachment, or is situated near the tubes, supravaginal hysterectomy is indicated.

In the instance reported by the author, the woman, a negress, was about three months pregnant. At the operation the ovarian and uterine arteries were ligated and cut, and without any pedicle ligature the tumor was cut away at the internal os. The pedicle was trimmed, the canal cauterized with carbolic acid, superimposed plains of silk sutures applied, and the stump dropped. The peritoneum was carefully sutured on either side, the pelvic cavity made thoroughly dry with sponges, and the abdominal wound closed without drainage. The patient recovered without the slightest drawback. The author states that unless some one else can produce a case ante-dating his (December 26, 1893), he may claim to be the first surgeon in the South who deliberately did a hysterectomy for fibrous tumor complicated with pregnancy. And, possibly, the first one in America to suture and drop the pedicle.

In this issue appear two papers on puerperal eclampsia. The first is from the pen of Dr. W. P. C. Hazen, entitled

**Observations on Puerperal Eclampsia**

with the history of a case. After reviewing the opinions of the various authorities as to the causation, he comes to the conclusion that it is caused by uræmia produced; first, by the pressure of the gravid uterus on the abdominal aorta, its primary branches and the inferior vena cava; second, obstruction to the outflow of urine; and third, the additional burden imposed upon the kidneys, through their excretion of urea, from the fœtus.

In regard to the treatment he states that it is his opinion that in all obstetrical cases in which the physician is consulted, be it early or late in the period of pregnancy, if his slightest suspicion is aroused in regard to the action of the kidneys, he should lose no time in examining the urine. Should we discover albumin, prophylactic treatment is our first thought.

In this line, the very best effects have resulted from the enforcement of a strict milk diet. In those cases in which it is impossible, the diet should, at least, be restricted; in short, the same dietetic treatment is indicated as in true Bright's disease. The physician should see to it that no pressure results from the clothing, and in all cases corsets should be thrown aside. Where it is practicable, in cases of primaparæ, the medical adviser should explain to the husband the ill effects of excessive venery. As to medicinal treatment for prophylaxis, diuretics and saline cathartics hold the first place. Simple bi-tartrate of potash, or a mixture of the bi-tartrate of potash, and infusion of digitalis, make the most valuable diuretics that he knows of for these cases. The tincture of the chloride of iron should be kept up continuously and in generous doses. During the period of prophylactic treatment, special attention should be given to the stomach, and attacks of indigestion should be promptly dealt with.

If nervous symptoms develop, active measures should at once be resorted to. To relieve the severe cerebral symptoms which precede convulsions, and to ward off the convulsions, venesection is undoubtedly the surest and quickest means. He has also used, with good results, elaterium, croton oil and pilocarpine. Hypodermic injections of morphine, in conjunction with any of the above remedies, afford good results.

In regard to the premature emptying of the uterus, he thinks that in certain cases it is undoubtedly justifyable; but his own practice in this respect is the conservative one, of letting nature take her course Labor is generally precipitated by the convulsions; the uterus emptying itself spontaneously.

The second paper on the subject is by Dr. Ralph Davis, "Twenty Years' Experience with Tincture of Veratrum Viride in the Treatment of Puerperal Convulsions." The author administers the drug in doses of twenty-five to thirty drops hypodermically, and claims that it will control puerperal convulsions, when administered in large doses, and that it is perfectly safe to administer it in sufficient quantities to control any case of convulsions. His experience with it has convinced him that it is both safe and efficient. He has used tincture of veratrum viride in

the treatment of every form of conclusion, except traumatic tetanic convulsions.

Dr. Johnson Eliot contributes a paper on

**Foreign Bodies in the Upper Air-Passages.**

Under ordinary circumstance, he says, foreign bodies in the upper air-passages are arrested in well-recognized localities, among which are the pyriform sinus or fossa, situated laterally to the larynx and the sulcus between the tongue and epiglottis. Usually no trouble is encountered, but an epiglottis which lies close to the tongue or has a wide rolling crest, may have to be forced back before a clear view is obtained.

When lodged in the larynx, the body is easy of recognition by reflected light—arresting spasm by chloroform; a solution of cocaine hydrochlorate is also useful. In some cases, a view is obtained of the trachea to its bifurcation, and in one of his cases a considerable portion of the right bronchus was seen. The recesses about the palatine folds, the post-nasal fossa, and the tonsils, also afford places of lodgment of foreign bodies, but here, with manipulation, they are easily seen.

There is scarcely a point in the throat or nose which cannot be viewed, and any adventitious substance removed.

The author does not look with favor on the practice of swallowing large quantities of bread, potatoes and substances forming a large bolus, as he believes by so doing the point of the pin or bone swallowed is likely to be forced deeper into the tissues.

Dr. A. R. Shands discusses

**Tubercular Osteitis of the Hip-joint,**

presenting an analysis of 158 cases illustrating its three stages. Hip-disease, especially in children, follows a distinct type, which is to-day classed as a degenerative tubercular osteitis. It presents itself in whatever joint it appears in much the same form, affecting the spongy tissue of the epiphyses, most often near the line of junction with the shaft. It may begin as a single or multiple focus of tubercular degeneration. Later in the history of the affection, the nodule breaks down into pus; generally, the original focus is surrounded by smaller tubercles, which aid in its extension, but the chief mischief is done by the rarefying osteitis. At this stage of the diseased process the focus may be absorbed, and so cured; it may extend to the periphery of the bone and break through and empty itself there; or it may extend into the joint, by far most common, and infect that. When the diseased focus is not absorbed, the most favorable course is for it to break through the periosteum and discharge into the periarticular structures.

In regard to prognosis, he states that the large majority of cases tend, under favorable circumstances, to recovery with more or less deformity; hence it becomes the surgeon's duty to see that the chances of recovery are as favorable as possible, to use the best means of preventing the deformity, and, at the same to get the most useful limb.

As to treatment, the indications are to furnish fixation, extension and protection; to benefit the patient's health in every possible way; to prevent and correct deformity, and to meet such complications as may arise. For the purpose of fixation, the writer prefers the plaster-of-Paris spica to anything that he has ever seen used. In applying it two assistants are necessary to keep up gentle traction on the diseased limb while the dressing and plaster bandages are being applied, which should extend from the lower border of the axilla to the tips of the toes; traction should be kept up until the plaster is well set. If the dressings and plaster are snugly applied around the processes of the ilium, the condyles of the femur and the malleoli and foot, no motion is possible at any of the joints of the encased limb. The spica should be reinforced by pieces of light steel extending from the free ribs to middle third of femur. If there is more deformity than can be overcome by gentle traction at first sitting, put the limb up in line of deformity after being partially corrected. Within a short time the muscular spasm will be sufficiently overcome to allow the limb to be brought into proper position, when a second spica can be applied. The complete immobilization thus secured will in large majority of cases overcome in two or three months the muscular spasm, sufficiently to admit of the application of the long traction splint. The walking brace should not be applied until the muscular spasm has been sufficiently overcome to reduce the deformity, so that when the patient walks the traction exerted on the leg by the brace shall be in the line of deformity. It should be continued just as long as there is any spasm remaining and until all signs of disease have disappeared.

In regard to the treatment of abscess, the author advises to let it alone if it is not causing constitutional disturbance. If the abscess is increasing rapidly and there is danger of its burrowing into the tissues, aspirate it, then strap it with basket strapping and a roller bandage over it. In regard to excision, he regards it as only justified as a *dernier resort* in the early stage and only when there is reason to think that there is more extensive osteitis than nature can relieve itself of without risk of a fatal complication arising during a long-continued suppuration that will necessarily follow. The author urges the importance of making an early diagnosis; of improving the patient's health in every possible way; of protecting the joint by mechanical means just as soon as spasm is recognized and continuing it just as long as any spasm remains; then he believes very few abscesses will result and rarely ever will there be any necessity for an excision.

Dr. James D. Morgan presents some "Remarks on Typhoid Fever." He believes that calomel, judiciously managed in the prodrome and the first days of the stage of pyrexia, has a salutary effect in shortening the duration of the disease. He has seen good effects from veratrum viride when cold sponging had little quieting effect.

Dr. Joseph Jones presents a

**Contribution to the Natural History and Treatment of Diphtheria**

in the United States, and more especially in

New Orleans, Louisiana. He closes his paper with the following report of the committee of the American Medical Association, made twenty-eight years ago, which he sees no reason to differ from even now.

*1. That diphtheria has occurred as an epidemic from time to time from the first settlement of this country.*

*2. That it is a distinct disease, on no account to be confounded with scarlatina or croup.*

*3. That it is particularly a disease of childhood, although it exempts no age.*

*4. That it is communicable to that degree that it is the duty of every physician to separate the infected from those that are well, particularly in children.*

*5. That it is a disease primarily affecting the blood; consequently the treatment to be effective must be local and general, and of such a nature as to eradicate or neutralize the poison; such local treatment should, however, be used as will prevent the absorption of the fluid portions of the exudation.*

*6. When the exudation has invaded the trachea, the only hope of saving the patient is tracheotomy*

Dr. John F. Moran discusses the "Antagonism of Erysipelas in Disease." The antagonism is due, in his opinion, to the antitoxine secreted by the bacteria.

The remaining papers in this issue are: "Need of Care in the Diagnosis of Spitting Blood," by James D. Morgan, M. D., and a clinical report of a case of "Induction of Premature Labor in Contracted Pelvis," by E. S. McKean, M. D.

---

THE SANITARIAN

for April contains an article by Dr. A. Walter Sinter, on

**State Sanitation,**

particularly in regard to diphtheria and its diagnosis. The author writes of the Klebs-Loeffler bacillus, and the fact that no case can be declared true diphtheria if this bacillus has not been found in the secretions from the lesions. The physician usually cannot promptly examine, bacteriologically, the membrane found in the throat of a patient, and as it is of great importance to the community that this should be done by some one, the various boards of health should arrange laboratories to have all cultures submitted to them by physicians, examined at once, and should notify physicians to make, and promptly submit these cultures.

In New York the system has been put in practice, and the only obstacle now is the very small appropriation given the Board of Health to carry out its work.

In the same number an article from *Engineering* refers to "Dangerous Occupations," and those involving the handling of carbonate of lead particularly.

Means for rendering these less dangerous to the workman are pointed out, and also the fact that as it would involve some extra trouble, and even a little discomfort for the workers, they stand opposed to measures intended solely for their benefit, and the workers prevent the improvements more than the employers, who would feel the changes suggested very decidedly in the greater expenditures made necessary.

Dr. William Paul Gerhard writes about the

**Modern Rain-Bath.**

The article refers to the shower-bath, compared to the tub-bath, in schools, factories, barracks, etc.

Where many persons are to use the same apparatus it is important that it shall work rapidly, effectively, take up as little room as possible, and consume as small a quantity of warm water as possible.

These objects seem to be gained by the use of the inclined shower, in preference to the ordinary tub. Figures are given to show the relative amounts of water, etc., required, and the author claims that the bath has the additional advantage of toning the system instead of leaving the bather in a languid condition, as a warm tub-bath usually does.

---

THE BRITISH JOURNAL OF DERMATOLOGY

for March. Dr. Stephen Mackenzie writes about

**Urticaria,**

which he believes to be due to some irritation of the nervous plexuses supplying the skin caused either by some poison absorbed, as in the case of ruptured hydatid cysts, or by some poisonous food, as mussels. Or it may be reflex as seen in some cases of gastritis.

Several cases are detailed showing the different appearances urticaria may present in different persons.—Urticaria hemorrhagica, presenting large patches resembling bruises, and a dark band encircling the abdomen, while at the same time wheals were to be seen on the extremities—this case, the author thinks, a manifestation of hemorrhagic diathesis, and not a distinct form of urticaria. Another case was mentioned where a patient had suffered, in spite of treatment, from urticaria of ten or twelve years standing. In a case of urticaria pigmentosa, patches of buff colored skin were found over various parts of the body, and these became so irritable, on exposure to the air, that the patient began rubbing and scratching, causing the appearance of wheals, papules, etc.

Giant urticaria is another division, and under this head is mentioned a case where the eruption was so great, and also occupied so much space, that a diagnosis of erysipelas was made—the slight constitutional affection, and the short time it lasted, and the presence of more characteristic spots elsewhere, made the diagnosis plain.

The opinion of Sir Andrew Clark, that asthma is really due to urticarial swelling, and not to spasm of the bronchioles, is mentioned.

The author's favorite treatment seems to be antipyrin, in twenty or thirty grain dose at bed time, and the external use of a solution of glyceride of lead (in water one part to 20) salicylic and carbolic acid ointments are also mentioned, and among internal remedies; salicylates, colchicum, bromide of poatsh, and

pilocarpin. Although having had some success with pilocarpin, the author also advocates atropine in doses of 1-120 to 1-100 grain.

Dr. Henry Handford describes a case of

**Dermatitis Exfoliativa Pigmentosa.**

The patient was a gray-haired man of 55 years, formerly with light complexion, but now of almost the color of a Hindoo, or mulatto, without having any symptoms of Addison's disease. The only complaint is of itching and irritation of the skin; which is found on examination rough, scaly and somewhat indurated.

One day in summer, thirteen years ago, he scratched his leg, while mowing and very much heated, and it became inflamed and remained so ever since, at intervals. The inflammation spread to the other leg, and when working and perspiring large blisters would form on the buttocks, dry, and peel off. In 1893, during hot weather, the eruption spread to arms, face, and trunk, and the pigmentation began, the groins and axillæ becoming darker than the trunk.

Shortly before admission to the hospital, he says, a large double handful of scales could be daily collected from his bed, but during his stay this was much less.

The condition resembled argyria, somewhat, but there was no history of the use of silver salts; the mucous membranes were not affected, and the coloration has diminished of late. Arsenical coloration is not usually so intense or universal, but the author says the color was similar in a case which he has described. The quantity of arsenic taken by this patient is thought to have been small (liquor arsenicalis in five minim doses from September 2d to October 20th.)

The treatment the author used was quinine, warm baths, and a solution of gelatine painted on the affected parts and covered by gauze bandages. Under this the skin became softer and moist, desquamation ceased but the pigmentation was unaltered.

Dr. John T. Bowen describes an

**Epidemic of Alopecia Areata,**

which he had an opportunity of seeing and which has been previously mentioned elsewhere.

The epidemic occurred in an institution, and of sixty-nine children, inmates, sixty-three developed the disease. Microscopic examination of hairs from the margins of the patches was made in numbers of cases; but nothing could be found to indicate tinea, no broken hairs, no scales, etc., no parasitic growth. Bits of skin could not be obtained. The only peculiarity found in this group of cases was that many had a large number of lesions so small that it was difficult to determine that any existed. Four girls of fifteen and over, and all the matrons and adults, escaped. The cases improved, but different varieties of treatment seemed about equally beneficial, and the child first affected, although not more severly attacked, appeared to be the last to get well.

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## MEDICINE

### Treatment of Chronic Heart Valve Disease.

Dr. James Tyson (*Amer. Jour. Med. Sci.*) points that relief is often obtained from the occasional use of pergatives—five to ten grains of blue mass, followed by a saline, or the continuous use of small doses—one-half to one grain thrice daily. The greater apparent effect of the infusion of digitalis is due to its use in larger dose, although it is likely to be better borne by the stomach. Strophanthus, better borne by the stomach, has been used in doses of ten minims every two hours for forty-eight hours without interruption. Caffein in three-grain doses every three hours, in mitral regurgitation, is admirable, but is likely to produce insomnia. Sparteine in one-quarter, increased to one-half grain dose, three to five times daily, is of value if a diuretic be desired. For irregularity of heart action and palpitation, more common in mitral disease, belladonna is very useful. A belladonna plaster placed over a palpitating heart is a most efficient agent. Nitroglycerin, one-hundredth of a grain, increased to double the quantity, three times daily, often serves to the same end.—*Med. Standard.*

### The Treatment of Biliary Calculi.

M. A. F. Plicque (*Gazette des Hopitaux*) gives the treatment of this condition as follows:

1. With regard to the pain it may be regarded as of two forms: (*a*) Violent attacks of pain. In this form, apply very hot poultices with laudanum in them. Internally, gtt. xx. to xxx. laudanum, ext. opii and belladonnæ in gr. 1-6, every half hour till relieved. Sometimes inhalations of chloroform have been resorted to. (*b*) There is another form of pain that recurs from day to day, but is not so violent as the above type. This form is best treated by the use of narcotics, prolonged hot baths, revulsion over the liver by leeches in strong subjects, and a milk diet.

2. The means for the expulsion of the calculi are numerous. Some have tried and vaunted the use of ether; others glycerine; some again have found benefit [illegible] salicylate of soda. This is specially useful in angiocholitis. The best agent for the expulsion of these calculi is olive oil. This is usually well borne. When there is much revulsion to its use, the stomach tube should be employed.

3. The treatment in the interval. The best agent still is the olive oil. Alkaline waters are useful. Durande's mixture of essence of tur-

pentine 10 parts, and ether 15 parts, in quantities of 2 to 4 grams daily. Chloroform water relieves the flatulent dyspepsia in these cases. If there is any evidence of angiocholitis, salol ought to be administered. This is the best biliary antiseptic we possess.

4. The hygienic treatment must be kept in mind. Proper exercise is of value in restoring the balance of health.

5. Dietary. This should be plain. Abundance of water is indicated. Light, white wines are the only forms permissible. No heavy or indigestible food should be taken. Fresh fruits and vegetables are proper elements of the diet.

6. Medicines. Alkaline waters, as vichy, etc. Laxatives should be used, but strong purgatives should not be employed.

### A New Method of Politzerizing.

Every one who has tried it knows how difficult it is to get the patient whom it is intended to "Politzerize" to swallow at the proper moment. Under these circumstances, and as this plan of clearing the Eustachian tube is just now very much in vogue, our readers may be glad to know of a novel and vastly more simply way of attaining the object in view. In Politzer's method, as is well know, in order to prevent the air insufflated into the nose from escaping through the pharynx instead of passing into the tympanic cavity, the patient is asked to sound certain vowels or to swallow a mouthful of water, because in uttering certain vowel sounds, and during the act of deglutition, the soft palate is applied to the posterior wall of the pharynx. The naso-pharyngeal cavity, however, is only partially excluded by these means, and that for a very short time. Dr. Roydan therefore suggests that the patient be directed to take a deep inspiration and then to blow out the air through a small aperture between his closed lips So long as the patient blows the velum palati remains in contact with the posterior wall of the pharynx, and Politzerization can be performed without the slightest difficulty.—*Ex.*

### Marriage, Dysmenorrhœa, and Hysteria.

Wythe Cook (*Am. Jour. of Obstet.*,) finds from experience that in most cases of dysmenorrhœa and hysteria amongst single women marriage aggravates the disease. Hysteria is by no means cured by marriage, dysmenorrhœa often returns after pregnancy. One patient suffered from very severe dysmenorrhœa. She married, on advice, but the disease was aggravated by coitus. Conception occurred, and she fully believed that pregnancy would cure her, but the menstrual pain returned immediately after weaning. Another patient, subject to dysmenorrhœa, married when 20, and became pregnant when over 23. She bore a healthy child, and then took to the morphine habit. Her husband died a few months after her confinement. The period was suppressed for five years. After she ceased to take morphine it reappeared, at first irregularly, and at length in due season, but in both cases there was severe pain. She married again, and has remained eighteen months sterile; the dysmenorrhœa continues. A young woman subject to headaches and hysterical manifestations attended with hallucinations and depression got married. The neuroses were not improved by marriage. A robust young lady free from hysteria married, and bore two children within twenty-one months after marriage. Hysterical swoonings occurred during the pregnancies. A patient subject to dysmenorrhœa and hysterical fits married and bore five children. The menstrual pain never reappeared after the first pregnancy, but the fits still occur.

### Enteric Fever; Perforation; Peritonitis; Recovery.

Newton (*Chicago Med. Rec.*) has reported the case of a lad, 17 years old, who came under observation on the third day after having taken to his bed, with diarrhœa, tympanites, and pain in the right iliac fossa. The temperature was elevated and rose spots were present upon the abdomen. Restriction of the diet to milk and beef-tea, and the administration of a mineral acid and pepsin, and bismuth, salol, opium, were followed by amelioration in the symptoms. On the seventh day, however, the temperature again rose, the pulse became accelerated, small and thready, the face pinched, the skin cold and clammy, the tongue dry, and the abdomen tympanitic and extremely sensitive. It was learned that during the previous night, while a movement of the bowls were taking place, sharp, acute pain was felt in the side. Perforation of the bowel was diagnosticated, and celiotomy advised but not acquiesced in. Morphin, strychnin and whiskey were repeatedly administered, and by the following day the patient had rallied somewhat. He remained in a precarious condition for several days, when he gradually began to gain ground. For the succeeding three weeks the temperature pursued an irregular course and the diarrhœa was particularly obstinate. After the lapse of another week indications of the presence of an abscess between the anus and the scrotum appeared, and three ounces of fetid pus was evacuated. Through the opening made a probe could be introduced into the abdominal cavity for a distance of ten inches. The opening was kept patulous by means of gauze, which was removed after the lapse of twelve days, and the external wound was permitted to heal. From a few days after the occurrence of the supposed preforation complaint was made of a particularly sore spot, about three inches in circumference, below and a little to the left of the umbilicus, and over which percussion yielded a dull note. It is believed that the spot indicated the situation of the local peritonitis that existed, and which remained local from the formation of intestinal adhesions as a result of the exudation of plastic lymph. As peculiar features of the cases are pointed out the early date of the occurrence of perforation, the situation in which the abscess pointed, the failure of the temperature to decline, and the absence of vomiting.

### A Certain Sign of Death.

Mons. W. Necati (*La France Medicale*) reports to the Academie des Sciences the results of his experiments with a new instrument he has had constructed for the purpose of testing the ocular tensions. He has found that during life, tension varies from 14 gram. to 25 gram. Within half an hour after death, this tension has fallen from 1 gram. to 3 gram., and in two hours after death has become complete. As soon as the pulse ceases, the ocular tension falls, and steadily declines for two hours. An eye that has been enucleated and replaced in the orbit acts in the same way. By the time the loss of tension is complete, the body must have been dead at least two hours.

## SURGERY.

### The Principles of the Treatment of Gonorrhœa.

Professor Neisser, the distinguished discoverer of the gonococcus considers that all rational treatment directed towards the cure of gonorrhœa should be based upon the recognition of that micro-organism as the pathogenic principle of the disease. The greatest difficulties encountered in its eradication are that it does not remain localized in the urethra, but spreads to the cord, epididymis, prostate, and bladder in the male; to the uterus, tubes, ovaries, and peritoneum in the female; and that the virus in the later stages is situated deep beneath the epithelial layers, extending thence to the surface or deeper tissues, thus forming a chronic source of infection. It can only be easily reached in the first stages. The aim should be to prevent an invasion of the deep urethra and not to allow the disease to become chronic.

Treatment should be begun as soon as possible. The substances used must be (*a*) such as will kill gonococci, (*b*) which increase the inflammation as little as possible, (*c*) which do not injure the mucous membrane. Such are nitrate of silver 1-4000 to 1-2000; ammon. sulpho-ichthyol., 1-100; weak Rotter's pastilles, free from carbolic acid and mercury, 1 pastil to 250 of water; bichloride of mercury, 1-30,000 to 1:20,000. Pure astringents in the early stage are unsuitable, as they may serve to spread the infection. Cauterizing solutions of great strength, which may cause stricture, are dangerous, as are also most mechanical methods, such as the endoscope, bougies, etc. The best treatment is the early and frequent antiseptic irrigation of the urethra. For practical reasons, viz., the wide spread of the disease, injections with large syringes must generally be used instead of irrigations.

In the female the treatment should consist of thorough mechanica cleaning of the urethra and cervix, also using douches and injections.

The general dietetic, hygienic, and antiphlogistic measures are useful, and should be employed as far as possible. In all cases not very acute the presence of a posterior urethritis should be recognized and treated locally if an examination discloses the presence of gonococci. The treatment should not be limited in duration, as the aim should be not rapidity, but certainty. In chronic cases it should be determined if the discharge is infectious, and if it is so it should be treated by irrigations or instillations. If it is simple we must be guided by the pathological and anatomical changes in the mucous and submucous membrane as to the line of treatment it is best to employ. For the most part these cases require no treatment at all. When the deeper tissues are affected, sounds, instillations, the endoscope, and massage should be used.

The successful treatment of gonorrhœa in the female is attended with much more difficulty than in the male, and without frequent microscopical examinations judgment as regards the therapeutic result is impossible. Treatment should be begun as soon as possible and followed up most energetically, as the tubes, uterus, ovaries, or peritoneum, once infected, are very difficult to cure, frequently necessitating grave surgical operations.—*International Medical Magazine.*

### The Early Diagnosis and Practical Surgery of Cancer.

Herbert Snow, M. D., London, (*Am. Jour. Med. Sciences.* Great stress is laid upon the importance of early diagnosis. Early diagnosis, while difficult, can be greatly aided by remembering that "malignant lesions are especially prone to attack degenerating organs and degenerating people. With the exception of a numerically small congenital group of tumors which I have elsewhere classified under a special term, *blastoma*, and which mostly differ from ordinary cancer in rising spontaneously, malignant new growths are almost entirely confined to women above the age of 34, to men past 40. Further they appear in organs which have fulfilled their purpose and are undergoing devolution, or else intestines whose vitality has become conspicuously impaired."

Every tumor first noticed in the breast at or after the thirty-eighth year epoch is, in the great majority of cases, principally malignant; in the remainder it is certain sooner or later to become associated with malignant features in one form or another. From this sweeping rule, the most sweeping cyst within the gland parenchyma, a dilated acinus or dilated duct is not exempt.

Again it is laid down as an axiom that no average species of malignant tumor in the adult ever appears without an adequate and generally ascertainable cause.

About 11.7 per cent. of cases of cancer of the breast follow sudden injury—a blow or fall; the remainder are consequent upon some agency of a neurotic character impeding the normal devolution of the mamma.

Dr. Snow lays great weight upon "mental distress." He states that he has "known of one or two cases" follow an attack of influenza.

These statements cannot be accepted as in any way proven, although they should be given careful consideration as coming from a

man whose opportunities for observation in this disease have been exceptionally great. The mere fact that a cancer was first noticed shortly after an attack of influenza gives no scientific proof that such attack was an exciting cause rather than a coincidence. The fact that influenza is a disease so widely prevalent still further weakens the argument.

The physical signs of cancer are very well described.

In doubtful cases he believes that too much reliance should not be put upon the microscope, and cities the case of the late Emperor Frederick as a striking example.

Being of the cancer age and "suffering from steadily progressive laryngeal symptoms, the *a priori* probabilities in favor of epithelial cancer were very considerable. Yet in fallacious reliance upon certain microscopic indications of no more than merely negative value, the only measure which afforded a prospect of cure was rejected with quickly fatal result."

"The same historical event further demonstrates what is familiar to the practitioner in cancer, that the microscope for diagnostic purposes is of doubtful use."

Its conclusions may be taken without hesitation for positive purposes, but rarely or never for the negative. They may show that cancer is present, but cannot be trusted to prove its absence.

Treatment is briefly dealt with. Each case should be treated on its own merits. Early and very thorough removal when possible, but severe and protracted operations upon persons already in an exhausted condition from long standing malignant disease are greatly to be deprecated.

Under existing conditions of practice, wherein cancer is seldom brought to the notice of the surgeon in its incipient stages, comparatively few operations should take place, but these should be searching and thorough.

The writer strongly advocates opium, and believes that opium persistently given from the earliest moment at which there is reason to believe the disease incurable by surgical means, not only materially prolongs the individual's life, but also has often a more marked effect in arresting the growth.

Iron, arsenic, quinine tonics in general are useless except as *placebos*."

---

### Aseptic Surgery for the County Practitioner.

Dr. James B. Bullitt makes the following observations:

1. Coats and cuffs should be removed, a clean apron or towel fastened over the front; hands and arms are scrubbed in hot soap and water; special care is to be given to the nails; the hands are then rinsed in boiled water or alcohol.

2. The field of operation is rendered aseptic by being thoroughly washed with soap and warm water, any hair being shaved. This is followed by alcohol or ether.

3. Sheets, towels, aprons, etc., can be completely sterilized by being scrubbed and then boiled in a five per-cent. solution of washing soda.

4. Ordinary cheese or butter-cloth makes an excellent gauze, and can be sterilized by being placed in a steam sterilizer for an hour. It is then put in a jar that had been boiled and tightly stoppered. Iodoform can be sprinkled over it when needed.

5. The best sponges are cotton-wool tied in butter-cloth and placed for an hour in the steam sterilizer. Sterilized heavy linen make good substitutes for large flat sponges in abdominal operations.

6. Silk for sutures is sterilized by being boiled for fifteen minutes in the soda solution. It is then dried in the sterilizer and placed in sterilized, stoppered bottles, containing a five-per-cent. carbolic acid solution.

7. For flushing out a cavity, nothing is better than boiled water, or a physiological saline solution that has been boiled.—*American Practitioner and News.*

---

### The Surgical Treatment of Pulmonary Cavities.

From a study of the present aspect of the surgery of the lungs, Dandridge (*Annals of Surgery*) conclues that a certain number of pulmonary cavities can be successfully dealt with by incision and drainage. Tuberculous cavities in the lower portion of the lungs, if single and superficial, and if the general condition of the patient permits, should always be opened. Cavities at the apex should only be opened when there is free and persistent fetid expectoration that has resisted treatment, and the remainder of the lung is not involved. Abscess, gangrene, and hydatid cyst should be opened and drained whenever they can be located. Closure of the pleura should be insured before the evacuation of a cavity is attempted. In case of pyo-pneumothorax the fistulous track should be explored, and any cavity freely laid open by means of the cautery. Cavities that have been opened are best treated by packing with gauze, preferably impregnated with iodoform. The further careful trial of such agents as iodoform, chlorin-gas, and zinc chlorid is desirable to determine whether or not the tuberculous infiltration may be modified by them. It is also desirable, for the further extension of surgical interference in pulmonary cavities, that the means of locating such cavities and of determining their size and the exact character of the tissue that overlies them should be perfected by further study, and for the accomplishment of this the surgeon must look to the physician.

---

### The Early Treatment of Carcinoma Uteri.

Kelly contributes a valuable summary of this subject to the *New York Medical Journal.*

The large number of cancer cases constantly applying to Kelly for relief have induced him for the past three years to adopt certain

stringent rules with regard to his own patients, which he has taught for the same period in his lectures at the Johns Hopkins Hospital.

The end in view is two-fold. First, by treating cervices liable to become cancerous, and thus prevent the formation of this neoplasam; and secondly to detect cancer of the cervix at a sufficiently early date to successfully eradicate the disease.

1. It is the duty of the obstetrician to see each patient at his office from two to three months after her confinement, and there to examine and make a careful record of the condition of the pelvic structures, stating accurately what lesions have been produced by the confinement.

2. Cervical lacerations should be carefully described, noting the position and depth of the tear and the appearance of the lips. Lacerations require no treatment when the lips are thin, uninfiltrated, and lie together. Thick, infiltrated, and everted lips associated with cervical catarrh call for depletory treatment, followed by repair of the laceration.

3. Every woman who has passed thirty-five years of age and has borne a child should have this examination made without delay by a compitent physician, and if the cervical lips do not appear perfectly sound she should be kept under observation and examined at intervals at from six to eight months.

4. Every woman over thirty-five, with a cervical tear, should be examined at least once a year for ten years, or longer, if the appearance of the lacerated area is not perfectly healthy.

5. These rules apply with special force to patients whose family history shows a marked inclination to cancerous diseases.

If these rules are conscientiously observed there is not a shadow of doubt but that thousands of lives would be saved yearly in this country alone by timely interference with a disease so markedly local and accessible in its origin.

The author states that he feels that while we are searching for a cure for cancer, the line of progress in the immediate future for the gynæcologist is clearly in the direction of prophylaxis and anticipation, either preventing or discovering the malady in its earliest stages.

## ARMY AND NAVY.

### CHANGES IN THE U. S. ARMY FROM APRIL 15, 1894, to APRIL 21, 1894.

Captain Nathan S. Jarvis, Assistant Surgeon, will be relieved from duty at David's Island, New York, upon the arrival of Captain Samuel G. Robinson, Assistant Surgeon, and will report in person to the Commanding Officer, Willett's Point, New York, for duty, relieving Captain William P. Kendall, Assistant Surgeon. Captain Kendall, upon being so relieved, will report in person for duty at Fort Columbus, New York.

PROMOTION.

Captain James C. Merrill, Assistant Surgeon, to be Surgeon with the rank of Major, March 13, 1894, vice Bartholf, retired from active service.

First Lieutenant Allen M. Smith, Assistant Surgeon, will be relieved from duty at Fort Custer, Montana, at the expiration of his present leave of absence, and will report in person to the Commanding Officer, Fort Reno, Oklahoma Territory, for duty at that post. First Lieutenant James M. Kennedy, Assistant Surgeon, is relieved from duty at Fort Riley, Kansas, and ordered to Fort Custer, Montana, for duty.

By direction of the President, Captain Alonza R. Chapin, Assistant Surgeon, will report in person to the President of the Army Retiring Board at Fort Bliss, Texas, for examination by the Board.

The leave of absence granted Captain Ogden Rafferty, Assistant Surgeon, is extended eighteen days.

First Lieutenant Charles Willcox, Assistant Surgeon, is relieved from temporary duty at Angel Island, California, and will rejoin his proper station, the Presidio of San Francisco, California.

### U. S. MARINE HOSPITAL SERVICE FOR THE FIVE WEEKS ENDING APRIL 21, 1894.

Murray, R. D., Surgeon, to inspect Quarantine Stations of Florida, April 17, 1894.

Bailhache, P. H., Surgeon, to proceed to New London, Conn., as Inspector, April, 18, 1894.

Mead, F. W., Surgeon, to report to Chairman Committee on District of Columbia, U. S. Senate, for special duty, April 7, 1894.

Carmichael, D. A., P. A. Surgeon, to report to Medical Officer in Command at San Francisco, Cal., for temporary duty, April 11, 1894, to proceed to Port Townsend, Washington, and inspect M. H. S., and Quarantine Service, April 21, 1894.

Brooks, S. D., P. A. Surgeon, to proceed to Chicago, Ill.,, for temporary duty, April 3, 1894.

Bratton, W. D., P. A. Surgeon, to report at Bureau, April 16, 1894, to proceed to Riedy Island, Quarantine, and await orders, April 20, 1894.

Vaughan, G. T., P. A. Surgeon, detailed as Chairman Board for Physical Examination of Candidates, Rev. Marine Service, March 19, 1894.

Cobb, J. O., P. A. Surgeon, to proceed to Seattle and Tacoma, Washington, as Inspector, April 12, 1894.

Wertenbaker, C. P., P. A. Surgeon, granted leave of absence for two months, April 3, 1894.

Brown, B. W., Assistant Surgeon, granted leave of absence for six days, April 7, 1894.

Decken, C. E., Assistant Surgeon, placed on "Waiting Orders," April 1, 1894.

Strayer, Edgar, Assistant Surgeon, to proceed to Vineyard Haven, Mass., for temporary duty, April 4, 1894.

Oakley, J. H., Assistant Surgeon, to proceed, to San Francisco, Quarantine Station for temporary duty, April 11, 1894.

Prochazkae, Emil, Assistant Surgeon, to proceed to Cleveland, Ohio, for temporary duty, April 2, 1894.

## ORIGINAL ARTICLES.

### ENDOMETRITIS: ITS PATHOLOGY, SYMPTOMATOLOGY AND TREATMENT.*

WILLIAM W. STEWART, Columbus, Ga.

In beginning the discussion of this subject, I do so feeling that upon these lines of reasoning hang the only true conception of endometritis and its treatment; these conclusions are drawn from a large clinical experience and a close study of its pathological conditions. I will classify the conditions as simply as possible, take up its etiology and pathology and discuss its treatment from the standpoint of its pathology.

We have simple, septic and gonorrhœal. Under the head of simple are gathered all those conditions inflammatory in character, invading the endometrium produced by the following causes:

Displacements causing chronic congestion and hypertrophy.

Imprudent exposure during menstruation.

Retention of menstrual flow or mucus by cervical obstruction.

Sexual abuse, either in intercourse or masturbation.

Fevers, eruptive and protracted simple.

Frequent miscarriages.

Traumatism by intra-uterine instrumentation or pessaries.

Under the head of septic are gathered all those causes by which septic material or germs are implanted upon or within the mucosa, as by dirty instruments or hand.

Decomposing menstrual blood or lochia infected by lack of cleanliness at menstruation or abortion. (Those forms arising at confinement come rather under the head of puerperal fever).

Torn perineum, which makes of a normally closed vagina a cavity frequently filled with air, thus opening broad avenues for infection.

Gonorrhœal alone caused by introduction of the gonococci.

We may find the pathology of simple metritis one of two forms:

Primarily, and by far the most common, is a hypertrophied condition of the mucous membrane follicles, tortuous but retaining in its integrity its epithelial covering which presents a swollen appearance; muscular walls thickened, often causing decided enlargement of uterine body; blood vessels engorged and turgid, aiding in the local œdema; small capillaries multiplied in number and distended with blood, bleeding freely on slight traumatism or over-exertion; crypts between follicles filled with glairy mucus and lymphoid cells which are constantly discharged as a leucorrhœal discharge.

From the super-nutrition produced by the over-supply of blood, there often springs into existence fungosities, which are truly hyperplastic cells; or following a confinement or abortion, small particles of decidua or placenta may remain, which take on new life and growth forming fungoid masses. In either condition, there is constantly thrown off a mucoid discharge, varying in color by the number of lymphoid and desquamated epithelial cells which it contains. Either of these growths at the menstrual period may produce metrorrhagia and often alarming hemorrhage.

Secondly: The atrophic form in which the uterine walls are hardened by sclerosis,

*Read before the Georgia State Medical Association, April, 1894.

the mucous membrane almost devoid of epithelium and closely adherent to submucosa, crypts few in number. This condition is always a secondary one, and is invariably associated with amenorrhœa and dysmenorrhœa of a distressing and intractable form.

The symptoms and many complications arising from endometritis are of much interest, illustrating more perfectly the effect of the sympathetic nervous system on the different organs of the body and the general health than any other disease. The leading symptoms of endometritis are headache, occipital and parietal in location; flatulence; indigestion, fermentative in character, produced by dilation of the stomach, which is almost constantly associated with endometritis of long standing; pain in either breast, usually the left; great fatigue from exercise; leucorrhœa distressing in character, in the acute forms quite profuse and sometimes of very bad odor. In the atrophic form the leucorrhœa is absent or very slight, but all other symptoms are usually present in aggravated form. In both forms, the nervous system is thoroughly shattered, often producing hysterical phenomena whose form is legion. Sufferers from this trouble quickly develop a decided cachexia, often suggestive of malignant trouble, though none exists.

The treatment of the simple acute endometritis is almost sure to yield prompt and good results when the condition does not exist in an aggravated form, and can be taken early. The greatest benefit and flattering results can be obtained by change of air, well-regulated hygiene, exercise and nutritious diet, combined with a judicious administration of chalybeates and arsenic. At the menstrual period, rest in bed throughout its course, to be continued for at least four successive months. Metrorrhagia and dysmenorrhœa, if they exist, are well controlled by the judicious use of fluid extract of viburnum prunifolium, hydrastis and cannabis indica.

It is, however, the misfortune of both physician and patient, that when the metritis first makes its appearance, it is looked upon as a matter of small moment, the result only of a bad cold or over-exertion; or if the family physician is called, he is too prone to pass it by unheeded, with the remark: "If it trouble you, let me know." By slow degrees, the once simple condition passes into one which demands attention. And let me urge that that attention be prompt and decisive; for only by such measures will perfect results accrue. There are three lines of treatment to be selected from under these conditions, depending upon the variety and extent to which the process has advanced. In the simple acute, just passing into the more aggravated forms, and in the atrophic variety, simple gauze packing will in many instances prove all that is required.

To insure good results in performing this operation and to steer clear of the rock of sepsis, upon which so many surgical crafts are wrecked, it must be borne in mind that the vagina contains at all times thousands of pyogenic cocci, and it would be easy through this medium to infect a previously uninfected endometrium, thereby exchanging the simple for the septic form with its legion of complications.

To avoid such dire results, the strictest laws of antisepsis should be observed. A vaginal douche of one of two thousand sublimate solution should be given; then the external genitals should be thoroughly scrubbed with tincture of green soap and warm water, a perfectly clean speculum then introduced and vagina and cervix well wiped off with pledgets of absorbent cotton, dipped in a sublimate solution of one to two thousand; cervix should then be caught with a tenaculum and drawn forward, thereby straightening cervical canal; cervical canal should then be wiped out with absorbent cotton on an applicator having previously been immersed in same solution. If necessary, cervical canal should then be slightly dilated, cervix being steadied by tenaculum, a long strip of iodoform gauze three-quarters to one inch in width and fifteen to twenty per cent. in strength is looped over the end of a smooth uterine sound, and gently introduced to fundus; the sound is then withdrawn and point again entangled in gauze at the mouth of cervical canal, and gently introduced, thus loosely packing the uterine cavity with gauze. It is then clipped off about one inch from cervix, and a wider strip is introduced in the vagina over and around cervix. Covering this with a pledget of sterilized or borated cotton and operation is then complete.

This dressing is allowed to remain unmolested four or five days, patient prefer-

ably remaining in bed. This, however, is not absolutely essential to a successful result, as she may be permitted to remain upon a sofa or recline in an easy chair.

On the fourth or fifth day this dressing is removed, with the same precaution, and again packed. This procedure is repeated, if necessary, four or five times. If menstrual flow should appear, remove dressing and repack fourth day after its disappearance.

This treatment insures drainage and an aseptic healing dressing to an inflamed and œdematous mucous membrane in the more acute forms, and to a mucous membrane below the normal in its nutrition in the atrophic. In both instances, a perfectly scientific procedure which recommends itself from every standpoint of common sense and good surgery.

In the acute forms, this treatment by drainage and antiseptic dressing, quickly brings about resolution and restores the engorged uterus to its normal condition. In the atrophic it stimulates and insures better nourishment to an impaired and partially destroyed mucous membrane, and thereby often, to some extent, removing the troublesome dysmenorrhœa and amenorrhœa.

In the severe forms of the septic which have become chronic in character, with troublesome symptoms, curettage should precede the gauze packing, as already described.

The septic form in its acute invasion, presents a picture once seen, never to be forgotten, and as differentiation between gonorrhœal and septic can only be made by the microscope, this clinical picture will represent both.

A patient after miscarriage, abortion, dirty instrumentation, the wearing of a stem pessary or the introduction of the gonococci, is first taken with headache and languor, followed by chills and fever, usually high, micturition is usually frequent, urine small in quantity, bowels constipated, tympanites more or less constant, depending upon extent of invasion of pelvic peritoneum, pelvic region tender on pressure, and colicky uterine pains gradually becoming a dead ache. Examination reveals vagina hot and bathed in muco-pus, more or less hemorrhagic, uterus engorged and exquisitely tender to touch, exudative masses may be found surrounding uterus if adnexa be involved.

By speculum examination a large, turgid, often bluish cervix is exposed, from which there is constantly discharged a ropy muco-pus; cervix may be eroded, and in cases of late abortion and post-partum origin, patches of diphtheritic membrane may be found upon cervix and vaginal walls, due to the presence of the streptococci.

Endometritis, when produced by the gonococcus, is usually less rapid, and rarely causes death; whereas, in the septic form, death not infrequently draws a veil around the victim.

Whenever these conditions present themselves, never hesitate; act with prompt, thorough, clean and determined intent; with such, good results will surely come, and many lives of suffering and invalidism caused by diseased adnexa will be saved. Treat the disease as common-sense and good surgical rules surely dictate.

What surgeon is there to-day, who, having such a condition in any other portion of the body, would not make it his first step, his foundation for further treatment, to thoroughly cleanse the septic cavity, following it by good drainage?

Strike off the shackles of ignorant timidity which hold to vaginal douches, hot poultices, and lead to high mortality.

To thoroughly cleanse this cavity by referring to its pathology, it is found that staphylococci and streptococci are almost entirely found in the mucosa, rarely penetrating to the muscular wall; mucous membrane is bathed with pus, and in aggravated forms, the mucosa at times necrotic.

In the gonorrhœal the gonococci rarely pass deeper than the lymph spaces beneath the epithelial lining.

This being clear, the first step suggested is to remove the infected tissue which should be done thoroughly; a half procedure is worse than none. This should be procured by curettage, a description of the method of which is given later.

The presence of pelvic exudate is no contra-indication, but rather an indication for curettage.

Curettage, under all circumstances, should be performed with the greatest care. Bowels should be thoroughly evacuated the night prior to operation, with free doses of salts; one hour prior t o administration of anæsthetic an enema of warm water should be given; vaginal douche of one to two thousand sublimate solution should then be given, and external genitals should be well scrubbed with hot water and tincture of green soap, after

which the vulva should be covered with a pad of sublimate gauze held in position by napkin.

After anæsthesia is complete, instruments being sterilized, a speculum should be introduced, and any mucus that may have collected in vagina washed out with stream of sublimate solution one to three thousand; vaginal walls and cervix should then be washed with pledgets of absorbent cotton soaked in same solution, and cervical canal cleansed with cotton wrapped upon an applicator, immersed in either carbolic acid pure, or sublimate solution; cervix should then be caught by tenaculum, drawn down and steadied, dilator introduced and cervical canal well dilated; intrauterine washer should then be introduced, and uterine cavity washed with sublimate solution one to six thousand, after which dull curette is introduced to locate any decidual tufts, polypi or granulating masses; sharp curette should then be used with slow, regular strokes from fundus to external os, mucous membrane should be stripped off thoroughly, when sides have been completed, fundus should be treated in same manner, and successively curette should be rotated in each cornua, curette should continue till the sensation peculiar to the contact of the curette to muscular tissue is detected, and in all cases where uterus is not intensely softened, as in the puerperal state, there is a sound produced, harsh and grating in character, when the muscular wall is encroached upon by the curette; if as in the puerperal uterus, the muscular wall is very soft and danger of perforation is great, a rather flat, broad and moderately sharp curette should be used, and great care should be exerted to detect immediately the sensation produced by the muscular coat upon the curette.

Though the danger of perforation by sharp curette is so loudly sung, in careful hands, skilled in such work, such an accident should never occur. After curettage, uterus should again be washed out with sublimate solution, one to six thousand, till water returns clear; vagina should then be thoroughly cleansed, and uterus well packed, as already described. Vagina should be loosely filled with strips of gauze, and vulva pad of sublimate gauze applied, to be changed every six hours; water should be drawn at each dressing, and dressings allowed to remain unmolested as long as temperature remains down, till four days shall have elapsed, when it should be removed, as before. If temperature remain up, which is unlikely, dressings should be removed after twelve or twenty-four hours, as indicated by temperature, and uterine cavity again douched with sublimate solution one to six thousand, and uterus repacked as before. If temperature remain down, dressings can be left from five to six days, when they should be removed with antiseptic precaution, this treatment being continued till recovery is complete; the gauze insures perfect drainage, and with this plan of treatment laid down, temperature quickly falls, and pelvic exudations soon disappear.

In the septic and gonorrhœal forms, peritonitis may exist, and if so, bowels should be flushed daily by salts; should nausea exist, precluding the use of salts, enemata of

℞ Glycerine..... oz. 6
Oxgall (fresh)..... oz. 1
Rochelle Salts..... oz. 6
Aquæ q. s..... qts. 1
M. Use as one enema.

This should be given thirty inches up the bowels by high enema tube, and repeated as required.

By this treatment, rest and comfort, far greater than by morphine, will be produced, and "Nature's peritoneal drainage tube," as Lawson Tait has termed the intestinal canal, is constantly relieving the peritoneal cavity and general system of noxious material.

Beware of the delusion, often by temerity becoming a snare, of making applications of caustic agents to cervical canal as there exist authority for by many writers.

The best result that can be hoped for by such treatment is temporary amelioration of the condition. If the simpler forms are not made septic by the absorption of necrotic tissue produced by these agents, it goes on from a simple congestion thoroughly curable, to the atrophic form virtually incurable.

Caustics destroy the mucosa, and in its place scar tissue is substituted, through which the patient is compelled to menstruate. The sufferings of such an one may well be imagined.

In the cervical canal the severe caustics lead to cystic degeneration of cervix, produced by cicatricial contraction closing the ducts of the cervical glands.

On the other hand, after curettage and gauze packing, the mucosa is regenerated, fresh and healthy.

# HYDROPHOBIA.

HIRAM CORSON, M. D., PLYMOUTH MEETING, PA.

[CONTINUED FROM PAGE 631.]

## CASES.

As I have already stated, the committee appointed to report on this disease by the American Medical Association presented 106 cases which I have carefully read. In nearly all of them the predominance of the excited nervous system masked all other functional derangements and caused the seeming suffering. There was scarcely a single case that differed from those which we know were spurious, false ones as proved by their being utterly cured by means acting on the nervous system. When I spoke to you on this subject some months ago, and doubted whether there had been a single well authenticated case in our county, or even in the State, during the last half century, I was told of two undoubted ones here: one in Norristown and the other only a few miles away. I have since investigated them.

The first case was that of JOHN EARNEST. At the time he was bitten his hiredman, Miles Burns, was also bitten by the same dog. The following is the latter's account of it:

Mr. Sullivan, the hatter, had a beautiful, favorite hound which had been kindly treated; a pet too, in his family, being much in the house. One day the dog was absent, the next day he walked into Mr. Earnest's office, a mile below Norristown, and quietly laid himself down under the desk. He was such a kind, gentle animal, apparently without an owner, that Mr. Earnest concluded to take him along home—a mile away. So he coaxed him from under the desk and taking a rope in his hand attempted to put it around his neck. The dog was not used to being tied and when the stranger took hold of him, bit him on one of his fingers. Mr. Earnest then called on Burns and they succeeded in putting a rope around the neck of the frightened animal, but while doing it, Burns was also bitten. They then brought up the light wagon to take him away. As soon as he saw the wagon he sprang into it and lay down under the seat. He had been accustomed to be carried in that way by his master. Earnest took him home, but in pulling him into the barn to tie him there, the dog again bit him pretty badly on the wrist. When next day Earnest came to oversee his "works," Burns saw that he had his arm bandaged, and as he had only been bitten on the fingers when at the office, Burns inquired why his arm was bandaged, and was told of the second bite on the wrist. The first night after the dog had been tied, he jumped out of a high window and as the rope was too short to allow his feet to touch the ground he was choked to death. On the second day after he was bitten, Earnest did not come to the works, as was his daily habit, and Burns heard no more of him for two or three days, when he heard he was dead. It was of course reported as a case of hydrophobia. How can we account for this rapid development of the disease and the premature death? The period of incubation, as already stated, is weeks, not a few days, and the most rapidly fatal cases never, or rarely, die in less than four to six days. Mr. Burns stated to me that Mr. Earnest, from the moment he was bitten, became very uneasy, fearing the dog was a mad one, and worried about it all the time. He did not know that he went to any "mad-dog" doctor, but Dr. Duncan, who attended him, doubted its being a true case. It was evidently a death from fear. Mr. Burns' family, after the death of Earnest, insisted on his going to Mr. Emery, of Phœnixville, of whom I have already spoken. He never felt afraid of being infected and nothing came of it.

CASE II.—Mr. Burgess, machinist in Norristown, said: "His own dog seemed well and was about the shop, when, suddenly, he jumped up and ran into the street where he behaved in a most unusual way for awhile, after which he darted back into the shop, and through it into the yard where he dashed around wildly and finally jumped down into a cellar window. A fellow workman stooped down,

caught him by the back of the neck and jerked him out, and while tieing him was bitten. The wound bled freely. Mr. Burgess said to him, "This may be death to you, perhaps." He replied, "That is my business." Mr. B. of course thought the dog was rabid. As he had heard that dogs would eat castor oil, and thinking possibly that it might be pain which caused him to act so strangely, he put some oil in a saucer, and securing it to a handle about two feet long, held it to him. He at once dashed at it and lapped it up. In a few hours he was well purged and soon quite well and continued so. The bitten finger healed naturally, even without antiseptic dressings, and the bitten man suffered no further."

ANOTHER CASE.—His beautiful Spitz dog was much admired by a visitor, who put his hand on his head to pet him. The dog turned and bit him. A few days after this, the dog was sold, or given to another person whom he also bit, but they did not kill him, as is the common bad custom. The dog continued well as did the bitten persons. Now if they had killed the dog, what fearful anxiety they would have had, and if failing to go to a "mad-dog" doctor, they would doubtless soon have had false hydrophobia, believed by those who heard of it to be the real disease.

JOHN HOWARD, janitor of a church in Manayunk, was bitten on the wrist while standing at the church door, February 15, 1892. He did not take any notice of the wound for one and one-half hours. When the people were leaving the church, he then thought about it, and saw some blood on the wrist. Then he went to Dr. Custer, who dressed it—without naming hydrophobia—by applying nitrate of silver, then covered it with iodoform gauze. His pulse was then 90 to 96. Wound healed without further attention. October 28, almost eight months after the bite, he came again to Dr. Custer. He said he had slight chilliness, with spells of heat and aching and soreness in his body, but especially from the tips of the fingers of his right hand (the one bitten) up to the shoulder and back of the neck. There was no redness of the bitten part. He had not eaten that day before coming to Dr. Custer; seemed well; pulse 96. Next morning pulse was 110. The pains in hand, scapula and neck were worse; the pharynx was not red all over as in scarlet fever, but there were small, red, isolated patches, and also an eruption on the sides of the tongue, which Dr. Custer had seen described as a symptom of hydrophobia. On this Dr. Custer laid much stress, as pointing to rabies. The patient had no aversion to water, but when it had gotten somewhat down the throat, he would throw his arms above his head and make a motion with the jaws, as a person does when first stepping into a cold bath. Sometimes when the throat was filled he would jump up a foot or more as if to get air, his head being thrown back and elevated. Thursday he was thirsty, but when he drank acted as before, as if gasping for air. At midnight of 26th was worse. Dr. Custer was sent for—he was wildly raving and his wife was afraid of him. Dr. Custer then gave him $\frac{1}{4}$ grain sulph. morph., and before 8 o'clock in the morning, $2\frac{1}{2}$ grains with ʒj bromide of potassium. No effect in producing sleep or contracting pupils. Pulse 117. Passed no urine from the evening when he took the first half grain of morphia until the evening of the 27th, about 36 hours, when the catheter was used. Friday Dr. Todd was called, and he and Dr. Custer both thought it a case of hydrophobia. Dr. Custer felt sure that the patient himself so regarded it, although not a word had yet been said about it. They advised his removal to the hospital, but a vestryman counselled a visit to Dr. Fry. The policeman's account of the trip as given to me is, "that he and another officer took him in a wagon. He rode quietly, talked to them, did not seem to be any way wrong. They asked Dr. Fry if he could promise to cure him. He said (in the man's presence) 'if he had not had a spasm he could. They,' meaning the Fry's, 'had cured them, even after having had a spasm. He would give him the medicine.' He did so, got his ten dollars and they started for home." Now mark what happened. They had barely started when he got spasms again and had them all the way home. While they were away at Lansdale, I saw a notice of the case and next morning, at 8 o'clock, I took the train for Manayunk. I was too late to see him. The officers, after having been up with him all night till 4 o'clock, had started with him to Blockley Hospital, and had then returned. All the way to the Hospital he had the spasms, as they called them.

CLINICAL NOTES*. — John Howard; white; aged 42 years; native of England; married; church sexton.

Admitted to hospital about 6 A. M. October 28, from Police Patrol No. 18, from Manayunk.

A friend who came with patient said he had been bitten by a dog on the 15th of February, 1893. The wound was on the dorsum of the right hand. The wound was *not apparent* on admission. It was said that ever since the bite he had been much worried about it himself, and that his friends had constantly worried him by talking of the dangers of hydrophobia occurring. Also that advertising quacks (?) had sent him much literature on the subject which had kept his mind constantly on the dangers of hydrophobia. It was said that he had been drinking "some," but not to be often drunk for the last two weeks.

On October 24th, 1893, four days before his admission it was said he had began acting strangely, to "bark," to be more worried than ever, and be anxious to go to Lansdale and consult a quack (?). He grew rapidly worse within the next 24 hours, being entirely maniacal at times, and finally went to Lansdale on the 27th of the month, for treatment. On his return home he became very violent and had to be restrained.

On admission to hospital his temperature was 102.8°, pulse 144, without tension, respiration 30 but not particularly labored. The expression was drawn, anxious, all the movements of the face appearing to be done under great tension, by jerks as it were, and yet there were no convulsions; the eyes were staring intently at whatever attracted them, but were moving about constantly, pupils moderately dilated and not rapidly mobile. The patient was constantly expectorating small masses of tenacious spittle, doing it with effort and throwing it far from him. He said very little and what he said was incoherent and more in moans than in distinct words.

There was no appearance of spasm or convulsion; the skin of the neck showed no unusual sensibility; the patient drank freely several swallows and then stopped, apparently from simple restlessness, before he had emptied the cup, and spat out some of the water. He grew more restless as the day advanced, having various hallucinations. He said he was afraid of "sulphur" coming from the screen around his bed; he could both see and smell it and was afraid it would choke him. He would jump up in bed in great fright when the nurse would go near him with towel to clean his face from saliva, saying that she wanted to choke him. He sank into a condition of exhaustive coma about 1 P. M., lying quietly, breathing labored, limbs absolutely limp, temperature 101.6°, pulse 128, respiration 24. He remained in this condition, not responding to stimulants until 5:30 P. M. when he died, having been the house about 12 hours.

The death was reported to the coroner, who sent for the body and posted it at the morgue, and at the inquest the coroner's physician stated that "the membranes and cortex of the brain were deeply congested and death due to Acute Mania."

TREATMENT.— Hyoscine hydrobromate gr. $\frac{1}{100}$ with morph. sulph. gr. $\frac{1}{4}$ once hypodermically. As cyanosis came on and continued he had three hypodermic injections of strychnine, gr. $\frac{1}{30}$ with digitalis gtt. xv. Also whiskey and ether by hypodermic method.

* *Department of Charities and Correction. Bureau of Charities, Philadelphia Hospital, Philadelphia, Pa. Daniel F. Hughes, Chief Resident Physician.*

PHILADELPHIA, Nov. 8, 1893.

My Dear Doctor Corson.—I am glad to be able to comply with any request of Dr. Corson's. I have been a firm and practical advocate of your scientific treatment of Lung and Puerperal fever ever since graduating in 1878. I was fortunate enough to have as teachers Dr. Gross, Sr. and Dr. E. Wallace, and they early had their commonsense views impressed on my mind.

The patient, John Howard, was admitted and died during my absence in Chicago. He was diagnosed as acute delirious mania by Dr. Roland G. Curtin, who was called in my absence. I having, when home, charge of all acute mental cases from the moment of their admission.

I enclose you copy of our records of the case.

Again expressing gratification at being able to comply with a request of one who I hold in such high esteem as yourself, I am,

My dear Sir,

Very truly,

D. E. HUGHES.

### FALSE HYDROPHOBIA.

Testimony shows that, in the opinion of physicians who have well considered this subject, there is much reason to believe that false hydrophobia is a very common occurrence, while true hydrophobia in man is almost never met with.

I have already shown you that John Howard's case was evidently the result of long brooding over the fear of what might

result from the dog bite, and the added fear produced by the unintentional but positive confirmation of those fears by the friends and by the physicians. While the result of the case in the Hospital, as seen by the physician there during his last few hours, and the post-mortem examination proved that it was a false case, the result of fear—*mental terror*.

The Earnest case, so extensively noised abroad and so unanimously believed by those who never saw the case, from the testimony of Mr. Burns was without a shadow of doubt a false one. There was in that instance no premonitory stage. It was mental terror, so strong as to take from its victim all control of his nervous system. Poor fellow! There he was, his mind confronted with the fearful fate, in his belief the certain result of the dog bite. No sleep, no drink, no food aiding the mental terror to drag him to the grave. It is not strange that four days in such a condition should end his life. And yet we all know that it was not rabies.

And Burgess' case. How instructive! A dog evidently mad, as they believed, and yet cured by a dose of castor oil, and the man bitten by him when in this apparently rabid state never affected by it, though taking no preventives. So, too, his second case. The Spitz dog. Had he been killed every one would have believed him mad, and the person bitten through fear of consequences would, in the opinion of the people, have died mad.

The justy eminent Dr. Wm. A. Hammond, of New York, I have already told you gives many most interesting cases of false hydrophobia. And to the case given by Dr. Leedom, I may add a case in my own practice.

In 1856 I was called to a tall, gangling young man who was suffering, the messenger said, from "some kind of spells." Through a heavy rain I made my way to the house on the Schuylkill Hills. On inquiring below stairs about the case, I was told they were sitting around the store, when this youth, of about 18 years, wriggled himself out of his chair into the fireplace close at hand, and rustled about in some cold ashes left there. The mistress of the house was evidently fearing some great danger to the youth. On going up stairs I found him stretched out on a bed with four men, one to each arm and one to each leg, holding him at full length. He opened his eyes to the utmost and stared at me but not a word would he reply to any question asked him. After feeling his pulse and observing his behavior for a few minutes—he was turning his head from side to side as far as he could get it and snapping his jaws together as if he was biting at those on the sides of the bed who were holding strongly to his outstretched arms—I retired and going to the mistress, the mother of two young men who were holding him, asked her what she thought ailed him.

"Oh, doctor, I don't know," she said. "What do you think is the matter with him."

"There is nothing the matter with him," I replied.

As if offended she said, "I don't like to hear you talk that way."

"Well," I said, "please listen to me. I will go with you to his bed-side and then without looking at him at all, will say to you, as though I regarded him as not knowing anything talked about, 'This is a very serious case, but bad as it is I think I can cure him. I want you to go downstairs and heat an iron to a red heat, and in the meantime I will give him a powder that, if it act well, will begin to make him better in five minutes, and in twenty minutes will cure him entirely; but if it should not, then we will strip him naked and draw that hot iron down over his backbone to the very end of it.'"

At once, her son who was holding an arm, cried out, "Why, doctor, won't it burn him?"

"Burn him? Yes, it will burn him to the very bone, but what of that? It will heal again, and nobody will see the scar there."

As the woman started to go down, she turned and asked, "What kind of an iron shall I heat, doctor?"

"Any kind. A plough cutter will do—the nose of a plough cutter will be the very thing."

He knew well what a formidable thing a red-hot plough cutter would be. She left to heat the iron and I dissolved a quarter of a grain of sulphate of morphia in a tablespoonful of water. When ready I said to him in a very imperative tone, "Open your mouth." Slowly he opened it and I poured it in. Then, sitting close to the bedside I took out my watch, and when five minutes had passed, I said, "He

has had it five minutes, and if it acts well he should feel a little better." And then looking him steadily in the face, said, "Are you any better?" He responded by a grunt in which I could not discern yes, but which showed plainly that he was understanding well what I asked. Still holding my watch so that he could see it, when the ten minutes had come I said, "Are you any better?" There was a very indistinct yes. The fifteen arrived and the response was a fair, audible, "Yes." I at once opened the door and called the mistress. "He is better; the medicine acts well, but keep the iron hot." Then turning to the son I said: "He will be well when the twenty minutes are here, I need stay no longer. It is almost dark, raining hard, and I must start for home at once. But William if it should not cure him perfectly, don't forget the hot iron. Draw it down his back from his neck to his tail." Away I went. I went so quickly, that he might not be restrained by my presence, and that my orders so imperatively given would convince him that he could not escape them.

The next day at ten o'clock I rang the bell, and the mistress opened the door. The moment she saw me she threw her hands above her head and said: "Well, doctor, this beats anything thing I ever did see. You had not been gone more than half an hour before he was down stairs dressed up and went to the barn to do his work."

I forgot to say that before giving him the medicine I said to the son, "Why do you hold him?"

"Why, doctor he would knock his brains, out if we were to let go of him.

"Well," I replied, "They are his own brains, let him knock them out. Let go of him."

They did so, and he began a furious attack on the head board with both fists, but he hurt his knuckles and exhausted himself, and it was after that I gave him the medicine.

But had he been bitten by a dog? They did not know, but they were all convinced that he had hydrophobia. They had had him but a short time and did not know what might have happened him previous to coming to them.

But we have other testimony. The recent deaths of Mrs. Hohman and Elmer Pickering, of Frankford, from alleged hydrophobia resulting from the bite of the same dog, and the opinion of Coroner Ashbridge that no such disease exists, has awakened interest and led some prominent physicians to express themselves on the subject. Dr. Chas. M. Dulles, who has for years made a special study of it said: "Hydrophobia is not a distinct or specific disease. It has no symptoms peculiar to itself. It is really but a combination of the symptoms of many other diseases; and in all the cases I have examined, I have never seen any symptoms which did not belong to other and specific diseases—those of the brain, nervous system or throat. Those who believe in hydrophobia now, are those who believed in witch-craft in the old colonial days. Fear is a very large element of it. It occurs often and flourishes in those places in which it is believed in. See how it is in Paris. People thoroughly believe in it there and have a dread of it, and the result is a large number of cases constantly. What is true of Paris is true of France. The Rhine separates the French from the Germans but a short distance. The Germans do not believe in hydrophobia. They have very few cases in consequence, I believe, of their belief.

"There was a recent case of alleged hydrophobia in this city, in which an eminent specialist on nervous diseases, two regular practitioners and myself were concerned. It was a typical case of hydrophobia; there were all the symptoms popularly supposed to indicate the disease. We performed an autopsy. The person died purely and simply from meningitis located at the base of the brain and the spinal column. Another case with a regular practitioner and myself. It was as regular hydrophobia as I believe anything can be. The patient died. I predicted that lesion of the brain would be found. The autopsy revealed just the conditions I had prophesied, but remained (to others—the public) one of hydrophobia. Another thing. It is very common for the bite of a dog to be cauterized with silver and hypodermic injections of morphine to be resorted to in the later stages. There is no case on record in which these treatments have been used and the patient recovered."

Dr. Charles Mills, the eminent specialist in nervous diseases, said: "I believe that eight cases out of every ten of alleged hydrophobia are not genuine, and I am

not convinced that it is a specific and distinct disease. I have seen several cases and have been concerned in several more, and have participated in three autopsies. Of five cases in which there was every symptom that is coupled with hydrophobia, four were undoubtedly due to other diseases, and possibly the fifth was also. Meningitis and epilepsy enter very largely into the composition of hydrophobia. Imagination also plays a large part. There is a specific nervous disease known as hydrophobia. I now have as a patient, a woman who has long suffered from it. She has most intense horror of dogs, and it is a fact that, although in very good health otherwise, this woman actually remained inside of her house for eleven months, not daring to go out. She could not be induced to do so. A short time ago her husband happened to tell her that a dog had brushed against him as he was walking along a street. The wife's fears developed to such an extent that it was possible to calm her only by destroying the suit that her husband wore when the dog brushed against him as he walked. It seems odd, don't it? But it is perfectly true. The sight of a dog from one of her windows, if his tongue is hanging out, or if there is froth at his mouth, is apt to give her convulsions. Recently she heard that a dog had a fit on Thirteenth street. She at once begged all her family to avoid the locality, as much as possible. Now, if that woman should be bitten by a dog what do you suppose the result would be? How long do you suppose she would live? She would be likely to die of convulsions in 48 hours. I agree perfectly with Dr. Dulles that Pasteur's discoveries and his treatment have done more harm than good."

Of the thousands, yes tens of thousands of persons who are loud in their belief and knowledge—as they call what they have heard about cases—not more than one in a hundred, if one in a thousand, has ever seen a case either of the true or of the spurious disease. So I feel like giving the belief of a coroner who has investigated many cases called hydrophobia, which proved fatal. In the case of Mrs. Hohman, of Frankford, already referred to, a post-mortem of whose body was refused by Coroner Ashbridge, he wrote as follows in defense of his act: "This I refused to do because, from my experience and standpoint, there is no such malady as hydrophobia." In human beings, I suppose he meant. "As it is classed to-day, and for the past year, I have made no post-mortem in such cases, because the results yield nothing, nor does it prove anything in the interest of science, or decide anything definite as to the cause of death. All that has ever been found in post-mortems in the past twelve years *is a congested state of the brain*, and this will be found in all cases of death from convulsions and the like. In the epileptic the symptoms are precisely like those of so-called hydrophobia: frothing at the mouth, rigid jaws and convulsions. I have observed the same things at post-mortems upon persons apparently in previous good health, who have died from nightmare, or horrors; the brain congested in a similar manner. To my mind it is the effect of the mind over the body, producing acute nervous strain and disorder; and as to the blood-poisoning theory, that will not stand investigation. The treatment of Pasteur has few believers. If one would see the symptoms of a person dying in an epileptic fit, and it was said he had been bitten by a dog, it would be at once pronounced the worst case of hydrophobia known."

### Acne.

Dr. Hilles (*Deutsch Med. Woch.*) uses:

℞

| | |
|---|---|
| Sulphur Iodidi ..... | gr. x. |
| Lanolini..... | ℥i. |

M. Sig. Apply twice daily after washing the parts with hot water.

# COMMUNICATIONS.

## OPERATION WOUNDS OF THE THORACIC DUCT IN THE NECK, WITH A RÉSUMÉ OF THE TWO PRIOR RECORDED CASES AND TWO ADDITIONAL CASES.*

W. W. KEEN,† M. D.

When we consider the frequency with which operations are done on the left side of the neck in the vicinity of the junction of the jugular and subclavian veins for the removal of enlarged glands, for tumors, for goitre, etc., and of stab and other wounds, it is surprising that there are not a number of instances of wounds of the thoracic duct. The danger of wounding it may be greatly increased by the fact that Dieterich (Henle's *Anatomy*, 1876, iii. 453) has found the arch of the duct as much as 5½ cm. (over two inches) above the top of the sternum and touching the thyroid gland. Yet so far as my investigations have gone, I have only been able to discover two cases of wound of the cervical portion of the duct reported in surgical literature. To these to-night I add two more, one of my own, and another, the notes of which have been kindly furnished me by Dr. A. M. Phelps, of New York.

Even in war, wounds of the duct in any part of its course are practically unknown. In neither the Italian war of 1859, the Crimean war, nor our own late civil war, is there a single instance recorded.

CASE I. (Cheever's case.)—Dr. Cheever reports in the *Boston Medical and Surgical Journal* for 1875, p. 422, the case of a tumor of the neck, during the removal of which "the subclavian vein and a large vessel near the internal jugular were both wounded. The distended veins mixed up with the friable glandular growth gave way repeatedly under the forceps and ligature. At this time occurred a new source of difficulty. A transparent, viscid, coagulable, and colorless fluid ran out from the tumor and from the lower corner of the wound in quantities as large as an ounce at a time, some six separate times. Together with the dark venous blood, this fluid constantly obscured and filled the bottom of the neck whenever pressure by the finger or sponges were taken off." The inner two-thirds of the clavicle were then removed. "The subclavian artery was sought and pushed aside and an aneurism-needle passed between it and the vein, first out toward the shoulder and a ligature tied; and second, close to the sterno-clavicular articulation, where the needle and ligatures surrounded the venous trunks at or upon their junction in the left vena innominata. The artery was not wounded nor tied. All bleeding now ceased, but the transparent fluid still oozed out moderately. The wound was lightly packed with sponges and ferric alum; no hemorrhage occurred, and the transparent fluid did not soak through the sponges." The patient died from shock and exhaustion, thirty-six hours after the operation. "No formal autopsy was made, but an examination of the wound showed the subclavian vein tied externally, and also at the junction of the internal jugular and subclavian. The remains of the tumor extended two inches below the clavicle, but were enucleated without piercing the pleura. This fragment of tumor had incorporated into itself several venous trunks or sinuses caught and entangled in the gradual agglomeration of glands. There was no opening into the pleura, no sac running down into the thorax or axilla, no cyst in any direction. The source of the transparent effusion could not be traced. There would seem to be but little doubt that this fluid was lymph from a large branch of the lymphatics in the tumor, or more probably from the thoracic duct where it arches over to join the left subclavian vein. In contact with, if not surrounded by, the glandular enlargement, its thin and transparent walls were readily wounded in trying to remove the lower part of the tumor. No other source for the clear fluid could be found, there being neither cyst, hydrocele of the neck, nor pleural effusion to account for it. The

*Read before Philadelphia Academy of Surgery, April 2, 1894.

†Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, etc., Philadelphia.

fluid under the microscope exhibited no cells save a few stray blood corpuscles. The patient having fasted for twelve hours before the operation, there would be little, if any, of the milky emulsion of chyle in the duct.

"The fluid poured out of this wound coagulated after contact with the air in a firm jelly, just as blood coagulates. This no doubt was due to its fibrin. Its large quantity pointed to a considerable duct as its source, although it must be borne in mind that the whole lymphatic system of the neck was probably vastly enlarged, and secreted great quantities of lymph. Very probably the waste of nutritive plasma by this leakage of lymph in the wound hastened the exhaustion of the patient, and, if due to a wound in the thoracic duct, would have precluded his recovery."

CASE II. (Boegehold's case, *Arch. f. klin. Chir.*, 1893, vol. xxix. p. 443.)—In March, 1880, Wilms extirpated a tumor as large as a fist from the left side of the neck of a stout man forty-five years of age. In the course of the operation Wilms gradually neared the junction of the subclavian and jugular veins. As he was carefully scraping the tissue with a sharp spoon, suddenly there poured out over the operation field a stream of whitish fluid the diameter of a straw, which mingled with the rather freely flowing blood. This fluid could not well be anything else than chyle, for a wounded lymph vessel would have given exit to a clear, or at the most a slightly yellowish, but not whitish, fluid. There was no abscess nor any purulent pleurisy. After this wound of the thoracic duct, the extirpation of the tumor was terminated at once. The milky fluid no longer escaped, and on account of the considerable hemorrhage the idea of securing it in the depth of the wound was abandoned. The wound was then packed with salicylic wool and an antiseptic bandage applied. The packing was removed the next day without any further appearance of the chyle. The patient recovered without incident, and six months afterward died, presumably from pulmonary metastasis of the carcinoma.

CASE III. (Case of Dr. A. M. Phelps, of New York; personal communication.)—June 4, 1893, at the Mary Fletcher Hospital, Burlington, Vt., Dr. Phelps operated on a malignant tumor of the left side of the neck. "It was found that the jugular vein passed through the tumor, and this necessited the removal of three inches of the jugular, near its junction with the subclavian. The tumor extended downward underneath the subclavian vein and involved the deep muscles of the neck. The wound was dressed four days later. There had been a constant profuse discharge, which at first was supposed to be serum, but its color, like that of skimmed milk, and its source from a single point in the wound, as well as its quantity, soon forbade that presumption. I estimate that about three pints a day had been lost. It was sufficient to saturate daily ten or fifteen ordinary bed-sheets folded in a number of thicknesses, in addition to saturating the surgical dressings. The man was rapidly losing flesh. A consultation of staff was held on June 11th, and the consensus of opinion was that the thoracic duct had been severed. The point of a probe the size of a large knitting-needle inserted at the point of evacuation entirely stopped the discharge. The point from which the liquid issued was caught by forceps, which were allowed to remain in place three days. The patient gained a pound a day after the discharge was stopped, and made an excellent recovery."

The duct cut, in his opinion, was one of the divisions or ramifications of the thoracic duct, but the staff thought that the main trunk had been severed.

The fourth case is my own.

CASE IV.—Miss S., aged twenty years, was first brought to me in November, 1892, by Dr. Melcher, of Mt. Holly, N. J. There was a small enlarged gland on the left side of her neck above the clavicle, a scar at a corresponding point on the right side, and another scar at the upper border of the right breast. From these two places showing scars, Dr. Melcher had removed glands which were undoubtedly tubercular. Just below the right clavicle and a little external to its centre was a tumor, evidently deep in the apex of the right axilla, firmly attached so as to be practically immovable, and extending, so far as could be ascertained, half way or more from the clavicle to the axillary border. It first appeared about a year ago. I judged it to be a series of enlarged glands, probably attached to the vessels. She had occasionally tingling and numbness in the right arm, and slight œdematous

swelling. Soon after she was here Dr. Melcher made an attempt to remove the tumor, but the hemorrhage was so great as to deter him, and he closed the wound, from which she made a good recovery.

Operation, Jefferson Hospital, January 28, 1893. I made an incision almost vertically in the axis of the body, from the clavicle about four inches downward. I came upon the tumor as soon as I was through the great pectoral muscle. Finding its extent, especially toward the axilla, greater than it appeared from the outside, I made two transverse incisions, converting the whole incision into a cross. I first dissected from the clavicle downward. I found the tumor adherent, not to the clavicle, but to the second rib and the costo-coracoid membrane. With a good deal of care and difficulty I was able to separate the upper border of the tumor from the clavicle and work my way downward and also outward toward the vessels. In a few moments I saw a part of the tissue collapse with inspiration, and I recognized that this was the subclavian vein.

I was finally able to remove the entire tumor, but only after one of the most difficult and tedious dissections I ever made. The tumor was a mass of enlarged glands extending three quarters of the way around the axillary vessels, the upper border alone being free. It was with the greatest difficulty that I could separate the tumor from the vein to which it was especially adherent, but I finally succeeded. The dissection took over an hour and the whole operation was nearly an hour and a half long. I button-holed the axillary skin at its posterior border and carried out a drainage-tube, otherwise closing the wound and dressing it as usual. The hemorrhage was moderate, not over eight or ten vessels requiring ligation.

February 11, 1893. Her recovery was rapid and gratifying. The highest temperature was 99.8°. The drainage-tube was removed in forty-eight hours, and the sutures on the third, fifth, and seventh days. On the eighth day she went home perfectly well.

Dr. Kyle reported as follows on the specimen: "Frozen sections from this specimen showed it to be tubercular. The sections were so arranged as to include portions of dense tissue, also the caseous mass. Macroscopically and on cutting through the specimen it resembled lymphosarcoma, which appearance could be produced by the enlargement of the gland, which would cause pressure on intervening tissue, giving it that peculiar fibrous appearance. By the methyl violet and blue stain the tubercular condition was easily recognized."

She returned to me December 12, 1893, with enlarged glands in the neck on both sides, just above the clavicles and in both axillæ, especially the right one. These glands were high up in the axilla on both sides and were apparently (especially on the right side) very adherent. In the neck the glands were rather peculiar, in that while they were very perceptible as tolerably large, nodular masses, evidently composed of a number of glands, the inner portion on both sides was soft, markedly lobular, and apparently contained some fluid. Those on the left side of the neck were larger and gave her a good deal of annoyance and pain, somewhat resembling in this respect those in the right axilla. I advised her therefore to have them removed.

Operation, Jefferson College Hospital, December 15, 1893. Present, Prof. Clayton Parkhill, of Denver, and Drs. Hearn and William J. Taylor. Drs. J. Chalmers Da Costa and Weaver assisted me. When the patient was etherized and recumbent, I saw a marked change in the condition of all the tumors. The one in the left axilla just below the clavicle could not be found. That on the right side was apparently very much diminished, as were both of those in the neck, the right one being partially perceptible and the left moderately so. The soft, fluid part of the cervical swellings had entirely disappeared.

The right axilla was opened by an incision passing along the border of the tendon of the great pectoral muscle. The operation was tedious and very difficult mechanically, by reason of the extensive and very dense adhesions from the periadenitis and from the former operations. The adhesion to the axillary vein was particularly solid and sometimes was almost as tough as though they had been made of leather. However, after very slow, careful, and patient dissection I was able to get out a large mass of glands.

Having finished the dissection of the glands in the right axilla, I next made an

incision above the left clavicle to remove the glands there. There was a great deal of periadenitis, creating very firm adhesions, especially downward and inward toward the junction of the left internal jugular and subclavian veins, both of which were laid bare nearly, but not to their junction. I was carefully dissecting these adhesions away with Allis's blunt dissector, when suddenly I made a small opening in what was apparently an adhesion, and instantly there welled out from it a perfectly limpid fluid. At first I thought I had opened a cyst; but, on observing that the fluid escaped continuously and with a very evident respiratory rhythm, and that the fluid apparently flowed from a tear one-fourth of an inch in length, from a tube about one-eighth of an inch in diameter, it occurred to me that it was either one of the dilated left lymphatic ducts just before their entrance into the thoracic duct, or that, more likely, it was the thoracic duct itself. About two ounces of fluid escaped in all. I sucked up a little of it with a hypodermatic syringe. It coagulated in a few minutes. Dr. Da Costa suggested that the distinction between the two fluids, *i. e.*, from the lymphatic and the thoracic ducts, could be made by the fact that the fluid in the thoracic duct should be milky, but as she had taken no food since the previous evening (eighteen hours) this gave no help. Against its being the thoracic duct was the fact that it was just behind the upper border of the clavicle and, therefore, lay too high for the thoracic duct; but as the glands were being dragged upward, this objection I felt was not valid. Also, although I could introduce a grooved director into the tube from which the fluid was escaping, the director only entered about one-half to three-quarters of an inch when it met some obstacle. In such a locality and in such a novel experience, I did not care to enlarge the boundaries of science at the possible expense of my patient, and hence I decided to desist from further exploration and remedy the apparent mischief at once. Accordingly I closed the opening by the pressure of one finger, and carefully removed the glands, which were almost entirely loosened at the moment of the accident. Then I seized the two edges of the opening with forceps, and by means of the finest Hagedorn semi-circular needle and fine silk I closed the wound. Some little leakage still took place. There was also a little of a similar fluid from the upper part of the wound, but it seemed a general oozing rather than from any distinct vessel. The remainder of the operation was completed with ease, although it was extraordinary what a large mass of glands I removed, in view of the almost utter inability to perceive them when she was etherized and recumbent. Nothing was found to account for the soft and apparently fluid part of the tumor noticed when she was first examined. This soft mass was at least one and one-half inches external to the site of the opening into the thoracic duct and nearly as much above it.

A drainage-tube was inserted into the wound, but was removed after five hours, having served its function of conducting off most of the bloody wound-fluids, and I feared that its retention would be followed by a lymphatic fistula. Any escape of lymphatic fluid from the thoracic duct I thought should be repressed as quickly as possible by absolute closure of the wound. During the five hours the amount of wound-fluids was very large for so small a wound, amounting to nearly a pint, and its light color showed that the small amount of blood was diluted with a great deal of clear fluid. The dressing the next day was partially saturated by probably an ounce or two, and after that was dry.

On the eighth day after the operation, having made an absolutely uneventful recovery, she went home. Not the slightest evidence of trouble appeared in the wound in the neck, neither swelling, redness, nor pain. Her weight on December 11th, four days before the operation, was 106 pounds and eight days after it, in about the same clothing, 103 pounds. Her highest temperature was 99.8°, on the evening of the operation. The following table shows her weight since the operation:

| | Weight. |
|---|---|
| December 28, 1893 | 100 pounds. |
| January 6, 1894 | 101 " |
| " 12, " | 100½ " |
| " 19, " | 100¾ " |
| " 26, " | 100¾ " |

March 15, 1894, same weight; her cough troubles her considerably.

Dr. Kyle reported that in the fluid there were many lymphocytes or lymph-corpuscles of different sizes; some few were slightly granular, and there were many fat or oil-globules, small in size, but large in number. The macroscopic appearance of the fluid was slightly opaque.

Remarks.—First. The anatomy of the thoracic duct. As has been shown here to-night in the beautiful dissections of Mr. Ward Brinton, the thoracic duct does not always empty by a single mouth at the junction of the left jugular and subclavian, but is apt sometimes to break up into two or three ducts or even into a delta, some of the branches emptying into each of these large veins, and, as Dr. Phelps finds from his dissections of the duct, into other deep veins of the neck. Verneuil (*Le Système Veineux,* 1853) states that Boullard in twenty-four cases found it to empty by one mouth eighteen times, by two mouths three times, by three mouths twice, and finally once by six mouths, of which two opened into the subclavian, two into the jugular, and one each into the external jugular and the vertebral veins. Lacauchie (Henle, *l. c.*) gives an instance of four terminal canals. In twenty-one injections of the duct Boegehold found that in two cases it divided at its anastomosis with the veins into three or four branches, and in one case, about two inches before its termination, a branch as large as a straw passed to the subclavian, the main trunk emptying at the angle between the subclavian and the jugular. It is, therefore, possible in all these cases of wound that not the main trunk, but one of these branches—perhaps, as in Boegehold's case, a branch as large as a straw—was injured. Bayford (Boegehold, p. 447) records one case of dislocation of the thoracic duct from a curvature of the spine, which might increase materially the possibility of its being wounded should an operation have to be done in such a case. Boegehold (p. 455) also quotes a case from Scherb of the partial obstruction of the duct by a calculus. The occasional great height of the final curve of the duct in the neck has already been mentioned.

Secondly. The character of the fluid. There could be no possibility that the source of the fluid was other than the thoracic duct in Boegehold's and Phelps's cases, as, from its milky color, the fluid was evidently chyle. In the other two cases the fluid has been so clear that it resembled serum. I do not know the relation of the hour of operation to the hour of the last meal in Cheever's case. In my own case the patient, having had two prior operations, and suffering from ether nausea, had refused to eat any breakfast whatever, and when I operated, at twelve o'clock noon, it was eighteen hours since she had eaten the previous meal. The quantity of the fluid in Phelps's case was very extraordinary, and leaves no doubt that it could only have been from the thoracic duct. In Cheever's case and my own the quantity and character of the fluid make it reasonably certain that it was from the duct, but it is not so demonstrably sure as in the other two cases.

Third. Treatment. Cheever's case was so speedily fatal from other reasons that no inferences can be drawn from it. In Boegehold's case packing was sufficient to arrest the flow and the patient recovered. In Phelps's case pressure-forceps arrested it entirely. In my own case the suture of the vessel was perfectly feasible, and the result was most satisfactory. It seems to me clear that if this procedure can be adopted it should always be done. I very anxiously watched the weight of my patient from week to week for the first few weeks after the operation. Then, finding that she was not losing ground, it was clear to me that she had permanently recovered from the accident, which at first caused me much anxiety.

Fourth. Experimental researches. Boegehold, so far as I know, is the only one who has tested the question by experiment. In his first two experiments, in dogs, he exposed the thoracic duct at its entrance into the veins and wounded it with scissors. Pneumothorax followed, but disappeared within five days. Eight days after the accident the dogs were killed. No trace of pleurisy was found, and the duct at the level of the fourth dorsal vertebra was surrounded with a thin whitish-red clot of fibrin. The duct was divided for over one-fourth of its circumference. In the next three experiments the duct was cut obliquely. On the following day the dogs were evidently sick, with a rapidly increasing frequency of respiration. On the evening of the third or fourth day they died, and at the autopsy the pleural cavity was found full of chyle. The cause of death was compression of the heart and lung from effusion of chyle. In the sixth and seventh experiments he placed a canula in the duct. This was followed by suppurative pleurisy, with death respectively on the fourteenth and tenth days. At the autopsy the pleura was found covered with fibrinous clots, but as the fever had sub-

sided on the fifth day, he ascribed death to the loss of chyle. In the eighth experiment he ligated the ends of the duct in the neck. On the fourth day he inserted his finger into the pleural cavity. The duct was easily found as it was distended with chyle. He wounded it slightly with scissors, and seventy-two hours later the dog was killed. The duct and the receptacular were distended with chyle, and at the site of the wound a small red fibrinous clot was found. Very little chyle had escaped on account of the smallness of the wound.

As a result of his experience he thinks that the complete integrity of the duct for the support of life is not absolutely necessary. He gives a number of instances of complete obliteration or compression of the duct without any symptoms. The collateral circulation of the lymph seemed to be established, and Schmidt and Mulheim have shown experimentally that the closure of the duct in dogs, in whom the canal is always single, did not affect either the digestion or the absorption of albuminous matter. An injury followed by closure of the duct, therefore, is not necessarily fatal. The danger is that if the duct is not closed, either compression of the lungs and heart from the constantly augmenting accumulation of chyle in the pleural cavity will prove fatal, or that the loss of nourishment will be lehtal if it escapes externally. Wounds of the duct seem to be entirely capable of healing. Should the heart and lungs be compressed, clearly the pleural cavity should be opened in order to avoid the immediate danger of death from compression, as is shown by Kirchner's case (*Arch. f. klin. Chir.*, 1885, p. 156). This seems to have been an undoubted and severe rupture of the thoracic duct within the thorax, and yet was followed by recovery. It shows that even rupture of the duct may not necessarily be fatal.

A little girl, nine years of age, healthy although not very strong, was pushed violenty against a window-sill, injuring her at the level of the third rib. Marked orthopnœa, with cyanosis and sweating, and dilatation of the nostrils followed in the course of two weeks. The right half of the thorax was broader than the left up to the level of the spine of the scapula and the third rib. The heart pushed to the left, and the liver extended two fingers' breadth below the border of the ribs. The temperature was normal. The right chest was punctured in the fifth intercostal space and a litre of fluid resembling milk was poured out. Examination by the microscope showed undoubtedly that it was chyle. Ten days later the dyspnœa was so great that puncture was again contemplatad, but under warm baths and slight purgation by senna the improvement was such that puncture was not done a second time, and complete recovery followed. In six months the child was better than prior to the attack.

Kirchner states that, even including some uncertain cases, there are but seventeen on record of injury of the thoracic duct, either in the neck, chest, or abdomen; six resulting in chylous ascites; nine in chylo-thorax; one of hydrops lacteus from the collection of lymph in the mediastinum; and finally, the case of Boegehold, the only instance he gives of injury in the neck. The three additional cases I have reported here bring the total number up to twenty, and of wounds in the neck alone to four.

Busey (*Trans. Assoc. Amer. Phys.*, 1889, vol. iv. p. 76) refers to a number of cases of injury to peripheral lymphatics by bleeding, etc., and also the effusion of chyle into the thorax, abdomen, tunica veginalis testis, etc. In the discussion Welch said: "I do not think that the mere occlusion of the thoracic duct, still less obstruction to the venous flow in the subclavian veins, is followed by serious interference with the flow of lymph and chyle. I have found the thoracic duct completely occluded by a tuberculous thrombus in a case of acute miliary tuberculosis without any such effect."

The pressure in the thoracic duct is not very high. According to Weiss, in the neck it reaches from 9 to 15 mm. of mercury.

A RUSSIAN scientist has succeeded in tracing all man's disease to the fact that he wears clothes.

# TRANSLATIONS.

## A RARE CASE OF SPONTANEOUS GANGRENE.†

Dr. Zeller reports the case of a chlorotic patient, aged 20, who had experienced pain and weakness in the joints of the right arm for the past year; this was followed by tingling sensations in the hand and bluish discolorations of the finger tips. These manifestations were at times accompanied by a complete loss of sensation. One of these attacks was followed by necrosis of the fingers of the right hand, extending to their middle joints, and necessitated amputation. The arteries did not spurt when cut. Angiospastic gangrene was diagnosed, there being an absence of any other etiological factors.—*Berliner Klin. Wochen.*, 1893, No. 52.

—W.

## THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

### CHRONIC CONSTIPATION.

The (*Gazzetta Medica di Roma*, No. 5, 1894) advises the following preparation in chronic constipation:

℞

| | | | |
|---|---|---|---|
| Aloes | o | 25 | (grs. iv). |
| Sulphate Strychnine | o | 015 | (gr. ¼). |
| Extr. Belladonna | o | 09 | (gr. j ½). |
| Powdered Ipecac | o | 35 | (grs. vss). |

Sufficient for twelve pills. One every evening.

### IRRITABLE BLADDER.

Dr. W. Chun (*Le Progrès Médical*, No. 11, 1894) speaks highly of the following formula in irritable bladder-polakiuria:

℞

| | | | |
|---|---|---|---|
| Benzoic Acid | 4 | o | (3j). |
| Borax | 6 | o | (3jss). |
| Water | 180 | o | (3vss). |

A soupspoonful three times a day.

This mixture will rapidly quiet the desire to urinate so frequently especially when it is due to an excess of phosphates in the urine.

### A LOCAL APPLICATION FOR UTERINE CANCER.

Dr. Lucas (*Le Progrès Médical*, No. 11, 1894) advises after the diseased surface has been carefully cleaned, local application of the following powder:

℞

Powdered Benzoin.
Powdered Iodoform.
Carbonate Magnesia.....āā 1.0-2.0 (grs. xv-xxx).

It diminishes the fetid discharge and prevents ulcerations around the vulva and perineum.

### ABSCESSES AND ULCERS OF THE CORNEA.

Prof. de Wecker (*Rivista Clinica E Terapeutica*, No. 2, 1894) claims that the modern rational treatment of ulcers and ulcerating abscesses of the cornea should consist of curetting the ulcer with a small and sharp curette with antiseptic irrigation. There is no destruction of healthy tissues as with the cautery. The remaining corneal lesion will rapidly heal without reinfection under an occlusive antiseptic bandage. After curetting it is necessary to irrigate the cornea with an antiseptic solution for some time in order to insure perfect asepsis. He proceeds as follows: With a small sharp curette the ulcer or abscess is scraped until all the white portions are detached, then profuse and prolonged irrigation with a 4 per cent. boric acid solution, and finally, an occlusive bandage.

### INJECTIONS OF ARTIFICIAL SERUM IN NEURASTHENIA.

Dr. Cheron (*Revista Medica de Bogotá*, February 15, 1894) claims to have obtained beneficial results in the treatment of neurasthenia with hypodermic injections of an artificial urine prepared after the following formula:

℞

| | | | |
|---|---|---|---|
| Chem. Pure Sulphate Soda. | 10 | o | (3ijss). |
| Chem. Pure Phosphate Soda | 5 | o | (3j¼). |
| Chem. Pure Chloride Soda. | 2 | o | (grs. xxx). |
| Crystall. Carbol. Acid | 1 | o | (grs. xv). |
| Distilled (boiled) Water | 100 | o | (3iijss). |

Inject five to ten grams (3j¼-3ijss) of this solution every day or every third day.

ISSUED EVERY SATURDAY

Address care P. O. Box 843, Philadelphia, Pa.

HAROLD H. KYNETT, A. M., M. D.
Editor

RODERIC C. PENFIELD
Publisher

147-149-151 North Tenth Street, Philadelphia

TERMS:—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 12, 1894.

## EDITORIAL.

### THE D. HAYES AGNEW MEMORIAL.

When the REPORTER was called upon to chronicle the death of this great surgeon, it expressed the hope that "by the right of great powers and many virtues, and the beneficent uses made of them, Dr. Agnew's memory should be secured to other generations than that to which he belonged. He did too much for those among whom he lived and to whom he rendered unselfish service, for them, without discredit, to fail to build some tribute to his memory—something to further the great causes to which he devoted all the energies of his mental and moral faculties; something typical of his noble example, of the purity and courage of his life, of his unselfishness to his profession and to humanity."

"Hundreds of public-spirited men, who knew and loved Dr. Agnew in life and appreciated the stalwart manliness of his character, have a common interest and pride in his name and fame. It would be their pleasure, and duty as well, to aid such a work of love, honor and gratitude."

This hope seems now about to be realized and it is a pleasure to the REPORTER to give endorsement to the following:

The D. Hayes Agnew Memorial Committee, organized a year ago to secure a lasting memorial of Dr. Agnew in connection with the University Hospital, have pleasure in reporting that subscriptions have been promised of sufficient amount to give reasonable assurance of the speedy and successful carrying out of the project.

The plan includes not only the Children's Ward (for the building of which this Associate Committee was established and for which it is so earnestly laboring), but also an amphitheatre and ward class rooms, with wards for men and for women,—the whole to be a model in perfection of details and completeness of appliances, and thus a fitting representation of the wonderfully full and complete work of Dr. Agnew.

The State Legislature, at its last session, made an appropriation of $80,000 to the University Hospital for building purposes, provided that an equal sum of $80,-

000 be raised by the friends of the Hospital, and paid in cash, available for construction purposes. The Managers of the Hospital, appreciating the eminent propriety of our movement, have consented to give to the entire wing the honored name of D. Hayes Agnew.

Toward the additional $80,000 to be so raised, about $60,000 can now be counted upon as available in cash on or before May 1, 1894, leaving only about $20,000 more to be secured by that time, so that building operations may begin this spring, and the State appropriation be drawn and expended within the two years contemplated in the Act.

It is to be hoped that, in addition to the building fund, there may also be secured a sum sufficient for the beginning of an endowment. Such a memorial will best attest the affection inspired by Dr. Agnew's life of usefulness and the example of devotion to his profession, both as teacher and practitioner.

The grant by the Legislature is a recognition of the work done by the University and its Hospital, to which Dr. Agnew gave the best years of his busy life, and the subscription supplementing and securing that appropriation will show how his many friends, patients and students honor his memory.

All those who desire to join in this memorial of a great surgeon and good man can do so by sending their subscriptions to the Treasurer, Mr. Eugene Delano, of Messrs. Brown Brothers, at the banking house, southeast corner of Fourth and Chestnut Streets, Philadelphia.

By order of the Committee.

J. S. MacIntosh, D.D.,
*Chairman.*

J. G. Rosengarten,
*Secretary.*

Wm. Pepper, M.D.,
*Provost of the University.*

## THE MEETING OF THE STATE MEDICAL SOCIETY.

The ensuing week will be one of much interest to the medical profession of this state, as it will witness the annual session of the State Medical Society of Pennsylvania. The meeting this year was to have been held at Gettysburg, but circumstances compelled a change of place and the State Society accepted the invitation extended by the Philadelphia profession to become its guest.

Aside from the interest and importance of the meeting as a scientific body, preparations have been completed for the social entertainment of the visiting members and their friends. In addition to the usual courtesies, arrangements have been made for a theatre party, to be followed by refreshments, on the evening of Thursday, May 17th. The play will be "The Princess Bonnie" at the Chestnut Street Theatre.

Efforts are being made to enable the delegates of the State Society to accept an invitation extended by the Mayor and citizens of Asbury Park, N. J., to visit that famous resort and enjoy its hospitalties.

A year ago, at the suggestion of the Reporter, the citizens of Asbury Park extended an invitation to the American Medical Association to hold its meeting of 1894 at that place, and accompanied their invitation by a guarantee of remarkable inducements, but the Association accepted the invitation to the Pacific coast.

At the request of the Reporter, Asbury Park will again extend the invitation for the meeting of the Association for 1895, and the present invitation to the State Medical Society is to enable its members, and especially those who are to attend the San Francisco meeting, to see for themselves the superior attractions and facilities possessed by Asbury Park.

The Reporter would be glad to see such of its friends as may find time to visit its offices during their stay in the city.

# ABSTRACTS.

## OUR PRESENT KNOWLEDGE OF THE CURE OF MALARIA BY MEANS OF QUININE.

Professor C. Binz (*Cent. f. die Med. Wissen.*) states that just twenty-six years ago he opposed, in the pages of the *Centralblatt*, the then generally-accepted theory that the curative action of quinine in malaria is developed through the nervous system, and propounded the theory that quinine in all probability acts as a protoplasm poison on the pathogenic micro-organism, at that time undiscovered, which is at the root of all paludism. It has now been discovered that all forms of malarial fever are brought about by organism of the genus amœba, which penetrate the bodies of the red blood-cells, at whose expense they increase in size, finally sporulating and destroying their host. Laveran, who first discovered and described the parasite of tertian ague, also investigated the action of quinine on that organism, and found that when microscopical preparations of the parasite were treated with quinine, the vitality of the disease-germ was speedily destroyed, a fact which has been substantiated by Marchiafava, Celli, Grassi, and Feletti. The influence of quinine on the malaria parasites has also been studied by examining the blood of malaria patients before and after the exhibition of the drug. In this instance the investigations of Laveran, Romanoffsky, Bacelli, Golgi, Marchiafava, and Bignani established the fact that the parasites were killed by the quinine absorbed into the blood.

Dr. Mannaberg, who has recently investigated this question in the malarial districts of Dalmatia, Istria, etc., finds, among other things, that about three hours after the exhibition of from 7 to 15 grains of quinine, the amœboid movements of the amœboid form of the parasite of tertian ague slacken to a very perceptible degree, and that after a lapse of a further period of three to six hours, the number of parasites in the blood of the patient greatly diminishes, while many of those still left are torn and mutilated. On the full-grown parasite of tertian ague quinine either produces a complete cessation of all movement in the pigment, whereby the parasite acquires a glittering, cloddy appearance, as though coagulation had set in, or else dropsical swelling is set ), or, finally the parasite falls to pieces. Shortly after the exhibition of quinine, medium-sized parasites of tertian ague develop intense activity. It appears that quinine possesses a stimulating action before causing coagulation and immobility. This phenomenon has also been observed by Bacelli. According to Golgi, the medium-sized parasites of quartan fever acquire a glittering appearance and tendency to shrivel when the patient receives quinine internally; the large forms, however, become distended, their pigment exhibits lively oscillatory movements, and they frequently contain vacuolæ or abortive spores.

About three hours after the exhibition of a dose of 7½ grains of quinine, the nucleoli of some of the amœbæ of the milder forms of true quartan had either partially or entirely lost their tinctorial characteristics. After twelve hours of the treatment stainable nucleoli were hardly met with at all, most of the parasites having broken up into irregular fragments.

In those forms of malaria which are not curable by quinine that drug has no effect whatever on the parasites present in the blood. Bacelli, however, has found that many such severe forms which defy the ordinary method of treatment may be speedily cured by injecting the usual dose of quinine into a vein.

In spite of certain differences on minor points, Mannaberg and the other investigators one and all agree that quinine is a direct poison for the malaria parasite, and that the therapeutic doses employed are non-injurious to the cells of the human organism. Any assistance from the nervous system in the process of cure is neither evident nor necessary.

With regard to the prophylactic action of quinine, it is to be noted that the drug disappears very gradually from the blood and in an almost unaltered condition. By this means any young amœbæ and spores are kept in constant contact with the drug and are thereby checked in their further development. As to the part played by the leucocytes, it appears that phagocytism is prominent in cases of spontaneous cure of malaria, but not when quinine is employed. — *Provincial Medical Journal.*

## THE NECESSITY OF PROMPT TREATMENT OF TUMORS OF THE BREAST.

(H. R. Coston, M. D., in *Va. Med. Mo.*) The frequency with which one meets cases of cancer of the breast in its various forms is ample excuse for occasionally calling attention to its relief. During the last few months two cases have fallen under my observation which strikingly illustrate the necessity of more care on the part of physicians in dealing with cases of "tumors in the breast."

A tumor situated anywhere in this gland should always be looked upon with suspicion. However small it may be, it does not relieve doubt of its malignancy. Although not larger than a split pea, it may be the beginning of a slow and painful death if not promptly and vigorously treated.

Carcinoma is regarded by most authorities at the present day as primarily a local disease. Remembering that 90 per cent. of all tumors of the breast are malignant, how imperative it is that the family physician be prepared to give the family and patient the proper advice.

Let us see what a few of the recognized authorities on this subject have to say in regard to the treatment of such cases.

Treves (Operative Surgery) says only 5 per cent. die of the operation.

Gerster says the large number of relapses and high death rate are due to the tardiness of the family physician in advising operation, and the failure of the patient to heed the advice.

His mortality has only been 3 per cent. after operations for the removal of the breast (*Aseptic and Antiseptic Surgery*).

Again, hear this: "The greatest physical evil which can befall a human being is to become infected with malignant disease. * * * The rule should be held imperative that all cases which, after a short trial of remedies, still remains doubtful, should at once be subjected to the knife."—Holmes' *System Surgery,* Vol. III, page 709.

A tumor of the breast occurring after the thirtieth year in either sex, should be excised as soon as discovered.

Gross had a mortality of only 3.7 per cent. of all cases operated, although he often removed large portions of the pectoralis major muscles along with the gland. He has an absolute cure in 21 per cent. of *all* cases.—*Am. Sys. Sur.*, Vol. II, page 319.

The treatment of cancer can only be undertaken by the surgeon since, up to the present time, all the specifics introduced, either by regular practitioners or by charlatans, have proved quite inefficient, if not harmful.—Quain *Dic. of Med.*, page 104.

Thomas Bryant, of London, has a mortality of only 6.7 per cent., and only 3 per cent. of the whole were attributable to the operation.—*Surgery*, page 778.

J. D. Bryant says 9 per cent. never have a recurrence, and an average of one year is added to the life of cases in which there is a recurrence.—*Oper. Surg.*, page 480.

The above are sufficient quotations to show what the present opinions of men, whose ability cannot be questioned, are. And they also show what the prognosis is, both as regards the immediate effect and the prognosis as regards a return of the disease. I could go on citing authors *ad infinitum,* but it is useless. With the present lights before us, no one should hestiate, when a case of tumors of the breast is presented to him, to immediately recommend its removal.

But there are many who, notwithstanding all this, hold up their hands in holy horror and say: "Keep your hands off that lump." A case in point I have now under obsetvation.

Mrs. W., aged 34, came to me two years ago with tumors the size of a hen's egg in each breast. I immediately recommended their removal, together with the axillary glands, which were then becoming enlarged. The woman was willing and anxious for an operation, but the husband objected, and said they would go home and "write" me about it. That was the last I heard of the case until a few weeks ago I was asked to see her, when the case was simply hopeless from extension and systemic infection. It then developed that the family physician had urged them to have nothing done.

A second case just similar has just died and left a houseful of little children to be reared motherless.

Now, in such cases, what a responsibility the family physician takes upon himself when he says: "Have nothing done to that tumor." Take the first case; two years and more have elapsed since the woman first presented herself for operation. It was then, without doubt, a local disease, and thorough removal would have freed her from the disease, and saved her a slow, painful death. We all know that it is *always* a fatal disease without operation; and even should only 9 per cent. have a perfect recovery, it is just nine out of every hundred cases saved from a most loathsome disease and slow and exceedingly painful death. But it is unfair to make 9 per cent. the standard, for there are those who have a perfect result—namely, never a recurrence—in 21 per cent. of all their cases.—(Gross *loc.cit.*) In the event that the disease should recur, we have shortened the stage of ulceration by so much time as may elapse between the operation and its recurrence. Even this is a great gain, as it relieves the mind for a certain length of time and saves the patient and friends much mental worry.

Should the tumor be one of benign nature, no harm would be done the woman, and she would be saved the risk of its degenerating into one malignant in nature.

To sum up, we may say: *Every* tumor developing in the breast in either sex, at whatever age, should be at once extirpated and the glands of the axilla removed with the breast and pectoralis major in cases of extended disease.

The *facts* should be set before the patient in a truthful manner, neither exaggerating the hope of an absolute cure or the immediate dangers of the operation.

## ACUTE MUSCULAR ATROPHY OF THE SHOULDER FOLLOWING A TRAUMATIC INJURY TO THE CRANIUM.*

Dr. V. Idzinski reports (*Wiener Med. Presse*, No. 52, 1893): The patient, aged 24, soldier, received an injury to the skull in the right parietal region; the bone had not been exposed. Two weeks later he noticed a decided weakening of the left shoulder, which increased rapidly and necessitated his admission to the hospital some weeks later. An examination showed a marked atrophy of all the muscles of the left shoulder—sensation, pressure, or temperature unimpaired.

Sensation for pain normal, skin and muscle reflex unimpaired; at no place painful spots.

The author diagnosed the case one of cerebral atrophy, which he based upon the following conditions present:

1. Anatomically—the injury was in the region of the motor centres and corresponds to the right sulcus centralis.

2. The atrophy developed in this region and followed the laws adopted, by extending to the left side, or opposite side.

3. The diagnosis was verified by exclusion of all other diseases.

Anatomically, the author believes that a molecular change took place in the brain substance as a result of the injury.—*Centralb. f. Chirurg.*, No. 8, 1894. W.

# SOCIETY REPORTS.

## THE CLINICAL SOCIETY OF LOUISVILLE.

*February 13, 1894.*

[Stenographically Reported by C. C. Mapes, M. D.]

### MONSEL'S SOLUTION IN THE TREATMENT OF DIPHTHERIA.

DR. P. GUNTERMANN: I want to give my testimony to a drug that I have used for the last two years exclusively in the treatment of diphtheria, *i. e.*, the local application of the sub-sulphate of iron (Monsel's solution). Since the report of some physicians from Bowling Green, before the Kentucky State Medical Society, I have treated all cases of diphtheria with this solution, and in no case have I seen any trouble, and they have all gotten well. The statement of the Bowling Green physicians was to the effect that they had treated 250 cases by this method with only one death. I have treated in all about eighteen cases with Monsel's solution, with no deaths thus far. I was called to see the last case three or four days ago; the attack was a very severe one, but after the second application of Monsel's solution the membranes separated and the child has rapidly convalesced. In another family of three children, the oldest, aged about eight years, died of diphtheria, pronounced so by the attending physician, and also by one of our most prominent specialists who was called to do an intubation. Everything seemed to be all right, but the child died. I was called afterwards to treat the surviving children suffering from the same disease, and under the use of Monsel's solution they made rapid recoveries.

I simply wish to give my testimony in favor of Monsel's solution in the treatment of diphtheria, confirming the statement made by others before the State Medical Society. Since the results have been so favorable, I have used nothing else. It should be employed liberally and often. I make a mop like a brush of absorbent cotton, saturate it with, perhaps not less than a dram of the solution, and swab out the throat thoroughly.

#### DISCUSSION.

DR. J. W. IRWIN: I have listened with a great deal of interest to the remarks made by Dr. Guntermann concerning the use of Monsel's solution locally in the treatment of diphtheria. I was trying to think just when I had made use of that drug myself, and I recollect now that it was in the spring of 1874. I was called to see a few cases of diphtheria in the country, about twenty-six in all, in a little village near Evansville, Indiana. Four or five children died in one day. They had been sick for two or three days only, it being a very malignant form of diphtheria. I had just read an article written by somebody in Pennsylvania, who had spoken of the wonderful effect of Monsel's solution in diphtheria and like every new thing it was lauded to the skies. I applied Monsel's solution of full strength. In those days absorbent cotton was not as much in use as now, and I do not think at all, at any rate I used sponges; I saturated them with Monsel's solution and had applications made three or four times or oftener each day. Out of the twenty-six cases which came under my observation at that time, not in a dying condition when I was called, twenty-one of them recovered. I then thought it was an important thing to know that we had such a powerful and effective remedy against diphtheria. In the next cases I saw I was less fortunate with the use of Monsel's solution; there were three children taken ill in one family and all died notwithstanding the prompt use of Monsel's solution. The fourth child was not taken ill at the time the others were, and I thought certainly Monsel's solution applied early in that case would prevent its taking the disease at least in a violent form. A few days later this child, about six years of age, was taken ill and Monsel's solution (Squibb's) was used in full strength, to which solution ten per cent. of pure carbolic acid was added, believing in the germicidal effect of carbolic acid, as it was shortly before that time Sir Joseph Lister had made his well-known experiments with carbolic acid, and the idea of antisepsis was prevalent. Neither Monsel's solution nor carbolic acid had any effect in arresting the disease, notwithstanding the fact that both were faithfully applied when the membrane first appeared as a minute patch. The case went on from bad to worse until the child died, and thus four children in one family died of diphtheria notwithstanding the solution of sub-sulphate of iron was faithfully applied locally, and to which had been added ten per cent. of pure carbolic acid. I then lost faith in the local application of Monsel's solution as a panacea in the treatment of diphtheria. I found, however, that it had a place, not as a panacea or real curative agent, but it had the effect of lessening the deposits in the throat that were not too much attached, and by its local effect the patient was enabled to swallow immediately

after its use. For this reason I consider it an important remedy in the treatment of diphtheria, as it frequently happens where the tonsils and the arch of the soft palate are involved, as I have often seen, that the patient cannot swallow, but after the use of Monsel's solution this may be accomplished.

So that my experience with Monsel's solution in diphtheria without any other application has not been as favorable as the Bowling Green doctors have suggested. It has a place in the treatment of diphtheria; but I would advise that the fellows act very cautiously in using it, inasmuch as it is a very powerful astringent, and in the cases of young children it is often very exhausting to them, causing difficulty in breathing, and the shock after its use, especially when they have to be held while applying it, is often very injurious to their welfare.

---

SOME REMARKS CONCERNING THE WORK OF DR. MARTIN.

DR. C. G. LUCAS: I have concluded this evening to occupy your time for a few minutes in speaking of the work I saw abroad, particularly of Dr. Martin, of Berlin, with whom I spent two months some time since, and of all gynæcologists I have ever seen, either in this country or abroad, I regard him as the best. He has a large four-story hospital located on a rather prominent street of Berlin, and has his own clinic. In this hospital he has an outdoor department as well as indoor, and at two periods in the year, May and September, he accepts private pupils. At the close of the year I was with him. His class numbered about thirty, not only Germans, but Americans, Englishmen, Frenchmen, Russians and I think two Italians. He was able to speak all these languages with sufficient fluency to get along very well. He was raised in England and has very good command of the English language. He has a large lecture-room, which is also used as a general examining room and two operating-rooms on the floor above. In one room he does all of his minor work, the other he uses entirely for his abdominal surgery. When he has abdominal sections on hand, all students are required to take off coat, vest, collar and cuffs and pass through a room in which a carbolic acid spray is playing. The patient is brought into the operating-room which is divided by a chain, and placed on the table, naked. For anæsthesia I never saw him use anything but chloroform. He has a chief assistant, Maekenrodt, who sits down on the left side of the table; then an assistant at each end, one who gives the anæsthetic, and another who takes down the history of the case, age of the patient, condition for which operative procedure is resorted to, etc., and the time it takes to do the operation; then he has two nurses. One, Frau Horn, has been with him a great many years and I think is the best nurse I have ever seen.

Dr. Martin in stature is a very large man. In operating he always sits down, his table being divided into four parts, and so arranged that one portion of it can be dropped to allow the bandage to be applied to the patient after the operation is over. He believes in operating rapidly, because he says the longer the patient remains on the table the greater the shock. He makes a very large incision, and just as soon as the incision is made the abdominal cavity is packed with large flat sponges which absorb all fluid and hold the intestines back. He then removes an ovary for instance, and the trained nurse hands him a needle threaded with sterilized cat-gut with which he transfixes the pedicle, ties off the tube and then removes the other ovary if necessary in the same manner. He never uses irrigation of any kind. When he is through with removal of the appendages, the nurse hands him another needle holder complete; he inserts the first suture and it is tied; she then hands him another which is introduced and tied in the same manner. As fast as each suture is introduced it is tied, and in that way he is enabled to operate with great rapidity. I have seen him do an ordinary ovariotomy in four minutes from the time the patient went on the table until she was taken away with the operation complete. I saw him do seven laparotomies in one hour and forty-five minutes altogether. In doing an hysterectomy he removes the uterus entire, that is in a complete abdominal hysterectomy. Vaginal hysterectomies are done by him every day. In abdominal work, which was probably four or five times per week, by the very fine method of postal service in Berlin he was enabled to notify all students to be present at an operation at an early time any day, if they had not been notified the day before. In doing a vaginal hysterectomy he first makes an incision through the *cul-de-sac*, then packs iodoform gauze in the vagina, ligating the broad ligament as he goes along, removes the uterus entire and closes the wound, using cat-gut altogether. He never had any bad results from the use of cat-gut; never uses a clamp. He is a great believer in colporraphy, in fact I have seen him do as many as eight and ten in one morning. In this operation he always makes a diamond-shaped incision, and uses a knife that was invented by his assistant, Frau Horn. It is something the shape of a card-club made of very thin steel, and by using tissue forceps he could pick the mucous membrane up, and rolls the whole thing out. He then sutures through the center of the diamond from above down, takes up about one-third of the tissue; the

next row of sutures from below upward completes the operation, operating under a stream of bichloride of mercury 1 to 10,000. After these cases are operated upon they are taken into another private room where the dressings are applied. I saw him do at least a hundred of these operations, none of which was followed by suppuration. He preserves complete records of all his cases by means of books especially prepared for the purpose. His results are very good comparatively; I think his percentage of deaths are perhaps a little higher than among other German operators, but this I attributed to the crowding of patients in his room and the condition they were in at the time of the operation.

In his touch course I have seen a great many patients examined in one day. A patient would be brought into the room, the students divided into classes of five, each member of the class has a chance to make a diagnosis of every fifth case and an examination of every case. That diagnosis is then either confirmed or disputed by Dr. Martin himself, and if it is an interesting case the condition present is outlined on the board with crayon, then the other class is entitled to examine it. If necessary the patient is anæsthetized in order to allow a more thorough examination.

At the time I was there Dr. Martin was considered to be the best gynæcologist on the Continent. He does not believe in electricity, but uses the knife altogether. He is very courteous to Americans, at least I found him so.

There are a great many other courses in Berlin, one particularly worthy of mention is under the control of Dr. Olshausen. He has a very large out-patient department; with five examining tables and two tables for treatment. While I was there his classes were divided into threes, each man having a chance to diagnose every third case; then Dr. Winters, Prof. Olshausen's assistant, would do exactly like Dr. Martin, either confirm or dispute the diagnosis. In other departments they inserted pessaries, or washed out the uterus as the cases might demand. On Fridays all these chairs would be occupied by cases under anæsthesia, and some very interesting ones are encountered. Cases of abdominal tumors, double pyosalpinx, etc., etc., and every man has a chance to do some gynæcological operation. I saw Prof. Olshausen operate upon one case of double pyosalpinx in the Trendelenberg position, where the adhesions were so great that he tore into the rectum twice. He has a very large operating-room, the floor and walls of which are covered with tiling. He operates as a rule on an ordinary table. He is not a very rapid operator, but usually does his work very nicely. In vaginal hysterectomy as well as minor gynæcological work, his operating-room is so arranged that every man has a chance to see.

I also saw considerable surgical work in England. In one case where an amputation of the cervix was about to be done, the operator had occasion to introduce the sound to steady the uterus, and immediately after withdrawal of the sound a fœtus popped out. They were quite surprised, but went on and finished the operation, then concluded to introduce the sound again, when another fœtus popped out. I saw some very bungling work among the London surgeons, as well as bad diagnosis. One case was operated upon for ovarian cyst; the patient had ceased menstruating some fifteen months before, and had expected to be delivered in January.—About the middle of December she had some little flow and called in a doctor who said nothing was necessary and left her. She had passed the time she expected to be delivered and about the first of April had another flow which continued for three weeks. Nothing was done for her, and she went along until the first of June, when she had a perfectly normal menstrual period. On the Fourth of July when the ovariotomy was done, they found a perfect extra-uterine gestation, the child being very large. The patient recovered and there was no further trouble.

I remember reading several days ago the report of an operation done for cancer of the stomach which brings to mind a case that I saw Mr. Jessop, of the Cancer Hospital, operate on. The patient was a woman thirty-five years of age. Her stomach had been washed out for several days before the operation with a solution of salicylic acid. After the incision was made the cancerous mass was extirpated; the cut surfaces of the stomach and duodenem were inverted and closed with Lembert sutures. A Senn plate was introduced into the stomach and another into the jejunum, sutures tied and abdominal wound closed. In thirty-six hours the patient was taking milk and beef tea and her recovery was entirely uneventful.

I was quite surprised at the manner in which Lister operated; I saw him operate quite a number of times, and he did not even take the trouble to clean his finger nails, but would immerse his hands in a solution of carbolic acid; yet I never saw any bad results following his operations.

So far as my experience leads me to believe, I think the gynæcology at Berlin is superior to that of any other city abroad; for general surgery I think Vienna beats them all.

DISCUSSION.

DR. W. H. WATHEN: Probably I am more interested in the report of Dr. Lucas than some of the other Fellows, because I am personally acquainted with Dr. Martin, having met

him in this country several years ago. While we may not follow Dr. Martin's methods in all particulars I doubt if he has a superior in gynæcological work. Like all of us he has his hobbies, which at times may be carried too far, and he may have bad results or deaths, where perhaps a different method might have been productive of successful results.

I am a little surprised at the remark by one of our Fellows, that pus tubes so often follow his curetting operations, and I feel sure that if such be true, it is because of a lack of antisepsis before or during the operation, for I do not believe there is danger of pus tubes following a thorough curetting of the uterus, if proper precautions are observed. If infection is not by contact there is practically no danger of sepsis being conveyed to the patient from the room or clothing.

During the last two years I have done a great deal curetting for inflammatory and other conditions of the endometrium, and for malignant disease, without the slightest evidence of any immediate or subsequent bad results, but I observe as rigid aseptic and antiseptic precautions as in a laparotomy. The patient is prepared after the same fashion: A hot vaginal douche is followed by a douche of bichloride solution 1 to 2000. After the patient is on the operating table the vulva and vagina are thoroughly washed with a 1 to 1000 bichloride solution. The speculum is then introduced and the vagina wiped dry with gauze or cotton sterilized in and wrung out of a 1 to 1000 bichloride solution. The neck of the womb is cleansed as far as possible with the bichloride solution; all the instruments and gauze used for tamponing are made aseptic in an Arnold's sterilizer. The neck of the uterus is dilated sufficiently to allow the curette to go in easily. I use the sharp curette; the uterus is pulled down by fixation forceps. Beginning at the fundus I curette the body first taking every particle as I proceed and go around the uterus two or three times, until I am satisfied all diseased tissue has been removed. I then curette the neck thoroughly, because I find in many cases the neck is the part containing the most infection. After curetting, the uterus is irrigated with a 1 to 5000 bichloride solution and the cavity tamponed not tightly, but well, with iodoform gauze; the vagina is also tamponed lightly with iodoform gauze. The gauze in uterus and vagina is removed in two days, and a vaginal douche of a 1 to 4000 bichloride solution given. On the third day the patient is allowed to get out of bed and a few days later she is able to go home. I have never used carbolic acid as an antiseptic, and do not think its use is indicated. Demonstrations made by bacteriologists and pathologists have shown that it is of very little use as a germicide. Bichloride of mercury has been proven to be the best antiseptic we have for practical use, and in these cases it is harmless and the results in my experience have been good.

In cancerous disease I curette frequently for the purpose of removing the necrosed tissue and to bring about a more healthy condition by curing the patient of disagreeable symptoms, such as offensive discharges, hemorrhages, etc. When I do a vaginal hysterectomy I always curette thoroughly three or four days before the operation. All the necrosed tissue is gotten away, and the vagina is tamponed; just before the operation I again curette and irrigate with bichloride solution, and I am sure when I open the peritoneal cavity and remove the uterus that I will not convey septic matter from septic tissue. I use no sponges in these operations; I use sterilized cotton that is kept for fifteen to thirty minutes in 1 to 1000 solution of bichloride, is wrung dry and the blood wiped away with it. I use cotton or gauze in all my plastic operations, such as colporraphy, perineorraphy, etc., and have no pus and get primary union.

DR. S. T. BULLOCK: In the last few years at the University we have almost daily practiced thorough curettage of the uterus for chronic inflammatory troubles, which operations are done before the class at the clinic. In cases where septic trouble has followed parturition, we do not use the sharp curette, but in all other cases this is the instrument employed. We take every possible aseptic and antiseptic precaution, and after curetting, in addition to irrigation with antiseptic solution, we ordinarily swab the uterus with tinct. iodine, then pack with iodoform gauze of course, first as Dr. Wathen has said, dilating the uterus with Hank's dilator. If the sharp curette has been used the patieut is usually sent home in a carriage, if otherwise they frequently, after remaining for some hours, are allowed to ride home in the street car or other mode of conveyance. I have charge of the records and have followed these cases very closely, and we have never yet had any bad results following these operations.

### CASE OF DIPHTHERIA.

DR. P. F. BARBOUR: Two months ago I was called to the Children's Hospital to see a child with the history that for three days previously there had been fever and some discharge from the nose. Upon examination I found a small patch, which I diagnosed diphtheritic membrane, in the pharynx posterior to the child's right tonsil. I inferred that the sanious discharge probably came from a diphtheritic membrane in the nose, and my opinion was confirmed by the subsequent progress of the case. I immediately had the

child isolated and for treatment gave tincture of the chlorid of iron 7½ minims every two hours in glycerine. On the fifth day laryngeal symptoms developed and I had Dr. S. G. Dabney intubate. With the intubation I added this treatment: Bichloride of mercury in 1-60 grain doses every two hours, also whiskey, two drams in two ounces of milk. From that time the child received 7½ minims of the tincture of iron, 1-60 grain of bichloride of mercury every two hours, and two drams of whiskey with two ounces of milk. At the same time his nose was syringed out with peroxide of hydrogen solution, 1:4, in which a little bicarbonate of sodium was dissolved. I used the Oakland Co's peroxide of hydrogen, which is supposed to be the least acid of all the preparations, but upon testing it I found it was distinctly acid, therefore dissolved in it a small quantity of bicarbonate of sodium to neutralize the acidity. The seventh day after introducing the tube we attempted to take it out, and did remove it but the child breathed with such difficulty that the tube had to be introduced again. On the tenth day it was coughed out and with it a large piece of membrane, after which the breathing was perfectly free. While the tube was in the throat the child developed purulent otitis media; there was suppuration from both ears. The fever remained high long after the tube was removed.

Of course the case is not especially out of the ordinary, except that there was so much diphtheritic infection, and yet the child recovered. The interesting point to us was that after the removal of the tube the child continued to have fever; it would run up to 103° or 104° F., and once 105° F. was registered. We could find no cause for this because the ears were discharging very freely, and there was evidently no pent-up pus. An examination of the spleen revealed no enlargement; the fever was evidently not malarial, for the child still maintained this high temperature for two or three weeks even under large doses of quinine. The child was only about two and a half years old, and he took from eight to eleven grains of quinine per day, which would have been sufficient to have controlled malarial fever in a very short time. There was no reason to suspect tuberculosis though the child had a scrofulous diathesis. Another interesting point to me was that we gave him rectal feeding. I used for the enema one egg with fifteen grains of salt rubbed up in it; this was given every four hours, and was retained without any trouble. We tried the enema advised by Ringer, port wine with beef, but the child was not able to retain this more than twice. The alcohol seemed to irritate the rectum so it could retain nothing at all.

We did not examine the membrane for the bacillus of diphtheria. Two weeks after the tube was removed, all the membrane so far as we could see had disappeared. We examined the nasal secretions and found no Klebs-Loeffler bacilli at that time; at the end of the third week we again made an examination simply as a precautionary measure before returning the child to the ward; and found no bacilli of diphtheria in either case.

To the conscientious and careful nursing of the two nurses should be given much of the credit of the successful result.

DISCUSSION.

DR. J. W. IRWIN: The case is interesting from two points of view:—first, the age of the patient, and the severity of the disease; second, the extension of the diphtheritic disorder to the nasal passages and middle ear, followed by recovery. I have never seen a case of diphtheritic trouble with anything like the complications reported to get well. The cause of the secondary fever would be a very interesting point to know, for, as a rule, in diphtheria we do not have much fever after the first few days, the tendency is usually more toward depression. The case was certainly carefully managed, and the treatment proved to be effective. I think it is likely that the diagnosis of the case was correct. A case of that magnitude with no sequelæ such as local or general paralysis is also worthy of note, and it may possibly be in that case that the antiseptic treatment prevented it. Another interesting feature in the case is that the deposit had been examined for the bacillus and none found, as it frequently happens that the bacillus can be found for a much longer period than three weeks. The French Academy of Medicine have recently declared that it takes forty days for the contagion of diphtheria to disappear from a patient, and it recommends isolation for that length of time.

---

HYPERPYREXIA IN A CHILD TWENTY MONTHS OLD.

DR. T. S. BULLOCK: I was called yesterday morning to see a child twenty months old, with the history as given by the father, of the child having had a convulsion shortly before. I found the child having clonic convulsive movements of the right side, and when I touched it was impressed with the extreme heat of the surface, and in taking the axillary temperature was surprised to find that it registered 108°F. I immediately gave the child a cold bath and an enema of bromide and chloral, also gave chloroform to ward off a general convulsive seizure. The convulsions, however, on the right side soon became tonic, the left side soon became involved in a clonic convulsive spasm and the child died last night at eleven o'clock, never regaining consciousness.

The case is interesting to me because of the excessive hyperpyrexia, being the highest I have ever seen.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D., AND SAMUEL M. WILSON, M. D.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES

for May. Dr. George M. Edebohls contributes a paper on

**Diagnostic Palpation of the Vermiform Appendix.**

The author has been practising palpation of the vermiform appendix for somewhat over a year. Practically all of his experience, he states, has been gained upon women, only three cases of appendicitis in the male having, during that time, come under his observation. Palpation is best performed in the following manner: After completion of the ordinary bimanual examination of the pelvic organs, the woman is drawn upward upon the table to the extent of a foot or two, her feet still remaining where they were placed for the vaginal examination. This is done for the purpose of unfolding the flexures of the thigh, and rendering the right inguinal region more accessible to the palpating hand. One hand only, applied externally, is required for the practice of palpation of the vermiform appendix. No assistance can be rendered by a finger in the vagina, and very little assistance, and that only occasionally, by a finger introduced into the rectum. The examiner stands at the patient's right and begins the search for the appendix by applying two, three, or four fingers of his right hand, palmar surface downward, almost flatly upon the abdomen, at or near the umbilicus. The examining fingers are passed over the abdomen, in a straight line from the umbilicus to the anterior superior spine of the right ilium, and the character of the various structures noticed as they come beneath and escape from the fingers passing over them. In doing this the pressure exerted must be deep enough to recognize distinctly, along the whole road traversed by the examining fingers, the resistant surfaces of the posterior abdominal wall and of the pelvic brim. The author asserts that the whole secret of success in the practice of palpation of the vermiform appendix lies in the fact that pressure must be made deep enough to recognize distinctly the posterior abdominal wall, the pelvic brim, and the structures lying between them and the examing finger.

The author states that the organ is recognized as a more or less flattened, ribbon-shaped structure when quite normal, or as a more or less rounded and firm organ, of varying diameter, when its walls have been thickened by past or present inflammation. When it is the seat of inflammatory changes the appendix is always more or less sensitive on pressure; the normal appendix exhibiting no special tendencies on being squeezed. A good guide; in searching for the appendix, is formed by the right common and external iliac arteries, the pulsation of which can be easily and plainly felt. The appendix is generally found almost immediately outside of these vessels. At its base it is separated from the vessels by a space of one-half to one inch, while lower down in its course it generally crosses very obliquely the line of the arteries.

Theoretically, two conditions mainly militate against the successful palpation of the vermiform appendix after the method above described, namely, the variable situation of the appendix and its frequent location behind the cæcum. Practically, the author has found that these difficulties in the way of diagnostic palpation are not so great as one would suppose.

As the result of these observations the author would lay down a broad rule in regard to operating in appendicitis: Not to operate in chronic cases unless the diseased appendix can be felt, nor in acute cases unless by palpation the diseased appendix or the presence of a tumor can be recognized. Anæsthesia may be necessary, in exceptional instances, to decide the question.

Dr. Reynold W. Wilcox discusses

**Uræmic Hemiplegia,**

presenting the following conclusions:

1. Uræmic hemiplegia is a distinct form and should be recognized as such.
2. The peculiarities are its mobility, variability, and complete recovery.
3. The diagnosis rests upon antecedent history, condition of the urine, and temperature curves.
4. The dominating factor in the treatment is the uræmia.

Dr. John K. Mitchell contributes a paper on

**The Effect of Massage on the Number and Hæmoglobin Value of the Red Blood-Cells.**

The author sums up the results thus: In health, massage increases the number of red corpuscles, and to a less degree and not so constantly their hæmoglobin value. In all forms and grades of anæmia there is a very constant large increase in the number of the red corpuscles after massage; this is greatest at an interval of about an hour, after which it slowly decreases. This decrease is postponed more and more if the manipulation be daily repeated. An improvement also takes place in the general tone of the circulatory and muscular systems. There is an occasional but inconstant increase in the hæmaglobin value, and this increase is proportionately less great than that of the cellular elements.

Massage is of great and certain value in high-grade anæmias and is without danger in such cases, no matter how feeble. It is evident that the present definitions of anæmia are insufficient. An essential part of the description in all of them is that there are defects of number, of color, or of both, in the blood. This is not necessarily or always true. The fault may lie in a lack of activity or of availability in the corpuscles. Lastly, neither an anæmic appearance nor a blood count is alone enough for a certain diagnosis. Other

signs must be used as a check on the blood examination for the establishment of the existence of anæmia. The white blood corpuscles have not received sufficient attention in this study, although it seems as if in most cases they were increased as well as the reds.

Even in direct anæmia caused by hemorrhage, massage may be a valuable aid in the treatment both by the impetus it will give to the cells indisposed or disabled for free movement, and by the stimulation of the making of corpuscles. The author has hopes soon to publish some facts as to the application of manipulation to such disorders.

The excess of blood brought into the circulation by massage may be one of the reasons why in occasional sensitive patients we see such discomforts as headache follow its use. Practically we have added a certain number of millions of cells to their tissues, and need not be astonished if some signs of plethora result.

It is evident that massage has complex effects and that the numerical increase of the corpuscles, the added hæmaoglobin value, and the better circulatory and muscular tone, may be due to many causes operating together—a vasomotor nerve stimulation, a direct hastening of the venous currents, an indirect hastening of arterial flow, an improved metabolism, are only some of them.

Dr. George W. Crary presents a paper on

**Myxœdema, Acquired and Congenital, and the Use of the Thyroid Extract.**

The author states that we must bear in mind that in treating congenital myxœdema we have not a pre-existing condition to which we can bring back our patients; but that in these cases the first step in the treatment is to restore the child's health, and the second step is to maintain the child in a normal condition, so that the development of its mind and body will progress as in any other healthy child of the same apparent age. That such development will take place, he feels sure; but until the cases have been kept under observation and treatment for some years, absolute proof cannot be had. It is his belief that if we break away from the term cretinism, with its vivid picture of the "pariah of Nature," and look more closely for the symptoms of myœdema, we will find that many so-called idiots, imbeciles, cases of arrested development, etc., among children, are in fact cases of functional inactivity of the thyroid gland, and hence susceptible of treatment by thyroid extract, with improvement, and perhaps even cure.

He sums up the effects of thyroid administration as follows:

Increased matabolism; shown by—

1. Elevation of temperature.
2. Increased appetite, with more complete absorption of nitrogenous foods.
3. Loss of weight, with nitrogen excreted in excess of that taken in the food.
4. Growth of skeleton in the very young.
5. Marked improvement in body nutrition generally.
6. Increased activity of mucous membranes, skin and kidneys.

The rheumatic symptoms and the anæmia are not only not relieved, but are most frequently aggravated.

Dr. F. Parkes Weber contributes a paper on

**Muscular Cramp, in Relation with the Phenomena of Angina Pectoris and "Intermittent Claudication of the Extremities."**

An explanation of ordinary muscular cramps (such as those sometimes affecting the legs of healthy persons after violent exercise and at night time) is that they are due to the irritation caused by the accumulation of waste products in the affected muscles. By the waste products the endings of the centripetal nerves in the muscles are irritated and the cramp or tetanic contraction is a reflex result. The author gives the chief points of his paper as follows:

"True angina pectoris has long been separated from the nervous cases, or 'pseudo-anginas;' it has been regarded as due to stenosis of the coronary arteries and as analogous to certain premonitory signs of dry gangrene, due to stenosis of arteries in the extremities. In the present paper he does not pretend to have discussed these questions in their entirety, but has confined himself to the role played by muscular cramps in relation to the other phenomena. In this paper it is maintained that muscular cramp does not take any necessary part in angina pectoris or in the phenomena preceding senile gangrene in an extremity, but that cramp is likely to occur in any muscle where an accumulation of waste products takes place, whether this accumulation be caused in healthy muscles by rapid catabolism due to excessive exercise, or by insufficient removal of the waste products in the cases of disease due to stenosis of the main arteries and consequent diminution of the blood stream through the affected part. It is further held that these cramps, when they do occur in angina pectoris, are expressed by the syncope, which may accompany the attack and lead to a fatal termination."

**Compound Tincture of Coal Tar**

is described by Dr. Louis A. Duhring. Summing up the result of his investigations, the author concludes:

1. That the best tincture of coal tar is made with the aid of tincture of quillaia.
2. That the strength of the tincture of quillaia should be 1:4, with 95 per cent. alcohol.
3. That the coal tar (1 part) should be digested with the tincture of quillaia (6 parts) with frequent agitation, for not less than eight days, and preferably for a longer period, and finally filtered.
4. The resultant product is a brown-black, clear tincture, which upon the addition of water forms a cleanly yellowish emulsion, the color and certain other characters varying with the kind of coal tar employed.
5. The tincture is stimulating, and is prescribed usually largely diluted, with from 10 to 60 parts of water, as a wash, and is useful where tar is indicated, as in certain forms of eczema, psoriasis, pruritus, and in other inflammatory diseases of the skin. It is often more useful when employed weak than strong.

This preparation, which may be designated as "compound tincture of coal tar," takes the place of several similarly composed proprietary preparations, known as "liquor carbonis detergens," and "coal-tar saponine."

**The Cultivation of the Tetanus Bacillus**

is described by Langdon Frothingham, M. D. V. To obtain pure cultures of the tetanus bacillus from cases of traumatic tetanus, or experiment animals, the following method is recommended:

1. Inoculate alkaline bouillon with the pus from the wound, or pus being absent, small bits of tissue from the inside of the wound; or in experiment animals inoculated with pure cultures, bits of tissue from the region of the point of inoculation are used.
2. Place tubes in an atmosphere of hydrogen and in the breeding oven for forty-eight hours.
3. Examine microscopically, and if tetanus bacilli are present—
4. Heat from three-quarters of an hour to an hour in water-bath previously heated to 80°C.
6. From heated tubes inoculate fresh bouillon, and place in thermostat under hydrogen for forty-eight hours.
6. Test purity by microscopic examination and cultures in gelatin, agar, etc.
7. Test virulence on mice, white or gray.

The remaining paper in this issue is the report of "Eight Cases of Beri-beri," by Henry C. Boenning, M. D.

---

THE NEW ORLEANS MEDICAL AND SURGICAL JOURNAL

for April. Dr. Adrian Hava writes of

**Spontaneous Combustion of the Human Body.**

His subject refers to instances where persons, usually old, fat, and addicted to alcohol, and always complaining of cold, have been found dead or dying, and partly burned up, usually burning when found. In some cases this has led to trial of others for murder, and such a case is mentioned.

In common with most of those writing about this subject, the author originally believed that the fire was due in some way to the alcohol consumed; but in trying to prove that this might be so, he found that a body soaked for some time in alcohol, and with the veins then injected with alcohol, would not burn. The alcohol, of course, could be set on fire and would burn for some time, but would leave the body intact. Also, animals, poultry, etc., to which a quantity of liquor was given daily for some time would yield alcohol after death only if it had been given for the last time very shortly before death. The reason for this is that the alcohol is absorbed by the tissues only as carbonic acid and water.

The other prominent peculiarity of the victims of this strange accident was complaint of chilly sensation and drowsiness resembling alcoholism: all of them used to sit near a furnace or charcoal brazier, and the author found that the symptoms of poisoning by carbon monoxide, the fumes given off from charcoal, were (in a person habituated to it) prostration, chilly sensations, bronchial irritation, redness of face and skin, irresistible desire to sleep; finally insensibility and death.

Experiments were now made on rabbits and poultry, to prove that they might absorb this gas for some time, and yet live and grow fat. These experiments were satisfactory, and after death it was quite possible to ignite the bodies, and this once done, the charred surface acted as a wick, the fat melted and burned, and the heat became intense. Water sprinkled on the body in this state caused an apparent increase in the combustion, a phenomenon noted in the case of human bodies.

Dr. Allen T. Reed describes a case of

**Abscess of the Spleen.**

The literature on this subject is, the author says, scanty, and the number of reported cases small. Pyæmia, malaria, and traumatism are possible causes.

A married man, thirty years old, had been treated for at least two months for pneumonia, and when seen by the author had a pulse of 120, temperature 103°, accelerated respiration, and clammy skin.

"He had had cold, and sweating spells, loss of appetite, occasional attacks of diarrhœa, dry hacking cough and enlargement in the left hypochondrium."

Previous to being taken sick he had been chopping with an axe for two or three weeks in such a way that the axe handle occasionally struck him in the side.

One evening he was suddenly seized by chill, high fever, cough, hectic flush, and had for several nights before this had pain in the left side. The case was then diagnosed as pneumonia, and after being treated for some weeks for this, was seen by the author who diagnosed splenic abscess, put him on general supporting treatment, to prepare him for an operation which the family postponed on seeing the good effect of systemic treatment. The abscess ruptured and a post mortem confirmed the diagnosis. The author includes in his paper a plea for greater attention being paid to physical diagnosis in medical colleges, and a hope that the laity may become educated to allow post mortems more frequently when they are desired.

Dr. Randolph Winslow read before the Clinical Society of Maryland a

**Report of Two Surgical Cases.**

The first was a successful gastrostomy and was interesting from the fact that the patient was a child three years of age, and that at one time the temperature before operation is reported as low as 90°, and 93° for a longer time.

The other case was a suturing of the intestines for perforation by a gunshot. It was followed by secondary ligation (for aneurism?) of the deep circumflex iliac, and by incision to empty an abscess in the iliac fossa.

In the subsequent discussion one or two members thought that in cases of gunshot of small calibre they would rather wait until the effects of perforation became manifest before doing a laparotomy, hoping that a small perforation, if it occurred, would close spontaneously. Other members thought it much

safer to open at once, and leave nothing to chance.

This number also contains a paper by Drs. Roland G. Curtin and Edward W. Watson on Influenza, which appeared in THE MEDICAL AND SURGICAL REPORTER of April 7th, also a paper from the *St. Louis Medical and Surgical Journal*, in which Dr. Homer M. Thomas advocates galvano-cautery as the most satisfactory treatment for pharyngomycosis, and from the *Pacific Medical Journal* an article by Dr. P. M. White on

**Sponge Grafting.**

In treating chronic ulcers, particularly varicose, and syphilitic ones the author is in the habit of making small incisions in the edges, provided these are indurated, then cutting a thin, accurately-fitting piece from a fine silk sponge, saturating it with any antiseptic solution, and pressing it neatly into the ulcer. This is now kept in place by small adhesive strips, then covered by one layer of cheese-cloth, and over this the usual cotton and roller. The adhesive strips and sponge are left in place; the sponge is moistened daily with any antiseptic except bi-chloride; the superficial dressings are changed daily.

It is only necessary to renew the sponge graft in cases of persistent indolence, and sanious pus. The final result is usually free granulations which adhere to the sponge, cause its absorption, and finally healing—*the author claims without a cicatrix.*

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## MEDICINE.

### Essential Paroxysmal Tachycardia.

Joseph Eichberg (*Cincinnati Lancet-Clinic*), in speaking of this affection, calls attention to the following points:

1. The affection is paroxysmal. The most careful examination fails to discover any cardiac derangement in these cases. Exertion does not cause an attack.

2. The earliest age at which a case has occurred was the ninth year.

3. Sex does not influence the disease in any way.

4. There may be slight rise in temperature during an attack, though it is unusual.

5. Auscultation, during an attack, shows that the heart is regular, though very frequent.

6. The main feature of the heart sounds is the resumption of the fœtal character.

7. The pupils are perfectly normal and active during an attack, showing absence of irritation of the cervical sympathetic.

8. The attacks occur without premonition or excitiug cause, often during sleep.

9. The attack reaches it maximum immediately The cessation is equally sudden.

10. The disease is a serious one, though seldom fatal. It is impossible to foresee a fatal termination in any case.

11. Some persons suffer for many years from these attacks. In severe cases it certainly tends to shorten life.

12. The secondary results of these attacks are very important. There is disturbance of the respiration; and acute dilatation of the heart. This latter disappears with the cessation of the attack.

The most frequent cause is mental and physical overwork. In pathology, is primarily a neurosis. Of medicinal agents, bromides and morphia in small doses, with proper rest, do most good. Digitalis is useless. No time should be wasted in trying the cardiac tonics. A rigid regulation of the mode of life is imperative. Tobacco must be abandoned.

### Convulsions in Young Children.

M. Simon (*Gazette des Hopitaux*), in a clinical lecture on this subject, remarks that the following indications should be followed:

1. Empty the digestive canal. Very many cases of convulsions are due to some condition of indigestion. For this purpose give a large enema and dose of some laxative, as castor oil, epsom salts, etc.

2. Calm the nervous system. For this he recommends a mixture of chloral, musk and water.

3. Active treatment of the skin, as by hot baths, mustard baths, or sinapisms.

4. The treatment of the case after the attack, so as to regulate the health and prevent a recurrence. This is mainly a question of the treatment of the digestive organs. Sometimes the convulsions are due to derangements of the kidneys. This requires treatment directed to these organs, such as hot air baths, proper diet, diuretics, and warm water baths.

### Essentials in a Healthful Home.

The site for a house should receive careful attention of the tenant, purchaser, or of one proposing to build. A good site may mean life and happiness, and a bad one disease, suffering and death.

1. It should be dry. Avoid, as you would death, a damp location. In a town or city carefully ascertain whether or not it is on "made ground." Avoid it. Avoid ground underlaid with clay, for it will always be damp.

2. Elevated on a hillside or gentle knoll, never in a hollow. The hillside is warmer and dryer than the hollow.

3. Not close to a swamp, slow river, milldam or land which is overflowed a portion of the year, nor in such a place that the prevailing winds will bring to the house pestilence from a milldam, etc.

4. In as good a neighborhood as possible, away from foctories, saloons, etc., and near schools and churches.

5. In a village or town build on as large a lot as possible, thus securing air and sunlight. Build back from the street, thus avoiding the dust of the dry season and the curious gaze of every passer. Secure a yard in which trees and plants will furnish both exercise and health.

6. In the country build back from the highway, giving an abundance of room for trees and shrubbery about the house. Do not select a place where your family will be isolated from all social intercourse, so necessary to the health of mind and body.

For the aspect, let the house be so placed that it will receive the most sunlight and fresh air, especially from the summer winds. Avoid, even if offered rent free, a damp, dark house, with no chance of the free air of heaven to sweep through it. If the house is only one room deep, it does well to face it to the south or southwest; but if it is two rooms deep, those on the north side never receive any sunlight, and are apt to be damp. For a double house it is the best to face to the east. Then the morning sun will warm up the front and the afternoon sun the rear of the house, and thus all the rooms will be bathed in light and warmth. The living-rooms should always be warmed by the morning sun. This hint is worth a great deal as a health matter. For when the sun cannot enter, the doctor must enter. If the cold winds from the north and west are severe in the winter, they may be broken by a cluster of evergreen trees planted on those sides. In country places a good aspect should be secured without reference to facing the house square with the street.—*Pacific Health Journal.*

---

### Habitual Nose-Bleed.

Dr. Wm. Rath (*Wien. Med. Presse*) says: To the general causes of nose-bleed belong:

1. Disease of the vascular system and a change in the composition of the blood itself, such as is found in scurvy, purpura, hemorrhage, hemophilia, etc.

2. The fragility of the blood vessels following acute infectious diseases (acute exanthemata, typhoid, diphtheria), also subacute and chronic infectious diseases (malaria, pyemia, septicemia).

3. All those diseases which lead to obstruction of the circulation (valvular disease of the heart, diseases of the lungs, tumors of the mediastinum, cirrhosis of the liver, Bright's disease, amyloid degeneration of the kidneys and liver, and lastly, also the physiological process of pregnancy).

4. Vicarious menstruation, a cause now and then observed.

To the local changes in the nose causing nose-bleed belong:

1. Erosions and superficial ulcerations of the mucous membrane.

2. Varicose dilatation of the veins on the anterior portion of the nasal septum.

3. Perforating nasal ulcer.

4. Ulceration of the mucous membrane and of the bones in the course of syphilis, tuberculosis, lupus, and other destructive processes.

5. New growths—especially sarcoma and soft carcinoma.

6. A certain fragility of the mucous membrane, for which, microscopically, no cause can be assigned.

7. Trauma.—*Medical Brief.*

---

### The Causes and Treatment of Migraine.

Dr. H. Gradle (*Chicago Medical Recorder*) disputes the gouty and neurotic origin of nervous sick headaches. He contends that the most frequent etiological factor in migraine is astigmatism. The degree met with in most cases that are well marked is three dioptrics. High degrees of astigmatism often cause only poor sight. Hypermetropia sometimes gives rise to it. Nasal diseases may also cause migraine. Intestinal catarrh also may be a cause.

The treatment consists in a the correction of these conditions. When properly carried out, the results are usually very good. The only drug that seems to have any permanent influence on this disorder is cannabis indica. This cures about one-third of all the cases. It must be continued for a long time, however. This drug often aborts an attack. When it does not, antipyrine usually does.

---

### A Plea for Chloroform in Labor.

(W. B. Sprague, M. D., of Detroit, in *Amer. Lancet.*) The advantages of chloroform anæsthesia may be enumerated thus:

1. More rapid dilation of the cervix. The cervix and os are supplied with nerves from the cerebro spinal system, and pass readily under the influence of an anæsthetic. Even Barnes says: "Here it is often of signal service." It is especially useful from this standpoint, in cases of rigidity or spasmodic action by which the os gives unusual resistance and the result is lack of harmony of action in the different parts of the uterus.

2. It preserves the perineum by relaxing the muscles, allowing for manipulation, making it possible to deliver the head in the intervals of the pains rather than with an expulsive effort.

3. The mother often restrains the contractions to the uttermost until she is anæsthetized. The abdominal muscles are both voluntary and reflex. Labor can be greatly delayed by this restraint, and it is in these cases that labor proceeds more rapidly with than without the anæsthetic.

4. In cases of heart disease, when palpitation and dyspnea are induced, the chloroform quiets the heart and removes an element of considerable danger.

5. The exhaustion and shock of severe labor are averted, and the contractile energy of the womb is conserved, thus protecting against post-partum hemorrhage.

6. Reflex contractions of the abdominal muscles seem to be more easily induced by artificial stimulation—pressure on the perineum, etc., in the anæsthetic than in the non-anæsthetic state.

7. Most important of all, in my estimation, is the amelioration of suffering to the parturient woman. In my experience it has been rare to find a mother give birth to her child without calling upon her doctor for help and relief. These cries were often agonizing, and the lying-in chamber was to me frequently a chamber of torture before I learned that I could so easily and safely respond to them. I cannot believe that any physician can have the heart to refuse this help after giving the subject careful consideration. Lusk says: "Few practitioners give themselves the trouble to master the necessary *modus operandi* of the use of anæsthetics, to study the limitations of their usefulness, or to learn the conditions of their safe administration. It is to such that I appeal.

---

### The Punishment for the Crime of Producing Abortion.

In England and Ireland the punishment is penal servitude for life, or a less term. Should the mother die, the crime becomes murder, which may be punished by death. In Scotland (says *The Lancet*), the punishment is arbitrary; in France, Spain, the German Empire, Austria, Hungary, Italy, Russia, Norway, Sweden and Denmark — in short, throughout the whole of Europe—the crime is punished by imprisonment for from six months to twenty years, or for life. In Sweden the penalty is death if the mother dies; and in Russia the mother, if a consenting party, may be exiled to Siberia; in the Dominion of Canada the penalty is imprisonment for life; in Nova Scotia, Quebec, Ontario, British Columbia, and in Prince Edward Island it varies from imprisonment for two years to for life; in New Brunswick the penalty is death; in Australia and New Zealand the punishment is very severe, ranging from two years' imprisonment to penal servitude for life; in the United States it is punished with fines ranging from $100 to $5,000, with imprisonment for long periods, and with death.—*Med. Record.*

---

### A New Method of Artificial Respiration in Asphyxia Neonatorum.

Dr. J. Harvie Dew, of New York, has described a new method of artificial respiration in newborn babes, which may be summarized as follows:

Grasp the infant with the left hand, allowing the neck to rest between the thumb and forefinger, the head falling over backwards; the upper portion of the back and scapula resting in the palm of the hand, the other three fingers to be inserted in the left axilla, raising the arm upwards and outwards. Then grasp the knees (or ankles, if baby is small) with the right hand in such a way as to hold them with the right knee resting between the thumb and forefinger, the left between the fore and middle fingers. Next, depress the pelvis and lower extremities so as to allow the abdominal organs to drag the diaphragm downwards, and with the left hand gently bend the dorsal region of the spine backwards. Retain for two or three seconds, then reverse the movement, bring the head, shoulders and chest forward, closing the ribs upon each other, and at the same time bring forward the thighs, pressing them on the abdomen. Retain two or three seconds. Repeat movements.—*Canadian Practitioner.*

---

### Chapped Hands and Face.

Dr. W. P. Spratling says (*Med. Rec.*) a most excellent remedy for chapped hands and face, and one that, if properly used, will cure the most painful cases in from twelve to twenty-four hours, is compounded as follows:

℞

| | |
|---|---|
| Tr. benzoin co. | min. x |
| Alcohol | ʒ ij |
| Aquæ rosæ | min. xxx |
| Glycerini | q. s. ad ʒ j. |

M. Sig.—Apply to chapped surfaces at night, after they have been washed with soap and warm water, and thoroughly dried

A second application is rarely required. This remedy is equally efficacious in the treatment of fissured, bleeding and sore lips.

---

### Pruritus Vulvæ.

Dr. Ohmann Dumesnil recommends the following:

℞

| | |
|---|---|
| Hydrarg. bichlor. | gr. iss |
| Ammon chlor. | gr. ii |
| Ac. carbolici | ʒ j (more or less) |
| Glycerini | ʒ ii |
| Aq. rosæ ad | ʒ viii |

M. Ft. lot. Apply frequently.

—*Canadian Practitioner.*

---

### Treatment of Anthrax in Man.

Sestina (*Lo Sperimentale*) reports a case of anthrax infection which was successfully treated by a method first adopted by Mafucci, namely, by the injection into the affected parts of rather large quantities of phenol solution. On the first day eight injections of 1 g. of a 3 per cent. solution of carbolic acid were made into the parts attacked. On the second day three injections of a 2 per cent. solution, and on the third day two more injections of 3 per cent. solution were made into the freshly œdematous parts. The lesions were covered with sublimate dressings, and phenate of quinine was given internally. Notwithstanding the large amount of quinine taken, there was at no time any sign of carbolic acid poisoning. One more interesting point about the case is the bacteriological investigations which showed that the anthrax bacilli did not get into the general circulation, but remained confined to the parts immediately surrounding the original point of infection.—*British Medical Journal.*

## SURGERY.

### Treatment of Puerperal Mastitis.

Dr. J. W. Russey, of Chattanooga, believes compression of more general utility than any simple measure, both prophylactic and curative. To be efficient for the former purpose, it must be used early after labor. The chest binder of Dr. Guiterras, is a most satisfactory means of applying pressure. If abscess forms, pus should be evacuated early and perfectly. Washing the abscess cavity is preferable to drainage tubes. If drainage is necessary, horse hair is to be preferred to rubber tubing. Great care should be taken in selecting point for incision, if circumstances admit, on account of scar in cosmetic point of view.—*Tri-State Medic. Soc. Trans.*

### The Parasite of Cancer.

On several occasions we have called attention to the investigations of Professor Adamkiewicz, of Vienna, since they promised to throw more light on the obscure etiology of carcinoma. In his latest article, which is published in the *Wiener Mediziniche Presse*, the author formulates the results of these investigations as follows: "The true and characteristic element of cancer is a coccidium. From it originate spores (larvæ), which in turn develop into coccidia and amœbæ. Metastases are produced by migration of the larvæ, coccidia and amœbæ to different parts of the body. The development of larvæ takes place within the epithelial and endothelial cells of the diseased area. The parasite, when developed, lives outside the cell and forms an integral portion of the cancerous tumor. It destroys the epithelia, but never causes them to proliferate, and it seems probable, therefore, that what appear to be epithelial proliferations are frequently colonies of coccidia and amœbæ." Adamkiewicz calls this parasite the coccidium sarcolytus, and considers it identical with the epithelial cell of cancer. Korotneff, who has followed a similar line of investigation, reaches essentially the same results. He goes even further and gives a minute description of the cancer parasite and its mode of development. Viewed with his eyes this formidable animal, when fully formed, is a gregarine, having a bulbous anterior end and terminating posteriorly in a sort of tail. It is rarely, however, that the larvæ develop into gregarines; usually they grow into a coccidium or amoeba.

Whatever practical value be attached to these observations they are, at any rate, strikingly original and deserving of careful consideration. Looked at from another point of view, they illustrate exceedingly well the contradictory character of the evidence afforded by microscopical research in some diseases. As seen by one observer, the tissues of a cancerous neoplasm consist of proliferating epithelial cells, while to another, equally careful, these same cells assume the appearance of a destructive parasite. The nuclei of the cell in the one case become the larvæ of the coccidium in the other. How can these differences be explained? There certainly seems an element of optical delusion involved in the question.—*Internat. Jour. of Surgery.*

### Mode of Controlling the Circulation through the Abdominal Aorta.

As patient lies on his back, the assistant, facing patient's feet, stands on the left side of the table, in a line with patient's umbilicus. He then places his closed right hand upon the patient's abdomen a little to the left of the middle line, the knuckles of index finger just touching upper border of the umbilicus, so that the whole shut hand will embrace about three inches of the distal extremity of the aorta above its bifurcation. Then, standing upon his left foot, his right foot crossing his left and resting upon the toes of the right, —an attitude commonly assumed by public speakers,—he leans upon his right hand, and thereby exercises the necessary amount of pressure. With the index finger of the assistant's left hand the weight necessary for the purpose can easily be estimated by the effect produced upon the flow of blood through the common femoral at the brim of the pelvis. Whenever the flow of blood through the femorals is absolutely arrested the abdominal aorta is sufficiently controlled, and no further weight should be applied.—*Annals of Surgery.*

### Thyroid Extract in Myxœdema.

Dr. F. C. Shattuck, of Boston, has treated four cases by thyroid extract, three of these being undoubtedly cases of true myxœdema, which the author believes can be added to the rapidly-lengthening list of cures by this treatment. The other case did not improve, the diagnosis, however, not being certain. Dr. Shattuck calls attention to the fact that in this, as in other diseases, there are differences of degree, total inactivity or loss of the gland being one thing, partial inactivity or loss another. Anginoid attacks are the most important untoward symptom likely to be encountered. It seems probable that the use of the remedy must be persisted in through life, and that larger doses will be required during the cold than during the hot weather. The initial dose, 1 grain (0.065 gramme), was cautiously increased according to the case.—*Boston Med. and Surg. Jour.*

## PATHOLOGY.

### The Form of Peritonitis.

Dr. Roswell Park, of Buffalo (*Medical Age*), goes very fully into the classification of peritonitis. The first method of classification he discusses is the clinical, and divides the disease as follows:

1. The Idiopathic. This form of peritonitis has been long accepted by standard authors; but the writer does not think that any such form exists. In his opinion there is no such a condition as idiopathic peritonitis. There is some disturbing condition, such as rheumatism, malaria, etc.

2. The Consecutive Form. This is the form where inflammation extends to the peritoneum from some other organ or tissue. This happens more frequently from the hollow than the solid viscera.

3 The Perforative Form. Peritonitis frequently follows the escape of the excretory or secretory material of some of the abdominal organs into the peritoneal cavity. This is usually a very fatal form of peritonitis.

4. The Traumatic Form. This includes all forms due to injury, whether the peritoneum be perforated or not. This form may be due to contusions or penetrating wounds.

5. The Chronic Peritonitis. This form is often due to Bright's disease. It has nothing in common with the acute form. It is most likely due to the constant irritation of some toxic irritant. The peritoneum is usually much thickened and opaque.

6. Tubercular Peritonitis. This form may be primary or secondary. Slow forms are not unlike that just mentioned above, with the addition of the nodular appearance of tubercle.

7. Malignant Peritonitis. Less than one-half are primary, the majority are secondary. Miliary carcinoma may be primary or secondary. Generally the symptoms are mild.

8. So-called Latent Form of Peritonitis. There are fatal cases in which pus or other evidences of diffuse or local peritonitis are found, but in which during life such was not suspected. This form is nearly always characterized by the presence of pus.

9. The So-called Fœtal and Uterine Forms. This form may arise from stenosis of the fœtal intestines, as shown by Virchow. An inflammatory form has also been noticed to occur shortly after birth. This is often consecutive to disease of the umbilicus.

The second method of classifying peritonitis is known as the anatomical. This is very simple:

1. There is the general or diffuse form.

2. The circumscribed form may result from injuries. It generally occurs about the cæcum. A rare form is found in the cavity of the lesser omentum, and is usually due to disease of the pancreas.

The third method of classification is the pathological:

1. The aseptic form, usually local, and characterized by hemorrhages or fibrinous effusions, with adhesive tendency.

2. The infectious forms, as staphylococcus, streptococcus, colon infection, septic purulency, putrid from perforation.

3. Specific forms, such as tubercular, gonorrhœal, actinomycotic. Opinions are yet divided regarding a gonorrhœal infection, though held by some good writers to be the case. The colon bacillus is now known to be the cause of peritonitis. It has been shown that the colon bacillus may escape from its usual habitat, and give rise to intense inflammation and very fatal results. The putrid form occurs most frequently after operation for perforation. The exudation is very infectious and foul smelling.—*Dominion Medical Monthly.*

### Parasitic Theories of the Origin of Carcinoma.

Dr. James P. Warbasse, of Brooklyn (in *Brooklyn Med. Journal*), discusses the parasitic origin of carcinoma. He reviews the works of pathologists who have studied this question. He calls attention to the fact, that observers of high repute, by the same methods of study, have reached contrary conclusions. Many good observers regard the so-called parasites as modified cells. The author, however, has found bacteria in carcinoma. While this is true, he holds that there is no foundation for the opinion that parasites are the cause of carcinoma. No bacterium of constant characters is always found in carcinoma. Thus the first condition of a bacterial theory is wanting. No proof has yet been advanced to show that any germs found in a carcinoma can be isolated and then reproduce the growth in another and suitable soil. There are other reasons against the parasitic theory. Carcinomata are related through the endotheliomata and peritheliomata to sarcomata; and through the adeno-carcinomata, to benign adenomata.

Then again, on etiological grounds, we have chemical and mechanical irritants as evident causes of all tumors. So, too, sarcoma or carcinoma may develop in scar tissue. From chronic inflammation of mucous membrane may come polypi, ademonata, or carcinomata. If we contend for a parasitic origin for carcinoma, we must seek for a similar origin to other malignant and benign growths.

The most plausible parasitic theory is that of the sporozoa. But this does not meet the case. The advocates of this theory are met by equally capable observers who contend that what has been called sporozoa are only endogenous cell constituents. Thus the theory of Adamkiewicz is unnatural and illogical, while the theories of Cohnheim, Virchow, Thiersch and Klebs, based on a cellular theory, meet the phenomena best.

### On Meat Diet for Gout.

From time immemorial excessive meat eating has been considered the chief cause of gout. As medical experience corroborates this view, until quite recently gouty subjects were advised to reduce their consumption of meat to the smallest possible quantity; but a few years ago Dr. Emil Pfeiffer advocated the contrary system, and based his conclusions on the quantity of uric acid observed in the case of five healthy and six gouty persons subjected to the particular diet prescribed by him. According to Pfeiffer, this diet consisted chiefly of albuminous substances, such as meat and eggs, and also of fat and green vegetables, while carbohydrates, more especially starch and sugar, were scrupulously avoided; and analysis proved that the secretion of urea and uric acid was increased and the fluids of the body rendered as alkaline as possible. Pfeiffer concluded from the results of the analyses in these eleven cases that healthy individuals excrete more uric acid than gouty patients; but all his subsequent investigations, as well as about two hundred

determinations of the uric acid excreted by one of Mordhorst's patients, gave a contrary result. (The uric acid was determined according to Heintz's method.) As a matter of fact, sufferers from gout extrete, on an average, more uric acid than healthy persons, and a strictly meat diet, so far from rendering the fluids circulating in the body more alkaline, has the opposite effect. It is a well-known fact that the power possessed by a fluid for dissolving uric acid depends upon its alkalinity. Unfortunately, although we can readily render the urine alkaline, it is extremely difficult to render those tissues which are predisposed to the deposition of uric acid deposits neutral, much less alkaline. The urine of a puppy receiving a daily ration of a couple of rolls and about eight ounces of milk is invariably slightly alkaline, whereas that of a similar puppy, only receiving meat as well as milk, never gives anything but a strong acid reaction.—*Provincial Med Jour.*

**The Relation of Syphilis to General Paresis.**

Dr. Frederick Peterson states that his study of this subject leads him to submit the following brief conclusions:

1. A history of syphilis is found in sixty or seventy per cent. of cases of general paralysis of the insane.

2. The fact must not be lost sight of that in thirty to forty per cent. of these cases no history of syphilis, congenital or acquired, is to be found.

3. Antecedent syphilis is seven to ten times more frequent in general paralysis than in other forms of insanity.

4. Syphilis is therefore to be looked upon as a frequent but not a constant factor in its production.

5. But paralytic dementia is not a form of specific disease, not a late syphilitic manifestation, nor is it a form of degeneration dedepending upon syphilitic poison for its origin.

6. The relation of syphilis to general paresis lies in the facts that it is a widespread disorder in all communities; that it weakens the constitution and vitiates the blood in many whom it infects, and that the system is thus prepared in many cases for the direct operation of the final etiological factors of general paresis, viz.: alcoholism, excessive venery, heredity, and mental overstrain and excitement.—*Toledo Med. Compend.*

---

**The Local Lesion of Scarlet Fever.**

Dr. W. Dowson, in a paper on this subject, submits the following propositions, viz.: That (1) tonsillitis is invariably present from the very first in scarlet fever; (2) it is the first sign apparent, both to the patient and the observer; (3) it recurs in relapses; (4) its severity is directly proportional to the severity of the other associated features of the disease; (5) this difference in severity of the throat affection and its relation to the other marks of the disease are recognized as affording a basis, to a great extent, for the clinical classification of the cases of this disease; (6) it is absent just in those cases where there is probability that the local infection takes place at an unusual situation, as in surgical and puerperal scarlet fever; (7) it leaves in the tonsil a permanent lesion, which can be observed long afterward; (8) people who have normal tonsils have not suffered from scarlet fever; (9) people who have gone through an attack of scarlet fever have not normal tonsils; (10) the immaturity of the tonsils at birth, their development in early childhood, the onset and establishment of puberty acting by way of the tonsils, and the atrophied condition of these organs after the age of 30, control, to an important extent, the incidence of this disease. He claims, in fine, that, as in diphtheria, the throat condition and cervical bubo of scarlet fever are the analogues of the chancre and inguinal bubo of syphilis, or of the intestinal ulcers and enlarged mesenteric glands of enteric fever.—*Medical Chronicle.*

---

**Congenital Absence of Lung.**

Professor Tikhomiroff, of Kiev, exhibited a preparation of the right lung and the heart of a woman 24 years of age. There was a congenital absence of the left lung. The case was of interest from the practical as well as theoretical point of view. (*a*) The normal nutrition and development of the body had not been impaired. (*b*) The pulmonary apparatus is, in the first periods of embryonic life, single; for in the case described there was no indication of the left bronchus, and the pulmonary artery had but a single trunk.—Russian correspondence of *La Medecine Moderne.*

## ARMY AND NAVY.

CHANGES IN THE U. S. ARMY FROM APRIL 21, 1894, to APRIL 28, 1894.

Major Charles K. Winne, on being relieved by Major Gibson, is ordered to duty at Fort McHenry, Maryland, relieving Captain CharlesB. Ewing, Assistant Surgeon.

Captain Ewing, on being relieved by Major Winne, will report for duty at Jefferson Barracks, Missouri.

Major Valery Havard, Surgeon, is relieved from duty at Fort D. A. Russell, Wyoming, and ordered to David's Island, N. Y., for duty at that depot; relieving Major Joseph R. Gibson, Surgeon.

Major Gibson, on being relieved by Major Havard, is ordered to Fort Snelling, Minn., for duty at that station, relieving Major Chas. K. Winne, Surgeon.

Captain William L. Kneedler, Assistant Surgeon, will, in addition to his present duties as Post Surgeon, Fort Mason, Cal., perform that of Attending Surgeon, San Francisco, California, until further orders.

Leave of absence for one month, to take effect on or about April 24, 1894, is granted Captain James D. Glennan, Assistant Surgeon.

## THE MARRIAGE OF SYPHILITICS.

WILLIAM G. PORTER, M. D.,* Philadelphia.

Mr. President and Fellows of the College of Physicians: Perhaps no more important or interesting question could have been submitted for our discussion to-night than that of the Marriage of Syphilitics, and I must confess that I approach its consideration with an amount of diffidence which I would not have supposed to be possible some years ago. It would be very easy to dispose of the whole question by giving to our patients who have been afflicted with syphilis and who are contemplating matrimony the celebrated advice of Mr. Punch to those about to be married, "*Don't!*"

But in regard to this question we have a solemn duty to perform; on our decision may depend the future happiness and health, not only of our patient, but that of an innocent and virtuous woman and of children yet unborn.

The subject is so large in all its bearings that it will be simply impossible for me to more than outline some of its more salient points to-night. In approaching the subject we must consider first *our patient.*

If we forbid him to marry, and he takes our advice, we condemn him to perpetual celibacy—we rob him of all the joys of matrimony, of possible paternity.

If we are right in our judgment we have nothing with which to reproach ourselves.

But if we have acted inadvisedly; if he is really incapable of transmitting the disease to others; if he is capable of procreating healthy children; if he has a long life of health and usefulness before him; if, in other words he is cured—we have done him a lasting injury, we have blighted his life, we have robbed the State of a citizen who would in all probability have been more useful married than single.

On the other hand, if we advise our patient, who is or has been syphilitic, that he can safely marry, and he follows our advice and infects his wife or procreates syphilitic children, we have not only injured him, but inflicted irreparable injury on an innocent wife and helpless children.

Now, gentlemen, are there any rules which may guide us in the determination of this most important question? Of course, in an assemblage of physicians like this it would be entirely out of place for me to address you as I would a class of students. You are all more or less familiar with the disease. Many of you are experts in its detection and treatment, both as specialists and as general practitioners. In the limited time at our disposal it would be impossible to offer the proofs of all the statements I shall make; I must, therefore, endeavor to limit myself to propositions which, I think, we can all endorse, and see if we can reasonably make any deductions from them.

In the first place, then, I would say that syphilis may be classified for our purpose into three varieties, viz., the benignant, the moderate, the malignant.

I suppose that it has occurred to all of us *occasionally* to have seen cases of primary syphilis which have been followed by an exceedingly moderate amount of secondary symptoms, and then, almost without treatment, by perfect recovery and the

*Senior Surgeon to the Philadelphia Hospital; Surgeon to the Presbyterian Hospital.

absence of further manifestations; to these I would apply the name of benignant.

By moderate syphilis I mean those ordinary cases in which the disease runs through its various stages without severe symptoms—perfectly responsive to treatment, generally controlled by it, but which it may take many months or perhaps some years to cure.

By malignant syphilis I mean those cases which are very severe from the start, in which the earliest secondary symptom may be a rupia with a profound cachexia, or immediately on the disappearance of the chancre, or even sometimes before it has disappeared, the nervous system of the patient may be profoundly affected.

Recognizing these three varieties, my next proposition is that all three forms are generally curable: the first exhausting itself, the latter two requiring the treatment of the *skillful* physician to overcome them. Gentlemen, I say *skillful* physician, for there is no disease which responds more rapidly to proper treatment or shows worse results when improperly treated than syphilis.

We know that syphilis is curable from the fact that many patients remain indefinitely without a recurrence of symptoms, and more than all that, they not infrequently contract it a second time. But up to the present time no means has been discovered by which we can say absolutely to any individual patient, "You are cured; you will never have a return of this disease unless you contract it again." Because of this many writers on syphilis claim that as we can never say absolutely that a patient is cured, we have no moral right to advise him to take the chances of matrimony; that we can never tell, even after the lapse of years, when a relapse may occur, and the patient, who has supposed himself to be cured, may transmit to his posterity this terrible disease. Now, it seems to me if there is one thing established in medicine, it is the power of medical treatment over the manifestations of syphilis. Who among you has not seen symptoms disappear under treatment almost as if by magic, cases apparently the most hopeless restored to health, and yet it happens to all of us occasionally to see cases which, in spite of systematic and long-continued treatment, persistently relapse. They are not really ill; they go about attending to business and the affairs of life as usual; and yet we know and they know that they are not well; the slightest indiscretion is sure to produce a temporary relapse, and so it goes on for years and years. I think that all of us who have been in practice for twenty-five years or more must recognize the fact that we do not see nearly as many severe cases of syphilis as we formerly did, and yet if we consider the numberless pathological conditions which it most assuredly causes, we must admit that it is still a most serious affection, and one which results much more frequently in death than is generally supposed.

Now, under what, if any, circumstances, are we justified in informing a patient who has suffered from this disease that it will be safe for him to marry?

In the first place, marriage should be absolutely forbidden to any patient who presents at the time he consults us any of the symptoms of syphilis—primary, secondary, or tertiary. Let me quote here from the master of this subject—Fournier:

"What then is marriage in its completeness, gentlemen? Marriage is not only an affair of sentiment, of passion, of convenience, and of interest; to consider it from a standpoint more practical and at the same time more elevated. Marriage is an association freely entered into, where each contracting party is pledged to bring in good faith a share of health and physical vigor, with the view of co-operating, on the one hand, for the material prosperity of the family, and, on the other hand, for the raising of children, the supreme and sacred end of every union.

"Now what, in this case, I ask you, will be the share contributed to the partnership by a husband syphilitic, and not cured of his syphilis? His share will be that of a health compromised, hypothecated, burdened with a debt hereafter due the pox, that pitiless creditor."

"On account of the pox it may happen that this man may experience one day or another such and such serious affections which will ruin his health, such and such an infirmity which will render him incapable of work, incapable of earning his daily bread; and then what will become of the family, of which this man is the recognized support? what will become of his wife? what will become of his children?

"On account of the pox also this man may die. What may happen, he being

dead, to his wife and to these children?

"Is it admissible, then, that a man should think of creating for himself a family when he is liable to fail this family? Is it admissible? Is it right? Is it mortal that a man should dream of having a wife and children when he offers the possible prospect of widowhood to this wife, of orphanage to these children, of poverty to this family? No, a hundred times No!

"Also, and I do not hesitate to say it, the man who is syphilitic, and not cured of his syphilis, fears not nevertheless to append his signature to the marriage contract, commits at this moment a base act, an act immoral and corrupt, an act which good people will be unanimous in condemning."

In the second place, marriage should be absolutely forbidden to all syphilitic patients who have not been subjected to a most thorough, complete, and prolonged treatment.

And finally, in the third place, before sanctioning the marriage of a syphilitic, the requirement of a sufficient treatment having been fulfilled, the physician should be satisfied that he is in perfect health, and that he has had no symptoms, even suspicions, of syphilis for a period of at least two years.

Under these circumstances, and with these limitations, I have no hesitation in telling patients that I think they are reasonably safe in marrying, and I have never yet had reason to regret the advice which I have given.

## HYDROPHOBIA.

HIRAM CORSON, M. D., Plymouth Meeting, Pa.

[Continued from Page 672.]

### CASES.

Case reported by Dr. John W. Green, of New York.—When Dr. Green had heard his statement and that he had been bitten by a dog, he sent for his family physician. They met late at night and advised a course of treatment; but he would do nothing, and said, "There is no hope for me. I must die." The nervous disturbance increased; he could not sleep; was restless; asked them to stop him, so that he could not hurt anyone. At eleven o'clock next day he was attacked with a convulsion; four or five strong men seized him, threw him on the bed, face down, and from fear of injury kept him there till the spasmodic action ceased. When they loosed their hold he was dead.

Yet this case of mental terror was reported to the Committee of the American Medical Association as a case of hydrophobia.

Case 24 of the Report.—Mr. Hopkins was punishing his own dog that showed no signs of ill health or madness, and was bitten by him. Two days later he untied the dog and he went away. This frightened Mr. Hopkins and he began to read about hydrophobia and talk about it. His mind continued to be greatly occupied, but he was not attacked for nearly three months. He was then ordered Dover's Powders, 10 grains every hour; at 10 P. M. tincture of aconite was added. He died sixty-one hours from the attack.

How evident, that it was the result of brooding so long over the fear of hydrophobia.

Dr. Winthrop Sargent's Case.—I have had one case, in 1849, at Manayunk. Drs. Thomas Betten, Conroy and two others saw it. Dr. Betten said he had some experience with the disease and pronounced it a perfectly sure case. The patient had been bitten some weeks prior by a slut that had a litter of pups, with which he was meddling, which aroused her anger and caused her to bite him. After the biting she was chased away with intent to kill her, but they did not succeed, and it was not until some time after the patient died that the slut returned perfectly well and was permitted to live.

How convincing is this case that mental terror led to feelings and acts which this man had heard were attendant on hydrophobia, and the nervous system gave way to his fears.

Dr. W. L. Atlee's Case, No. 11.—Mrs. Kelly, bitten November 3d, 1838. Dr. Penypacker saw her on the 5th. Ordered wound washed with salt and water, and a salt poultice applied. Was advised to try Stoy's cure. Went through a full course after which she was quite well, until about three weeks before Dr. Atlee was called (February 9th, 1839), from which time, until then, she had not been very well. It was a pain in the arm extending to the shoulder, for the last three days. She had blistered the arm after first using a liniment on it. But she had not got relief. Dr. Atlee had been sent for.

It was evident to Dr. Atlee that both herself and her husband feared the dog bite was the cause. Indeed, the husband so declared for himself. It was then 9:30 A. M. From this time the doctor's conduct must have been to her strong confirmation of her worst fears. She had sent for him because of rheumatism, as she averred, and he writes: "I found the symptoms as above described, with the pain more acute in the joints than elsewhere, taking in the character of the local symptoms of acute rheumatism. Her countenance was anxious and her manner a little hurried." I ought to say, that on this visit he did not know that the dog had bitten her. She only complained of rheumatism, and that he prescribed for. On leaving her he told her, "To send word for him in the morning, if she was not better, or sooner, if she became worse." The next morning he saw her at 9:30 o'clock. She had spent a bad night. Soon after going to bed felt as if suffocating, with pain at precordia, etc., and after that could not sleep. Every few minutes she would start up in great distress and sense of smothering. [This increase of distress was evidently due to the doctor's expressed wish to be sent for if she got worse.] It was at this visit, Saturday morning, that Dr. Atlee learned all about the dog bite and the Stoy remedy, so Dr. Atlee adds: "After giving me this history of herself, she said 'she did not believe the disease was from the dog bite,' but her manner disclosed that she secretly believed *that* to be the cause." Dr. Atlee had gone then at 9:30 A. M. and the long story of her case had been told him by her, her husband, too, being present. So it was doubtless 10 o'clock before he left. At one o'clock he visited her again. He writes: "She received me tranquilly and expressed herself glad to see me. Her husband said 'he believed her illness came from the bite of the dog.' She said, 'No; it's rheumatism. I will soon be well of the spasms.'" At 3:30 P. M. he visited her, having his brother, Dr. John, with him. "The visit of my brother produced no unusual agitation. She seemed glad to see us and got up and offered us chairs requesting us to be seated. Called again at 8 P. M.; she was no better. On next day, the 11th, visits at 8 and 11 A. M. and at 3, 6 and 8 P. M., five visits in a day. During that day she was much engaged in prayer. Had Dr. Atlee to read parts of scripture to her, first the 52d chapter of Isaiah. Then she said, 'I am afraid of tiring you, but I would like to hear more.' Then I read eight or nine succeeding chapters, at the end of each chapter asking her if I should read more. She replied, 'You are too kind; but if you are not tired I should like you to read of the sufferings and death of our Saviour.' I then turned to Matthew and read for her. During all this time she remained perfectly tranquil and composed, although her spasms had been so violent before." Before I left she desired to know my opinion of her case. By suggestion of Dr. Atlee a clergyman was called; she talked freely with him. At this time there were four doctors. "The clergyman was engaged with her, in conversation and prayer, about half an hour. During the whole of this period she was remarkably calm and free from spasms, although her paroxysms before and immediately after were frequent and of the most violent character."—p. 277. "It would appear from this," says Dr. Atlee, "as if the exercise of the mind had some mysterious connection with the production of spasms. For as the paroxysms were entirely suspended while the mind was engaged in this all-absorbing question, and as they reoccurred as soon as the mind was not thus exercised, it would indicate almost as close a relation as cause and effect."

[The members of the profession will observe the correspondence between this circumstance of this case, and a distinguishing feature of chorea, viz: the act of volition being necessary to the convulsive movement. For *volition* substitute nervous system.—H. C.]

The case went on. Spasms, no food, no drink, much medicine, quiet rational spells. At no time was it needful to tie her or restrain her. No disposition to bite, no barking like a dog, though she was somewhat hoarse. She sat in a chair during the whole course of this disease fearing suffocation if she should lie on the bed. She died at 11.30 A. M. on the 13th. Four days after the attack began, about as it appears from the history of numerous cases, as life can be maintained (I suppose) under such a fierce strain of the nervous system. Spasms, no food, no water, no rest in bed and much medicine.

### *Effect of a Dog's Bite.*

AFTER SUFFERING INTENSELY FOR DAYS, A MAN DIES IN TERRIBLE AGONY.

Lynn, Mass., June 8.—John Anderson, a Swede, three weeks ago was bitten on the hip by a dog. The wound was not cauterized and Anderson was taken ill on Monday, and at once had a decided antipathy to water.

Tuesday night he began frothing at the mouth and was unable to take food. The sight of strangers caused him great fright. About midnight he began barking and snarling like a dog and raved in delirium. In his struggles he bit at his friends and tore the bed clothing to ribbons with his teeth. He gnawed the footboard and posts of the bed, his teeth sinking into the hard wood. He died in the greatest agony. Consulting physicians pronounced death due to the effect of fright and its subsequent action on the heart.

### *Death from a Dog Bite.*

A YOUTH FALLS A VICTIM TO HYDROPHOBIA OR MENTAL FEAR.

Four or five weeks ago Charles Hensey, a fourteen year old boy, who lived with his parents at No. 39 North 37th street, was bitten by a Dalmatian coach dog he was romping with. The dog had been taught a number of tricks, one of which was to jump from the ground and catch objects from the hand. The boy was engaged in this sport, when one of the dog's teeth accidently pierced a finger of his left hand. The wound was cauterized by a physician, and, as it healed rapidly, the bite was forgotten until Monday last, when the lad began to complain of severe shooting pains in his left arm and shoulder. The boy was employed by Mr. Taggert, a sewing machine agent at 3733 Market street, who, when young Hensey complained of the pains, sent him to Dr. Hopper for treatment. The relatives of the lad, however, objected to Dr. Hopper and sent him to an herb doctor at Bridgeport. This individual laid his hands on the boy and, giving him a cup of tea, said the prespiration that would ensue would drive the poison from the system. No prespiration followed the dose and the lad's relatives, being convinced that there was no poison in his system paid no further attention to his complaints until Wednesday, when he fell in violent convulsions. During the spasms which followed in rapid succession the sufferer foamed at the mouth and displayed all the usual symptoms of rabies. The convulsions were so violent on Wednesday that it required the united exertions of six men to keep him in bed. Towards evening he became quieter and at seven o'clock died. The boy is said to have been excessively nervous and sensitive and the attending physicians are of the opinion that he brought on the convulsions by brooding on the subject of hydrophobia.

### *Died of Hydrophobia.*

Frederick Miller, thirty-four years of age and married, residing in the rear of 903 South 5th street, died at eleven o'clock Saturday night, at the Second District police station, of the most violent symptoms of hydrophobia. Strangely enough he was bitten four months ago by a small dog owned by Robert Clark, a lumber dealer, at Fifth street and Washington avenue. The dog had bitten several persons and its owner had consented to its slaughter. Miller, who volunteered to be its executioner, picked the cur up in his arms, but it squirmed and bit him severely on the lip. The dog was at once dispatched. Miller worried constantly and talked of nothing but hydrophobia, until he showed signs of being out of his mind. He became so violent on Saturday last that he had to be locked up in a station house cell for security.

### *Hydrophobia Again.*

A YOUNG MAN'S WRETCHED DEATH.

Coroner Janney this morning held an inquest in the case of Frederick Miller, 18 years of age, who residedin the rear of No.

3517 Warren street. About three months ago the deceased was bitten by a small dog, which he had killed three days afterwards. Notwithstanding that he had the wound cauterized he was in constant fear of being effected by hydrophobia. About a week ago symptoms appeared which, although not strictly hydrophobia, were alarming enough to call a physician. Deceased complained of dryness in the throat, and evinced a repugnance for liquids. On Friday the deceased was affected with convulsions and on Saturday he underwent the horrible contortions. Once or twice he nearly succeeded in biting his mother, who was trying to calm him. In the latter part of Saturday afternoon his mother was compelled to have him taken to the Second District station house, where he died on Sunday morning. The attending physician testified that the deceased's death resulted more from fear of being affected with hydrophobia than from the actual presence of the disease, and that his death was caused by exhaustion; the result of acute mania, and the jury gave a verdict accordingly.

---

### *Died of Hydrophobia.*

A CASE IN WHICH THE ACTUAL DISEASE WAS STUDIED TO ITS FATAL END.

Jersey City, N. J., December 5. One of the most interesting cases in the pathology of hydrophobia occurred here Saturday, and resulted in the death of Edward Coleman, of 269 Monmouth street this city, yesterday. The boy, a bright lad of six years, was bitten by a terrier belonging to a neighbor on October 22nd last. The dog bit Edward about the head and face in the most horrible manner. The boy was rescued and carried to a physician. Ten stitches were required for the wound in the face.

As it was not believed the dog was mad, the wounds were not cauterized. The reason for this was the terrier had suffered amputation of his tail, and it was thought the pain from the operation had made him vicious, so that when the boy called to him the animal was excited. The dog, it was afterward found, had bitten a cat and two chickens, all of them dying since from the effects. The dog was at once killed to prevent any further possible trouble.

The case was watched with close interest. When the boy a few days ago began to show signs of nervous affection, his parents at once concluded to take him to the Pasteur Institute in New York city. When Edward was presented to Dr. Gibier, in charge of the Institute, an experiment was made by offering the boy some water to drink. A light spasm of the throat was apparent and on repeating the experiment the patient showed plainly the signs of hydrophobia. Dr. Gibier at once decided that there was no doubt of the case, and also that the virus had become so firmly seated in the system that inoculation would be of no avail. He advised, it is said, only a simple treatment to quiet the patient and fortify him as much as possible against the poison. The diagnosis proved correct, and the boy died at his home yesterday with all the symptoms of hydrophobia.

One of the interesting points of the case is that Edward had never heard of hydrophobia, and could not have apprehended the dreadful results. His imagination was therefore not affected and the case is purely an instance of the active force of the rabies virus.

---

### *Hydrophobia Victims.*

A WELL DEVELOPED CASE—THE PATIENT BEGS TO BE KILLED.

Saginaw, Michigan, July 31. Morey Godfreg was attacked by a strange dog, July 4th. It knocked him down and bit him in several places. A few days ago he complained of feeling unwell and remained home from work. Yesterday he went into a spasm at the sight of water and has since that time gone from one convulsion to another; his frenzied exertions to get away from his attendants at times required the united strength of three or four men to hold him. He barks and snarls like a dog and tries to grab his attendants with his teeth, and between the spasms begs his attendants to kill him. The doctors say it is a well developed case of hydrophobia.

---

### *A Boy Dies of Hydrophobia.*

Wichita, Kan., July 31.—Robert Tankersky, aged 12, died yesterday of hydrophobia. Those who witnessed his death described it as horrible. For several hours the boy was in convulsions, and it was as much as four men could do to hold him in

bed. He was bitten months ago, but the wounds soon healed. Three days ago hydrophobia symptoms began to develop. Fear of water was the first noticed. Wednesday morning the boy had his first convulsions, but they were not bad and did not last long. Yesterday morning he was again attacked, and for hours he howled, snarled, and barked, apparently in awful agony, until death relieved him.

*Afraid of Dogs in Heaven.*

A HYDROPHOBIA VICTIM'S ANXIOUS QUESTIONS BEFORE HIS DEATH.

Jersey City, Dec. 6.—Mrs. Catherine Coleman, whose six year old son Edward died of hydrophobia yesterday, says the boy was conscious until the last hour before he died. He asked his mother if there were any dogs in Heaven. If so, he did not want to go there; he did not like dogs. His mother said the boy did not suffer very much. He was always thirsty and hungry during his last illness. He was afflicted with severe convulsions of the throat, which made it very difficult for him to take food.

*Has the Hydrophobia.*

HARRY BRASSINGTON GIVES HIMSELF UP TO THE POLICE.

New York, June 25.—A man who said his name was Harry Brassington walked into the police headquarters at Mt. Vernon on Tuesday afternoon last, and asked the captain in charge to tie him up "for God's sake," as he was suffering from hydrophobia, caused by a dog bite he had received several years ago. The sergeant thought at first he was fooling, until suddenly he became a raving maniac. He flew at policeman Myers and would have bitten him had the other four officers who were present not interfered.

Doctor Banning was summoned and morphine injections were given him, but without any effect. He became rational again in about an hour. An ambulance was summoned and he was conveyed to the hospital. He was taken again with a paroxysm when he arrived there. When it had passed he explained to the doctors that he had suffered from the same cause before and was perfectly conscious of the danger to those who attended to him.

He said that he had been treated by the Pasteur method in this city, and had thought himself cured until on his way home that afternoon he had felt the return of hydrophobia symptoms. At a late hour last night his death was momentarily expected. Brassington is the same man who, a few months ago, was found at Harlem Bridge, suffering from hydrophobia. He was taken to the Harlem Hospital and after being treated a few days was discharged.

## URETHRITIS—SIMPLE AND SPECIFIC.

I. N. BLOOM, M. D., LOUISVILLE, KY.

I have recently had two or three cases which have furnished considerable food for reflection. They were all cases of urethritis. It is now a generally accepted fact among those who are supposed to know, that urethritis is divided into three classes:

1. Traumatic urethritis.
2. Urethritis simplex.
3. Urethritis specific.

A man having gonorrhœa is subjected to specific urethritis which is brought about by the specific germ—the gonococcus of Neisser,—carried from one subject to another, and by its development produces the disease. While there have been some differences of opinion in regard to the causation of gonorrhœa, the above is the most generally accepted theory. I am not prepared to dispute this, but two cases I wish to report have at least been food for reflection for me for some time, and I propose to give the cases first then draw my deductions therefrom, or leave the members of the Society to draw theirs.

The first case came under my observation about a year and a half ago. A man who had been married about ten years contracted gonorrhœa,—at least gonorrhœa was the diagnosis given by his physician.

The following are the particulars: The man had been on a spree and had indulged in one sexual intercourse away from his wife. Two or three days after this, having no symptoms of any kind, he had connection with his wife. About a day following this coitus, he noticed a slight discharge from his penis, and consulted me. The flow when I saw it was mucoid, scarcely muco-purulent in character, about the color and consistency of glycerine. Urination on the part of the patient was painless and there was little or no inflammation around the meatus. At the end of four or five days of ordinary treatment there was no discharge at all from the penis or in the urine; in the meantime, however, for one or two days the flow became more purulent in character, but principally mucoid and remained that way until probably the end of five days when it ceased altogether. He had not practiced coitus with his wife from the time he first consulted me, and she subsequently developed undoubted gonorrhœa which lasted four or five weeks, severe in character, with urethritis, vaginitis and pelvic peritonitis characterized by the usual symptoms and usual amount of severe pain. Previous to the time this man first consulted me, he had had no signs of gonorrhœa for ten years.

The other case—rather there are two of them which are practically alike, one of which I followed very closely, having had a microscopical examination of the discharge made by Dr. Vissman—occurred in a young man twenty-six years of age who came to me about a year and a half ago for a syphilitic affection which was then about two years old. About the same time he told me of a gonorrhœal discharge he had which came on at intervals; sometimes for a week or two it would remain quiet, then become varied in form from a thin gleety mucous discharge to (at times) a decidedly purulent flow. In the course of treatment for syphilis, I saw the patient quite frequently and he paid little or no attention to this discharge, in fact the urethral discharge was only mentioned occasionally and received no direct or thorough treatment The patient seemed disinclined to it, would not use injections nor internal medicines faithfully, and would not limit his desires or the gratification of them.

In June the man fell in love and began to think seriously of marriage. In the meantime three years had elapsed since the development of syphilitic manifestations, to which he had attended fairly faithfully, as a man can do by getting a month's supply of medicine and taking it regularly. His gonorrhœa, from his failure to give the treatment of it proper attention, had become chronic. About the last of July, when he consulted me as to the possibility of marriage, I told him that so far as syphilis was concerned there was no reason why he should not marry, but so long as there was the slightest discharge from the urethra, this feature would debar his union. Proper treatment was then instituted and carried out rather more earnestly by the patient. In August there was some improvement, and he was still more anxious to get married. I suggested to him the advisability of having a microscopical examination made, and he was accordingly sent to Dr. Vissman with instructions to take a sample of urethral discharge when he had not cleaned out the urethra for several hours, so that the discharge could be examined. This was done, and at my request Dr. Vissman made a very careful examination, and made the following report: That while there was possibly very little danger, a few gonococci were still present, and he did not think immediate marriage was advisable as he did not consider it safe to take the risk. We then worked even more vigorously in the matter of treatment, and by the middle of September, for a week or ten days, there had been no discharge. The treatment was continued and at the end of September there was still no flow. By the first of October almost a month had elapsed without the slightest sign of gonorrhœa; the mucous shreds had disappeared from his urine as thoroughly as they ever disappear in anyone who has had gonorrhœa within five years. By a most careful examination the faintest traces of mucous shreds could be seen in the urine, but there was not the slightest evidence of discharge from the urethra, and there was nothing to examine under the microscope. I then gave it as my opinion that there was very little danger from his marrying; he was apparently in the best of health; he had been examined repeatedly for stricture, which so often follows gonorrhœa, but nothing of this kind could be found, and there was no trace of the previous chronic gonorrhœal infection.

He married early in October and (of course) pursued the usual course in those cases. November passed, and late in December he came to me stating that his wife had been complaining, and told me the nature of her symptoms. He said that she had only been complaining for a few days. He very wisely thought an examination should be made at once, and for this purpose his wife was brought to my office. Upon examination I found that she was suffering from undoubted gonorrhœa; she had urethritis, vaginitis, and considerable pain in one side, with slight pelvic peritonitis. She has been under treatment since that time; she still has vaginitis but no urethritis, and the urine has become normal. There are still some evidences of pelvic trouble in the left side.

I cite these two cases for the following purposes: In the first place we have been taught that specific urethritis runs a certain course. It has probably not been the experience of anyone here to take a case of undoubted specific (so-called) gonorrhœa, such as was present in the first case and cure it in four or five days. I remember once of having a case where I thought I was producing a remarkable result in curing a gonorrhœal discharge in eleven days with resorcin. With that exception, I can remember no case of specific gonorrhœa that was cured inside of three to four weeks. Now, that being the case, the question is, did this man (unfortunately we did not have the secretions examined) have a specific gonorrhœa? If so, then it was cured in four or five days by remedies that have not been certain to effect a cure heretofore inside of twenty-eight days. If he did not have *specific gonorrhœa* how could he have given his wife gonorrhœa? It is fair to assume that this man has had intercourse with his wife quite a number of times since she has gotten better, and he has not developed any form of gonorrhœa.

In the second case the man had no discharge whatsoever from the urethra for several months previous to marriage, and has had none up to this time, and yet his wife developed an undoubted case of gonorrhœa so far as all symptoms are concerned, because there is no form of simple vaginitis which will result in urethritis and pelvic peritonitis. I never had this woman's secretions microscopically examined.

---

## GOUT AND THE TEETH.*

HENRY BURCHARD, M. D., D. D. S.

This paper as originally written was titled "Diseases of the Teeth with which Medical Men should be Familiar." Since, then, I have seen in the *Transactions of the Pennsylvania State Dental Society* an article by Dr. Brubaker, which deals at length with the question of reflex disturbances having origin in disease of the teeth. In view of the existence of that able paper, it would be idle to attempt extensive addition.

There are two things, however, which are worthy of the respectful consideration of every physician or surgeon. By far the most common cause of trigeminal neuralgia is some disease of the teeth. This may be the exposure of hyper-sensitive dentine; an irritation or inflammation of the tooth-pulp; any degree or type of pericementitis; and retention of fragments of teeth after attempts at extraction. To these must be added encysted teeth, or those which have such malposition that eruption is deferred or impossible.

The dentist alone is familiar with the number of cases of trifacial neuralgia, spasmodic closure of the jaws, etc., which find relief through dental ministrations.

There is too much disposition among medical men to view teeth as little more than possible signs of hereditary syphilis, and the cause of gastro-intestinal disturbances in children; beyond this the majority of physicians do not concern themselves. This does not apply to specialists in ophthalmology and rhinology; they frequently consult with the dental practioner for possible sources of irritation in and about the teeth.

Dr. Brubaker quotes Galezowski, "that he always examines or has examined the teeth of his patients."

*Read before the Philadelphia County Medical Society, by invitation of the Board of Directors, April 11, 1894.

Certainly the most eminent men of the medical fraternity recognize what an important part the peripheral irritation, arising from dental diseases, plays in the causation of other and more serious maladies. Everyone is of course familiar with the work done by Dr. Miller, of Berlin, in dental bacteriology. There is another subject for consideration to which he calls attention—the number and variety of pathogenic organisms which find an ideal breeding-place in the human mouth. All the pyogenic cocci; those of septicæmia, of pneumonia, of actinomycosis, etc.

The more dental disease remains uncorrected, the more flourishing the colonies of these organisms.

Another matter, simple to be sure, but one in which eminent medical men have frequently erred—the distinction of diseases of the dental pulp and of the tooth's periosteum. The pulp of the tooth is not its tactile portion; it is rather that of special sense, the thermal; for thermal changes are about the only cause of response in the healthy pulp. The tactile function resides in the tooth's periosteum, the pericementum.

Teeth which respond to concussion, or pressure, have the pericementum, not the pulp, affected; in these cases the pericementum will be found dead, decomposing, or absent. *Vice versa,* those which respond to thermal change, as a jet of cold water thrown in the cavity, have the pulp affected. In the latter case, sedatives, warm syringings, and stopping are in order; in the former such measures would serve to increase the difficulty through retention of irritating materials; they require antiseptic washings, such as 15-volume solution of $H_2O_2$.

After marked pericemental inflammation, abscess usually supervenes. All counter-irritation in these cases should be in the mouth, localized over the gum of the affected tooth. In these cases much damage is done, even to-day, by the use of poultices.

There is a disease of the dental periosteum which has for years attracted much attention. It is known as pyorrhœa alveolaris, or better termed phagedenic pericementitis. This disease is the cause of the loss of as many, if not more, teeth than dental caries. As the name implies, it is a progressive destruction of the tooth's periosteum. Erosion of the teeth is another disorder known to dentists.

The purpose of this paper is to point out the association of these disorders with the uric acid diathesis, and their striking likeness to gouty affections.

So much confusion has arisen during the discussion of papers on this subject, all due to conflicts of definition, that two will be here premised as bases to work from. They form the reason for such opinions as are here enunciated. Stress is laid upon this matter, as it is desired to point out the probability of these dental disorders being accepted as pathognomonic of the gouty disorder. Whether gout be unquestionably present or even suspected, it is confidently believed by the writer that the dental symptoms are conclusive evidence of a condition akin to, or identical with, the gouty; that its three stages—tooth induration, altered secretion of glands, and degeneration of pericementum—are expressions which receive value as diagnostic signs in the order named, representing the earliest, the stimulative; the second, the irritative; and third, the inflammatory stages of the gouty diathesis.

The uric acid condition is one arising through faulty metabolism, causing the production and retention in the circulating fluids of an excess of uric acid; followed by changes of tissue degeneration or those arising from the presence of a constant irritant in any member of the connective-tissue group. This leaves open the all-important question of the exact origin of the waste product. According to all authors, heredity plays the important part as a predisposing cause. An ingestion of an undue amount of nitrogenous food, or the increased consumption of malt liquors or heavy wines is the exciting cause. Prominent among the attendant disorders is fermentative dyspepsia, a complexus of symptoms known as portal engorgement, cirrhosis of the kidney, and subacute or chronic inflammation, or rather irritation in any of the fibrous structures.

*For dental diseases.* Dental erosion is a progressive loss of tooth substance through a process of decalcification, a chemical solution of the lime salts of the teeth, evidently not associated with dental caries, and which the therapeutics of caries does not check. Its action is largely confined to those portions of the teeth in contact with the labial and buccal mucous membrane.

Phagedenic pericementitis is a degeneration of the retentive apparatus of the teeth which arises without mechanical violence, specific virus, or the selective action of drugs, and proceeds to its termination with or without the formation of calcic deposits and true pus (although the pus and deposits are usual associates), the process terminating with the loss of the teeth. It is unusual to preface the pathology of a disease by its clinical history, but it will be more clear in this instance. The teeth attacked are dense and hard; the variety which resist the causes of dental caries. Men and women are alike subject to it. As a rule the disease is evident only after the patient has attained an age of thirty or over. Although it does exist in some cases before that age, its occurrence is unusual.

There are two types of this pericementitis, depending upon the portion of membrane first attacked. The more common, and as some erroneously suppose, the only type, begins as a marginal gingivitis. The earliest symptom is a deepening of color and a softening of the gum tissue at the neck of the tooth. The inflammatory appearance increases, and by the time the case receives attention the close attachment of the gum to the tooth at this point is lost. Pockets are thus formed in which are found concretions, and pus is oozing or may be pressed from the pouches. This process continues; there is degeneration of the pericementum; an inflammatory degeneration, or a molecular necrosis; increased deposits of lime salts are found as the denudation of the tooth's root proceeds. The attachment of these teeth lessens particle by particle, thus adding another source of destructive irritation, undue mobility. One by one, they lose their retentive apparatus, the pericementum, and are extruded, cast off as foreign bodies. This ends the process; there is no tendency toward extension to the maxillary periosteum. At the utmost this may be destroyed at the edges of the alveolar process and we have a slight amount of molecular necrosis at that point in consequence. The deposits are usually hard and scaly, strongly adherent. In contradistinction to the ordinary salivary calculi, they are found beneath the gum, not on it.

The disease either persists or recurs despite all local therapeusis. It is this more than for any other reason that the disease has been ascribed to a constitutional cause. As for the dental erosion, we find in teeth of good structure a loss, particle by particle, of the enamel, and after this the dentine. This is in such situations that the ordinary solvent, lactic acid, produced by the action of microorganisms is in least amount. This is the essential difference between erosion and caries. The process is usually seen when one of the superior anterior teeth is attacked. Commonly a groove or grooves may be seen, caused by a loss of enamel upon the labial faces of one or more of these teeth. The amount of enamel surface (that containing the greatest amount of inorganic matter) affected is greater than that of the dentine. This is the reverse of the process of dental caries. These spaces of denudation are in such situation, and of such shape, as to exclude any cause except that arising from altered secretion of the mucous glands about the parts. Dr. E. C. Kirk, the editor of the *Dental Cosmos*, who has devoted much time to investigations as to this condition, has found an almost constant association of it with gout.

In most cases a history of heredity and acute outbreaks. If the patient had not yet been the victim of gouty disturbance he or she did become so, sooner or later. This is for disease with an incipient expression in mucous structures.

Cases are recorded of teeth in which the tissues about the necks of the teeth are intact; and yet, disassociated from any of the usual causes of pericementitis, we see evidences of a localized inflammation of the pericementum somewhere between the apex of the root and the neck of the tooth. The disease area spreads until there is a destruction of the entire pericementum and the tooth is lost. These cases may show no evidence of the formation of true pus until near the end, when microorganisms gain entrance through a loss of continuity of the tissues at the neck of the tooth.

Dr. Kirk has in his possession a lateral upon which there is a destruction of the apical half of the pericementum and much of the cementum; the remainder of the membrane was intact. In this necrotic area, and near the apex, was a deposit—a calculus evidently formed in the pericementum, for its attachment was so slight that it was lost. This prevented chemical analysis.

The deposits taken from these teeth have been analyzed. While some give the murexide reaction, certain others, with a clear history of gout, show not the slightest trace, being composed of phosphate of lime.

All local causes having been found insufficient to explain the course and phenomena of this particular disease, a constitutional disorder has been deemed a necessary condition for its existence. The persistence after removal of local causes assures us in such a position. Search has been made among general diseases for one which would produce a degeneration of articulative tissue with an accompaniment of crystalline deposits. In the practice of medicine but two such diseases are known—rhuematism and gout—including here as close associates of gout, rhuematoid arthritis and lithæmia. The pathology of rhuematism does not explain or agree with that of phagedenic pericementitis. We are thus driven by a process of exclusion to viewing gout as the predisposing cause. The question now is, Will the pathology of gout explain every stage of the dental disease?

Gout is hereditary in a large proportion of cases; not that this or any other disease, except in a few rare instances, is inherited, but regarding heredity as an expression of the transmission of a type of tissue. That women, who are not commonly the subjects of gout, are the victims of phagedenic pericementitis, is not an argument against gouty origin; for rheumatoid arthritis is the form assumed by hereditary gout in the female (Da Costa).

In the individual who has such a family history there is a predisposition to the formation and non-elimination of an excess of waste material of nitrogenous origin. It is rational to conceive this process as one of gradual growth; although decided manifestations of the morbid influence of the retention of these waste products do not assert themselves before middle life, the predisposition exists, and the disease process probably extends over a period before becoming recognized, the body at large resisting the morbific influence until the power of combating it is lost at some weak point or points, and the disease asserts itself. Its effects may be so insidious that our means of discrimination are insufficient to discover any aberration from an ordinary healthy standard. Like any other general irritating substance, it may be present in any amount; all other conditions being alike, the effects are in direct ratio of the amount. Results of the action of these pathogenic materials would be most evident in peripheral parts—that is, situations where there is a scarcity of blood vessels surrounded by fibrous tissue, the least vascular parts being the first to suffer. According to the degree of irritation, we may have any stage of vascular perversion, from a slight increase in the flow of blood to the stasis which precedes necrosis; in the celular elements, any stage from the stimulation which promotes constructive metamorphosis to the paralysis resulting in coagulation necrosis.

The most important of all questions relating to this matter is the exact mode of production of these waste products. Until it be ascertained whether this is an expression of faulty food metabolism or of an incomplete retrograde tissue metamorphosis, we are in the dark. Again, what part may be performed by the excretory organs and the oxygen-carriers of the blood. We may suspect the blood corpuscles to have a close relation, as there are splenic changes present. Apropos of this, the thyroid gland and bone-marrow should also be involved; otherwise we have grounds for the formation of further hypotheses as to the physiology of the spleen.

It is by no means clear what influence the liver has in the production of gout. One would infer from a reading of some of Lauder Brunton's works that he suspected that organ to be largely at fault. It is presumed that any body—any crystalline substance—resulting from causes similar to those producing uric oxide would have analogous action. We know that xanthin, or, as it has been called, urous oxide, does form nuclei of cystic calculi.

Inflammation of fibrous structures arising from such source are, perhaps, more common than supposed or conceded. The presence of an irritating product, such as uric acid, even in slightly increased amount, could produce widespread disorders of a not severe type, and render inexplicably obstinate many disease processes usually amenable to treatment.

For purpose of comparison as to the active diseases, general gouty condition,

and marked phagedenic pericementitis, Ebstein's theory fits best. It is a nutritive disturbance first, leading to necrosis; and urates are deposited in the necrotic area.

For the minutiæ of the dental trouble, first, the unusually hard and dense teeth, very commonly the subjects of pulp calcification. Accepting the uric acid diathesis to be a condition long existent, there will be for some period present in the circulatory fluids an excess of the irritating waste product, uric acid. From this there will be strictural alterations in peripheral parts. Stimulation of the peripheral cells of the dental pulp is followed by an increased deposit of calcic material, necessarily lessening the amount of organic matter present. The density of the dentine increases; its vital parts decrease. This may continue until scarcely any vestige of vital matter is left within the teeth. They become of the variety which resists dental caries. The cirrhotic process affects the parts about the teeth; the alveolar process increases in density; the thickness and elasticity of the pericementum decreases. In this connection it would be a matter of great interest to note the structure of the teeth in young patients who have a family history of gout.

At a period during or approaching middle life, the gouty condition being present, it will manifest itself in one of two ways, the intensity of the action depending upon the amount of irritating material present and the amount of resistance offered by different tissues. Altered secretion is regarded as a milder form of disorder than tissue change. Function, in the majority of cases, is altered before structure. The presence of waste material will cause, in peripheral glands, irritation during its elimination. There are numerous mucous glands in the labial and gingival mucous membrane. These may secrete an acid capable of acting as a decalcifying agent upon the lime salts of the teeth; this would explain the phenomena of erosion.

Function is in correspondence with structure; teeth of this type are designed for hard, vigorous usage. From their structure they are exposed to two probable sources of debility; one, that they may become through their lessening vascular supply of the nature of bodies foreign to the structures which support them; the other—it is questionable if, in civilized life, 90 per cent. of persons give their teeth sufficient use in view of this fact; for teeth of this description doing the amount of work their structure demands is out of the question. More than this, gouty patients are frequently gourmands, and indulge in food requiring little mastication.

Disuse and misuse are two prominent sources of debility in any part of the organism. The vital parts of such teeth will, therefore come to a state of agony through disuse. Their resistive power to morbific agents will be weakened. Disease attacks preferably a weak part; rather, a weak part permits the existence and growth of the causes of disease. According to the evolutionist definition of life it is questionable whether a perfectly healthy part can become the subject of disease. These organs are, therefore, in fit condition for the development of disease process, through their acquired debility.

The teeth and their attachments to the alveoli form articulations; the pericementum is the periosteum of the tooth's root, and the ligament which binds it to the bony walls enclosing it—the type of tissue for which the gouty poison seems to have selective action.

According to Ebstein, the gouty process is essentially necrotic. This is in marked gout, but there must be every stage of vascular disturbance antedating the necrosis. According to the degree of irritation will be the effects. Every medical man has seen gouty attacks, ranging from a slight metatarso-phalangeal arthritis to ths variety accompanied by excruiating pain, followed by deposits in the joint. So with the teeth, the phagedenic pericementitis may be an inflammatory degeneration or a necrosis of the fibrous—in fact, of all the articulative tissue. The waste matter is now in amount sufficient to produce structural degeneration. An early angiomatous change will be a swelling of the intima; this, in small vessels, will markedly impede, if not check the flow of blood. The tissues are starved, and to the extent of innutrition there will be either inflammatory degeneration or molecular necrosis.

For the deposits, preceding their formation, there is an acid reaction in the necrotic area; the blood having lessened alkalinity, through the presence of an ex-

cess of uric acid, a substance insoluble in acids meets the acid tissues and uric acid or urates are deposited. As before mentioned, the tests for uric acid did not always, nor frequently, demonstrate that substance to be present in the dental deposits. These, as analyzed by Dr. Kirk, are frequently found to be phosphate of lime. It is probable that a small crystal of a urate has acted as an irritating point around which the calculus has formed. The deposits at the necks of teeth, just beneath the free margin of the gum, do not resemble ordinary salivary calculus, or the deposits which are found near the apices of the teeth. Their probable origin has a close connection with the secretion of the mucous glands, which lie just within the border-line of the gum. As the disease progresses these encroach more and more into the area of necrosis, or their presence forms the continued irritation which determines the persistence of the disease.

As before stated, there are cases where we have no visible signs of pus. If the disease begins at the gum margin pus is probably always formed; the analogous phenomenon of gout is the tophic abscess. Several pathogenic cocci have been isolated, but there is absolutely no evidence that the disease has such a cause.

For a summing up. There is a dental disease for which local explanations as to cause do not suffice. George B. Wood, Niemeyer Garrod, Duckworth, and Bartholow, among medical men; Marshall, Peirce, Kirk, Jack, and others, among dentists, note the association of the disease with gout; in very many cases a clear history of heredity and acute outbreaks. Search has not been thorough in certain instances to determine whether or not obscure gout be present. Other cases show decided evidence of lithæmia. After the removal of all visible sources of local irritation the disease of the teeth either presists or recurs after some lessening of the severity of the local symptoms.

Some of the cases recorded by the dentists named are as follows: The teeth of certain individuals, with or without a definite history of gout, become susceptible to periosteal irritation, even an inflammation, and this in the absence of the usual local irritants.

The ingestion of an undue amount of nitrogenous food or heavy wines is followed by one of these attacks of pericementitis. Upon a withdrawal of these substances from the dietary, there is a disappearance of the local inflammation.

There is but one deduction from this: the disorder must be due to faulty metabolism.

We have a local inflammation, due to the formation and retention of what should be waste product; and what more is gout?

There are two elements—one a faulty metabolism; another, the organs of excretion do not functionate properly. As far as we have evidence, the latter seems to be the element which determines an attack of gout.

Faulty metabolism might, and no doubt does, cause the formation of incomplete oxidation products, and these excite disorders of a mild type in many, very many persons; but it is only when the organs of elimination have reached and passed the limit of their function that weak parts give way, and an explosive attack of gout results.

There is no reason why any member of the same group of substances might not play the irritant role; xanthin or urous oxides, uric acid or uric oxides, in excess they are both irritants. Pathological chemistry certainly gives but meagre account of the origin of both substances.

In about 75 per cent. of cases of true phagedenic pericementitis, dentists give an unfavorable prognosis, and despite all local measures of therapeusis results justify such an opinion.

This fits Ebstein's theory of gout, the process essentially necrotic. In any disease a prognosis is favorable to the extent to which cause may be removed and effects remedied. Both these objects are difficult or impossible of attainment thus far in the dental disease.

As for the question of therapeutics. A condition in which there is altered secretion, necrosis of certain connective tissues, with a consequent undue mobility of the teeth, the presence of necrotic material, and more or less of foreign bodies; added to these, the continuance of a predisposing cause which is also acting as an excitant. The indications are, of course, the removal of all the causes; a cure cannot be effected while any of them persists. All dead and foreign materials are to be removed. All bacteria to be destroyed,

and their further action made difficult or harmless. Faults of occlusion are to be remedied; loose teeth so fixed by splints that rest of the loose organs is assured. Local vascular disturbance is to be controlled. This is as far as local measures can be carried, and the daily experience of dentists demonstrates it to be insufficient.

General treatment involves the correction of the secretion of glands of the parts about the teeth. This evidently can only be accomplished by a removal of the causes which give rise to the formation of incomplete waste products.

The gastric and intestinal catarrh must be corrected; as the gastric disturbance is of the fermentative type, a lessening of the amount of carbohydrates in the dietary is quite as important as modifying the type of the nitrogenous ingesta.

Many of the cases gave evidence of the condition known as portal engorgement. Whether affection of this organ is the primary cause of the faulty metabolism, is a question of the utmost importance. The changes in fibrous structures at large, such as in the tissue beneath the bronchial and pulmonary epithelium, in the connective tissue of the kidney, etc., are not within the province of our special therapeutics. Certainly the general indication is the elimination of the retained, irritating waste product. How else does colchicum act? Many symptoms are relieved by producing an increased alkalinity of the fluids of the body. In some situations concretions are removed through the solvent action of lithium salts, but it is out of the question to hope for such a result with dental deposits. The tartrate of potassium and sodium is one of agents used for the double purpose of producing alkalinity of the circulating fluids, and as an eliminant through the *prima via*. This fact has suggested to Dr. Edward C. Kirk the advantages of replacing one of the bases of this tartrate by lithium; a lithium Rochelle salt is the result. The virtues possessed by this compound over the usual lithium salts and the officinal Rochelle salts is evident. While it performs the office of the tartrate in bringing about an increased alkalinity of the blood, there is added the uric acid solvent, lithium. It has a mildly laxative effect. Where it has been tried there has ensued a speedy amelioration of the annoying symptoms of lithæmia due to clogged excretion.

Dr. Bartholow calls attention to the value of manganese salts in the treatment of the gouty condition. This aids first in a correction of the gastric disorder, and secondly, as in the case of permanganate of potassium, increases the oxidizing function. Iron should, therefore, be doubly useful in the anæmia of the gouty diathesis. In this connection, is it not possible that certain obscure maladies, relieved through the inhalation of oxygen, may be cases of obscure gout, masked lithæmia?

---

In a public address in England Lord Coleridge told an anecdote of Browning that gives an interesting glimpse of the poet's self-appreciation. Browning sent the jurist a copy of one of his later books of poems, and when he asked for an opinion of it was told frankly, "What I understand I heartily admire, but there are parts which for the life of me I can't understand." "Ah, well," replied Browning, "if a reader of your calibre understands ten per cent. of what I write, I think he ought to be satisfied.—*New York World.*

---

Pain without fever, says a prominent physician, may be very severe, and may cause much suffering, but in acute attacks it is not dangerous. "If you had this amount of pain that you complain of," he said to a patient who had hastily summoned him, "in any inflammatory disease, you would be in a raging fever; if you have no fever you need never worry." Most serious illnesses are preceded by a chill. This is a symptom which should never be disregarded, and it is always safest to put a child to bed and stop its food. Warmth and dieting will be found to be the best remedy for any ordinary indisposition, while for the beginning of any serious trouble it is often the only thing that can be done until the disease declares itself.—*Good Health.*

## THE SACRAL METHOD FOR EXTIRPATION OF THE UTERUS.†

Dr. Hochenegg contributes some interesting facts to medical literature on the above subject. During 1885, Kraske performed a resection of portion of the sacrum in order to facilitate extirpation of the rectum; he named this method "Sacral Rectum Extirpation." Later (1888) Hochenegg and Herzfeld decided to utilize this method in selected cases for uterine extirpation instead of performing it per vaginam or by abdominal section.

Dr. Herzfeld presented a paper on "Sacral Extirpation of the Uterus" at the Gynæcological Congress held at Breslau, May, 1893, which called forth a lively discussion, and in which the majority of German gynæcologists opposed its adoption.

Hochenegg, in this present contribution, is anxious to prove its usefulness in certain selected cases, and reports from his practice 25 cases in which the sacral method was used to extirpate carcinomatous uteri; in most of these the disease was so far advanced that extirpation *per vaginam* would have been impossible; there were four deaths due to the operation.

A collection of other reported cases found in medical literature number 98, with a total of 18 deaths, or a mortality of 18.3 per cent.

The convalescence is somewhat prolonged (6 to 8 weeks) in comparison to other methods. The points in favor of the sacral method are: That the field for operation is more accessible; any bleeding vessel can be readily and securely tied; the large blood vessels are easily isolated and tied, and the ureters avoided. Many cases which are hopeless for the vaginal method can often be radically removed by the sacral method,—for instance, such in which the bladder and intestines have become implicated, or such where isolated carcinomatous deposits could be found in the parametrium, or fibroids and ovarian tumors necessitated removal.

In a contracted pelvis or vagina in which there is a carcinomatous uterus with pyo-salpinx or ovarian abscess, the sacral method permits of greater accuracy and facility in their removal.—*Med. Neuig.*, No. 15, 1894. W.

## SYPHILIS TREATED BY INTRA-VENOUS INJECTIONS OF SUBLIMATE.

Prof. Baccelli highly recommends this form of treatment after having given it a fair trial in the clinics as well as his private practice, particularly in such cases in which the ordinary methods have produced little or no curative effects. The solution used by him contains the following:

℞ Hydrarg. Bichlor..... 1 0.
Sod. Chlor..... 3.0.
Aq. Dest... ..... 1000.0.

The skin is thoroughly disinfected, and the veins made prominent by previous bandaging, the needle of a hypodermic syringe is introduced into the selected vein and the fluid injected. The cure begins with one daily dose of one milligramme or one cubic centimetre of the 1: 1000 solution. This is increased to 2 3-4-8 mgrms.

The author gives the following reasons for the adoption of this method as an improvement on others:

1. The necessity of using the smallest dose necessary to effect the desired cure, and which is not always achieved by the hypo- and endermic methods.

2. The possibility of overcoming rapidly such symptoms due to direct blood poisoning from the syphilitic virus.

3. The prompt and general action upon the walls of the blood vessels, which is a particularly favorite seat for syphilitic changes.—*Med. Neuig.* 1894. —W.

THE Modern Pawnshop: Give the devil your time and he will lend you trouble.

## TREATMENT OF ECLAMPTIC ATTACKS IN CHILDREN.

The child should be placed in bed, the room thoroughly aired, a careful examination made with a view to finding the cause; a mixture of a teaspoonful of salt, 3 or 4 of oil to one glass of lukewarm water, used as an enema; if the mouth can be opened it is well to touch the fauces with the feather edge of a quill, and give a quickly acting purgative. Should the attack continue in its severity, the following mixture is used as the first was:

℞
Mochi..... 0.2.
Camphor..... 1.0.
Chloral Hyd..... 0.3—1.0.
Vitell..... 1.
Aq. Dest..... 150.
M. Sig. Used as an enema.

Also a mustard bath, quarter to half hour; during severe convulsions chloroform may be carefully administered; between the attacks absolute rest is indicated and the administration of the following mixture:

℞
Zinc. Ox..... 1.0.
Hydrarg.....
Valerian.....āā 0.5
M. ft. Pulv. Div. in part equal No xii. Sig. Two powders daily before meals.

—*Med. Neuigkeit.* No. 15, 1894. —W.

If thy foe be as small as a gnat, fancy him as large as an elephant.—*Ex.*

## THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

### MEDICATED TENTS FOR CANCER OF THE UTERUS.

Dr. Ch. Jennings (*La Semaine Médicale*, No. 23, 1894) recommends the employment of a medicated tent of the following composition, in treatment of cancer of the uterus:

℞

| | | |
|---|---|---|
| Methyl Blue, Tannin.....āā | 25 | (grs. iv). |
| Powdered Opium..... ..... | 05 | (grs. ¾). |
| Olive Oil.....xv gtts | | |
| Cacao Butter.....45 | oo | (ʒj ¼). |

Sufficient for one tent. Introduce one every day into the cervical canal, keeping it in place with a tampon.

### LACTIC ACID IN TUBERCULOSIS OF THE BLADDER.

Dr. Witzach (*Hospitals-Tidende*, No. 10, 1894) speaks highly of instillation of a five per cent. solution of lactic acid in patients with tuberculosis of the bladder, especially in those cases where an operation offers but little hope of improvement, or is refused. He has employed this treatment in five cases; in three of these there was a remarkable improvement, while in the other two the action was less pronounced. In order to prevent the pain of instillation he later came to use a combination of lactic acid and cocaine—cocaine lactate—which is a syrupy fluid. Twice a week he instilled a gram—fifteen drops—of the following solution:

℞

| | | |
|---|---|---|
| Lactate Cocaine..... ...1 | o | (grains xv). |
| Lactic Acid ..... | | |
| Distilled water.....āā....5 | o | (ʒj ¼). |

### A TONIC PILL.

In the (*Revue Médicale*, March 18, 1894) the following formula is presented as a serviceable tonic pill:

℞

| | | |
|---|---|---|
| Extr. Cinchona | | |
| Extr. Kola, .....āā 5 | o | (ʒj ¼) |
| Extr. Rhubarb ..... 2 | 50 | (grs. xxxviij). |
| Extr. Nux Vomica ..... o | 50 | (grs. vijss). |
| Arsenite Iron ..... o | 20 | (grs. ij). |
| Powdered Kola Nut..... | Q. S. | |

Sufficient for one hundred pills. Two at each meal.

### ASTHMA.

Dr. R. v. Rokitanski (*Norsk Magazin for Laegevidenskaben*, No. 4, 1894) praises the following formula, in asthma:

℞

| | | |
|---|---|---|
| Chloral Hydrate..... | | |
| Iodide Potash .....āā 2 | o | (grs. xxx). |
| Water.....150 | o | (ʒivss). |
| Syrup Orange Peel ..... 20 | o | (ʒv). |

Two to five tablespoonfuls a day.

### ACUTE OR CHRONIC CORYZA.

Dr. L. Dessar (*La Semaine Médicale*, No. 23, 1894) recommends the following powder as a convenient and efficacious snuff, in acute and chronic rhinitis:

℞

| | | |
|---|---|---|
| Starch .....5 | o | (ʒj ¼) |
| Powdered Boric Acid.....3 | o | (grs. xlv). |
| Subnitrate Bismuth .....2 | o | (grs. xxx). |
| Menthol.....1 | o | (grs. xv). |
| Tannin..... | 20 | (grs. ij). |
| Muriate Cocaine..... | | |
| Aristol..... .....āā | 05 | (grs. j). |

**TERMS:**—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

**REMITTANCES** should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

**NOTICE TO CONTRIBUTORS:**—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 19, 1894.

## EDITORIAL.

### THE GENEROUS PROFESSOR AND THE PRODIGY'S RETURN.*

In a certain city, called the City of Brotherly Love, there dwelt many wise men and those having knowledge of the things that pertain to theology, to law, to medicine and to all things wherein men are learned.

There were also many great schools wherein was taught all kinds of knowledge.

And the fame of these schools and the wisdom of the learned men was very great, insomuch that the report of them spread abroad throughout all the world.

And it came to pass that a certain physician who was held in much esteem, fell sick of a grievous malady and was gathered unto his Fathers.

And there arose great lamentation throughout the city.

Then certain of the sect of professional philanthropists who are called promoters (for this sect professes that the relief of the needy can be done in none other way than by assisting individuals, and hold themselves ever ready to be used as examples of their faith) took counsel together as to what they should do.

For they were sore distressed, crying, Woe unto us! How is the mighty fallen! And there is none to take his place.

For we have searched and, behold, there is none, no not one among all the four hundred who wear the phylacteries, who can fill the sandals of him who is departed.

And they rent their raiment and put on sack-cloth and ashes and cried aloud exceedingly.

Then there arose one among them, and spake unto them saying: Men and Brethren hearken unto me. Why sit ye here mourning. Arise now, put off your sack-cloth and clothe ye yourselves in your right minds if, peradventure, ye have any.

Know ye not that the present is a great time for professional philanthropy?

Ye say, and ye say truly, there is none among the four hundred who have the phylacteries who can fill the shoes of the departed.

But verily I say unto you there is one who dwelleth in a far country which is

* Fragment of a record exhumed from a modern tumulus.

famous for the greatness of its inhabitant's footgear, who is willing to put on these shoes if he is able.

For I say unto you he is a Prodigy.†

Now, therefore, let us send unto him and beseech him to come and dwell among us and wear these sandals, that we may no longer be bereft.

And if so be that he is not able to put them on, behold there is at hand a retreat wherein he may be fed and clothed until such time as he be grown to fit the shoes.

Thus shall we aid the needy and show forth the glory of philanthropy, that all men may know that of Faith, Hope and Charity—the greatest of these is charity, which suffereth long and is kind, and covereth a multitude of "skins."

And they all agreed together, marvelling much that one of their number could so devise, for professional philanthropists are not accounted wise or learned.

And they indited epistles to the Prodigy beseeching him to come and help them, saying, All charges will be paid at this end.

And they sent the letters safely by servants of the government.

And it came to pass when the letters were delivered unto the Prodigy, that he read them and gave heed unto them.

And he took counsel with himself saying, Lo, here is a snap! Behold, I have dwelt in this land these many days, waiting to build sandals large enough to wear in years to come and have not yet secured an estimate.

And behold, I am entreated to go hence and, in an ancient city, wear the greatest pair—for so he had been told.

Moreover, all charges are prepaid, and there is a mansion waiting wherein I may reside the while these shoes are being half-soled and heeled.

Now, therefore, I will arise and will go unto that city, I and all my family with me, that nothing may be left to show I ever lived elsewhere.

†Or Protégé. As is evident from the context the two words are used as synonyms in the original.

And he arose and did as he had said.

Now it came to pass when he arrived in the City of Brotherly Love, that great misfortunes came upon him because that the professional philanthropists, though endowed with shrewdness, had not commonsense.

For it so was that the sandals which had seemed so mighty unto them, were far too little to be worn by many men who deemed it shame to wear phylacteries.

Likewise they reckoned without cause, in that the Rulers of the chosen retreat would none of the Protégé.

Saying, Go to! This business is not yours, nor can ye meddle with it.

Thus was the Prodigy put in sore straits, for he had not wherewith to house nor clothe himself, neither had he ought to eat or drink, save what was given him.

Now there was in that city, a righteous man of profound learning, who was also a teacher in one of the great schools of the city.

And such was his wisdom and skill and his kindliness of heart, that he was greatly beloved of all that listened to him.

Likewise, his learning was set down in books, and his name was spoken as one having authority, even in the uttermost parts of the earth.

And men came from every nation to be taught by him those things which must be known in order to heal the sick and minister to the afflicted.

And among all the great men in that great city none was mightier than he.

And it came to pass when he knew of the afflictions of the Prodigy he was moved with compassion.

For he said, Surely I have known the struggles and misfortunes of a young man. And as I was given strength wherewith to triumph in my hour of need, so will I give my aid to those who need it.

By this he showed that he was not of the sect of professional philanthropists.

So he came unto the Prodigy and taking him by the hand he lifted him out of

the mire and put his feet on solid ground.

And he entreated him well and took him to his own place.

And when he had looked upon him and found him fair to see and possessed of good parts, his heart was warmed within him, and he made room for him at his own side.

And he spared nothing to spread abroad the name of the Protégé and to make for him a place among the learned of the city.

And because of his efforts the Protégé thrived and waxed fat and, in the fullness of time, he kicked.

Then was shown a mighty wonder on the face of the earth.

For it came to pass that he whose sandals were to cover all the land, increased not in his understanding though his head swelled beyond belief.

And he took unto himself foolish counsellors who said those things they thought would please him, rather than the things of righteousness.

And he listened to them until he boasted himself there was not another such an one in all the earth.

For he said unto himself, Behold me, what I am.

For am I yet a youth or am I come to manhood? Is it not time that I should show all men my greatness?

Was I not besought to come hither and let the light of my countenance shine upon those men more foolish than myself?

Did I not come and get my foot in it?

Yea, verily, not only my foot, but my whole body and my head, yea, even to the tips of my ears.

What though I was pulled out by one esteemed so great, is not the honor of helping me sufficient reward for any living man?

Verily he hath done himself credit in honoring me, but that I may not seem ungrateful I will accord him honor worthy of the Dwellers of Olympus.

For I will accept all the great and solid glory he has built up by a life-time of righteous deeds and pure wisdom, and use it as my pedestal, which all men, viewing from afar, will think to be my work.

And I will place him on a shelf where he may see and yet remain unseen, and he shall revel in the happiness of seeing men applaud his work, believing it of me who am so great.

When he had made an end of thinking, he cast about for means wherewith to do his will.

And he gathered together certain who considered it wicked to withhold their greatness from men who wot not of it.

Certain others also who possessed talents bearing the stamp of the government which made them legal tender for all things, save only brain and conscience.

And others likewise, who had sons or kinsmen not born great nor able to achieve greatness and upon whom they desired to thrust greatness.

Others also belonging to the sect of sore-heads and growlers, together with the professional philanthropists and all the dwellers in the holy land who love to sit in the high places and be seen of men.

These then took counsel together and joining all their wants, they went unto the Rulers of the great school and demanded of them the removal of the Pitiful Professor, together with three others who are likewise men of great reputation and teachers of ability, and to give their places to the Protégé and others like unto him.

Now, therefore, if the Rulers of the school hearken to these cunning men and are persuaded of them, the meaning of this parable will be made manifest to all men.

But what think ye those Rulers———

[The record is abruptly broken at this point, and we are left to conjecture whether this fragment is a prophesy, an admonition or an allegorical statement of current events. Further research will undoubtedly supply the missing parts and develop the sequel.]

# SOCIETY REPORTS.

## THE LOUISVILLE SURGICAL SOCIETY.

*February 7, 1894.*

[Stenographically Reported by C. C. Mapes, M. D.]

### CYSTIC TUMOR OF THE ORBIT.

DR. W. O. ROBERTS: This patient is sixty-one years of age. Forty-five years ago, that is when sixteen years old, he was kicked by a horse just above the brow, receiving a compound fracture of the outer table of the skull. He says that the brow seemed to be knocked down. The attending physician told him that the inner table of the skull was no injured. The wound healed, with marked depression at the seat of the blow. He had no trouble following the injury with the exception of headache; there was never any indication of epilepsy or anything of that kind. There was some defect in his vision, and he claims that his eye on that side was pushed down somewhat.

Twenty-nine years ago while chopping wood, a stick flew up and struck him on that side of the head, two splinters being driven into the eye-ball; a large piece struck him just above the eye, and he thinks pushed up that part of the brow which was forced down by the kick of the horse. The splinters which penetrated the eye-ball had to be removed by his family physician.

Two or three months after receipt of the last blow a tumor made its appearance just above the eye and near the nose, and, as he says, it pushed the eye considerably down and as it grew larger it extended to the right side, and has attained the size which you see now, being much larger than a man's fist. There is very little vision in the eye on that side; he is able to distinguish daylight from darkness, but nothing further. There has never been any acute pain from the growth.

#### DISCUSSION

DR. TURNER ANDERSON: I think the tumor is unquestionably cystic. In regard to the origin of it there is one point of interest to me in connection with the ridge of bone passing around the tumor, which is especially plainly marked at the upper portion. Wherever the pericranium is elevated, as we find in cases of bloody tumors in the head of new-born children, where the effusion is underneath the pericranium, between the bone and the covering of the skull, the pericranium being elevated, it very soon begins to throw out a line of bone and within a few days the blood seems to be contained as within a cup, the line of bone having extended all the way around it. These cases usually recover without treatment.

In the case before us I take it that the tumor is clearly cystic; the pericranium has been elevated by the effusion, and the imperfect line of bone at that point formed before the vessels became so thoroughly constricted that new bone could not be produced.

Dr. W. L. RODMAN: The case is certainly very interesting, and Dr. Roberts should have it photographed before he operates. There occurs to me three possible views in the case: First, it is possibly a dermoid cyst, for it occupies one of the favorite regions of the body for such growths. While dermoid cysts are congenital, they very often do not make their appearance to such extent as to be noticed until advanced life. They are more common near the outer than the inner angle of the orbit, although they do not occur in both situations.

Secondly, it may be a cyst which is growing from the frontal sinus.

Thirdly, it may be a cyst growing from the bone, probably the upper part of the wall of the orbit. It seems to me this view would be the most rational and more in line with the symptoms present in this case. In any event I am perfectly satisfied that it is a simple cyst. It could not well be malignant. Its duration, absence of pain and glandular enlargement, together with the excellent general condition of the patient emphasize the innocent nature of the growth. The irregular edge I think is due to the fact that the anterior or outer table is gone. I believe that the bone will be found necrotic. It is a simple cyst; probably dermoid in nature, either beginning at the angle or the roof of the orbit, and I believe operation should be performed at once.

There is another possible view of the case, which, however, is hardly probable, viz.: a sub-dural cyst. I operated upon such a case occurring in a negro boy at the University Clinic in 1889, Dr. Ray assisting me. Both the cyst and eye were removed and the case made an excellent recovery.

DR. J. M. RAY: It seems to me that the starting point of the growth before us is in the frontal sinus. The history of the growth beginning at the upper and inner angle growing toward the outer corner, looks very much as though the probable origin was in this local-

ity. Fatty tumors about the orbit are quite common, both congenital and otherwise. I have seen several such cases.

DR. A. M. VANCE: I do not think the growth before us is cyst; the contents seem to be semi-solid, and I believe it commenced in the orbit proper, from the history. I believe the orbit will be found to have melted away, also the bone above it has given way allowing the tumor to grow upward.

I do not see why it may not be malignant. I know that I have removed sarcomata from the head of people who looked just as healthy and in just as good condition as this man presents, which had been growing almost as long. I am inclined to think that this growth, if not originally malignant, is at present. I believe its contents is not fluid, but semi-solid. I certainly recommend its removal.

DR. W. O. ROBERTS: I have very little to add in closing. There is some question in my mind whether it is a cystic tumor, or a myxo-sarcoma. I think it comes from the orbit, and I told this man when he came to my office to-day that I thought it would be advisable to first aspirate the growth to ascertain the nature of its contents. It does not make any difference what it is, I propose to remove it. Myxo-sarcoma is about the slowest in development of any of the sarcomatous growths. It is not improbable at all, I think, that this is a dermoid cyst. I think it began in the back of the orbit, and did not show itself until after receipt of the last injury. I do not believe, however, the injury had anything to do with its occurrence.

---

### A LARGE SARCOMA OF LEFT KIDNEY IN A CHILD FIVE YEARS OLD—NEPHRECTOMY—RECOVERY.

DR. W. O. ROBERTS: The first of last December I was called to Shelbyville, Ky., to see a child who will be five years of age the coming April. The history of the case was about as follows: The mother stated that four weeks prior to my visit, she noticed that the child's abdomen was much larger than it should be, and, examining it she discovered a tumor considerably larger than a man's double fist. The child had never complained of any pain or discomfort in any way. The mother was led to make the examination simply by the prominence of the abdomen.

While running about four days before my visit, the child had fallen flat on his face. He then commenced complaining a great deal about his abdomen and was put to bed. At the time of my visit his temperature was 100° F., and had been so for three days. There was considerable pain and tenderness over the left lumbar region; the child was lying in bed with the legs drawn up. Upon palpation, it was questionable whether there was fluctuation or simply elasticity of the tumor. I suggested that we aspirate to see whether the growth contained any fluid; this was done at three different points and nothing except a little blood secured. I then made the diagnosis of malignant disease of the left kidney. It was thought by the physician who had seen the case previously that the patient had disease of the spleen. I made my diagnosis chiefly upon the tympanites along the region of the colon.

I did not see the child again until the latter part of December. At that time the tumor had grown considerably; it filled the whole left side of the abdomen down almost to Poupart's ligament, and extended over about two or three inches to the right of the median line. The case was brought to this city for operation, and on January 17th, at the Norton Infirmary, assisted by Dr. Anderson and a number of other gentlemen, I made first a short exploratory incision—a perpendicular one—for the purpose of settling the diagnosis as to the organ involved; it proved to be the kidney as I thought. The spleen was perfectly normal as to size, but was pushed up, of course, by the growth. In this exploratory incision there was an opening made in a little vein on the surface of the tumor which bled very freely, and it was with difficulty the hemorrhage was controlled. I had explained to the father before making the exploratory incision that if the tumor was found of such a character that it could not be removed without too great a risk, the abdomen would be closed. When the bleeding occurred from the punctured vein, I, with the father's consent, went ahead and removed the tumor.

I did the operation suggested by Abbe, whose paper I had a day or two before seen in the *Annals of Surgery*, which consists in opening the abdomen transversely instead of perpendicularly. The short incision made was about two inches, I suppose, to the outer border of the left rectus abdominis muscle. I then carried the other across the abdomen one inch below the ribs back to the lumbar region and across the outer border of the rectus; that brought me down directly upon the growth. We found the descending colon so closely adherent that it was with some difficulty we were enabled to detach it. When we had dissected down to the pedicle of the tumor, the child seemed so nearly dead, that I did not take time to pick out the ureter but tied off the body *en masse*. I found that the tumor grew from the fibrous covering of the kidney, only a portion of the kidney seeming to be involved in the growth; the kidney, however, was removed in its entirety, as I was afraid the other portion might be infiltrated, and which could not be detected at the time. After removal of the

growth the wound was closed by three lines of continued sutures; it had to be done very rapidly owing to the extreme condition of the patient. The peritoneum was brought together first, then the muscular structures, then the skin and fascia. The child was put to bed in almost a moribund condition; however, he rallied and went along to recovery without an untoward symptom. He was discharged from the Infirmary yesterday in good condition, with the wound healed. The tumor which I exhibit for your inspection, was found to weigh immediately after its removal seven and a half pounds.

DISCUSSION.

DR. TURNER ANDERSON: I want to congratulate Dr. Roberts upon his success in this case. I think it was the most formidable surgery that I have ever witnessed. Dr. Roberts kindly permitted me to assist in the operation. The transverse incision extended around almost to the spinous process of the dorsal vertebra so that everything was thoroughly laid open. The adhesions to the descending colon were very extensive; the tumor was also adherent to the peritoneum and had to be dissected off. The whole procedure required the most pains-taking careful surgical work that I have ever witnessed.

DR. W. L. RODMAN: I also wish to congratulate Dr. Roberts upon the successful result in this case. It is the second case of nephrectomy he has had. I assisted him in the first case several years ago. The incision suggested by Abbe is perhaps a very good one; it certainly affords greater access to the kidney than the ordinary incision in front but it strikes me as being questionable whether this incision of Abbe is better than the older operation very much like it; that is, the operation of König, in which he begins posteriorly and cuts anteriorly. The only difference is that Abbe goes through the peritoneum, while König does not. König dissects up a large flap of the muscles and when he comes to the peritoneum it is pushed forward toward the median line, in that way he removes the kidney without doing injury to the peritoneum. The disadvantage in either operation would be the great liability of ventral hernia. While the result in Dr. Robert's case is very gratifying so far as the primary result is concerned, I am very clear in my own mind from statistics on the subject that these operations are done more to show what can be done with the knife than for any real substantial good that comes to the patient. Gross and others have shown very clearly that the mortality of nephrectomies for malignant disease is frightful; in the lumbar operation about thirty per cent., in the abdominal operation about forty-five per cent. One reason why the abdominal is perhaps more fatal than the lumbar operation is that severe cases are operated upon by the anterior route; you cannot remove as large a tumor by the posterior as by the anterior route. So when you consder that the mortality in these cases is forty-five per cent. further, that no single case of cancer of the kidney has ever passed the three years limit after operation and that very few sarcomas have passed this limit; that many of them die on the table; others dying a few months after the operation; again, the liability of ventral hernia occurring it strikes me as being very questionable whether this operation ought to be done or not.

DR. H. H. GRANT: I agree in the main with what Dr. Rodman has said in reference to operations for the condition under discussion, but in this case it appears that great benefit has been done to the child by the operation, and its life is probably prolonged. If this tumor is really a sarcoma, it is barely possible that the child will entirely recover, although as Dr. Rodman says these operations have not been done very frequently for sarcoma. I believe it is possible in some cases to cure sarcoma of the kidney by complete removal. Several cases are recorded of the prolongation of life and addition of comfort after such steps.

With respect to the post-peritoneal operation for a condition of this kind: Although I have never had an opportunity to see an operation of this character performed it seems to me that in the majority of cases where a tumor of this size is present, it would be almost impossible to remove it without doing injury to remove it without doing injury to the peritoneum, and as at the present day we feel but little hesitancy in invading the peritoneal cavity, it is perhaps just as well to bodly open it as suggested by Abbe, and understand in the beginning just what we were cutting without fear of after results from invading the peritoneum. It seemed to me when I read Abbe's paper that it would not be an unwise thing to make posterior opening through the lumbar region at the time, which would allow thorough drainage and still not disturb the decubitus of the patient. It seems to me this would be an important additional step in the operation, and I believe if I had occasion to do an operation of this kind I would supplement anterior drainage by making drainage in that region.

DR. W. O. ROBERTS: As Dr. Rodman says this is the second case I have operated upon for malignant disease of the kidney, the first one being in 1885. This patient was referred to me by Dr. Anderson, who also rendered valuable assistance in the operation, and in that case there was recurrence of the trouble and the patient died inside of three months.

However there was prompt recovery from the immediate effects of the operation. Regarding the mortality in these cases: Statistics show that about fifty per cent., according to Abbe, die from the immediate effects of the operation. I think Keyes reports a case that lived four years after operation.

In my second case when the operation was undertaken, the father was advised of the opinion of all the gentleman present that it was almost certainly a sarcoma; we told him that if we found it to be a sarcoma and thought it best not to go on with the operation because of that fact, we would simply close the wound; but when the troublesome hemorrhage occurred I saw it would not do to close the wound, hence after consulting with the father, went ahead and removed the growth.

Referring to Dr. Grant's remarks concerning drainage: I will state in this case drainage was made from the posterior angle of the wound, with strips of iodoform gauze put down to the bottom of the wound which drained very satisfactorily. This was removed at the end of forty-eight hours, and another small piece introduced which remained until the second dressing, then no further drainge was made. I think the operation as performed in this case decidedly best where the tumor is large.

The advantage of incision at the outer border of the rectus muscle (Lanenbeck's), over the one in the median line, is that you go through the outer layer of the mesocolon and avoid the vessels lying in the inner layer, and hence avoid the danger of sloughing of the gut. In the operation I performed in the case just reported there were no vessels to be tied.

---

SEPTIC PNEUMONIA RESULTING IN GANGRENE.

DR. W. L. RODMAN: On December 15, 1893, a young man, Mr. E. H., aged twenty-eight years, while working on the Louisville and Jeffersonville Bridge, fell with a span of the bridge a distance of rather more than one hundred feet. He was not able to say whether he was struck by any timbers or iron in falling. He received a fracture of the fifth, sixth and seventh ribs of the left side. The shock was quite profound but he recovered from it with reasonable promptness. It was noticed at once that one of the ribs must have penetrated the lung as he spat blood copiously with each expectoration, and air could be felt in the cellular tissue over the fracture. This became more marked during the day until the whole side of the chest was quite distended with air, which also passed down the left side of the body; the scrotum was especially distended being as large as a child's head. He got along very well for three days never having a decided rise in temperature, suffering only at times from short, painful paroxysms of coughing. On the fifth day there was an elevation of temperature, it reaching a point as high as 104° F. That was the beginning of as severe a case of traumatic pneumonia, which was, of course, septic in nature, as I have ever seen. The left lung was solid from apex to base. He had a hard time getting over the pneumonia, but on the fourteenth or fifteenth day he showed symptoms of improvement; the temperature remained very high, hardly ever less than 104° F.; there was no effusion in the pleural cavity. On the sixteenth day his temperatnre dropped somewhat, and he commenced expectorating a great amount of very offensive matter. It was so extremely offensive that it made all the nurses and patients sick. It was necessary to keep all the windows open, although the weather was quite cold. There was evidently gangrene of the lung, he soon went into a condition of profound sepsis, and I had very little doubt but that he would die. While the temperature was low he had at all times a very copious sweat, the pulse became very frequent, 130 to 140, the skin had that peculiar muddy appearance of sepsis, and he was in a very critical condition. A consultation having been held, it was thought advisable to resect his rib and to see if we could not find the original opening in the lung, and following that as a guide open up the abscess in the gangrenous part of the lung. This was done, I think, about the twentieth day after the accident. The sixth rib was resected, a piece about four inches in length being removed. I used the Rongier forceps, which, by the way, I shall always use hereafter, as I consider it the best instrument for the purpose. Pus was encountered as soon as the rib was cut; the original opening in the lung was easily detected, and a large abscess was found in the gangrenous portion of the lung. The lung was packed with several yards of gauze in strips, and the man's recovery has been very gratifying indeed. He was better the day after the operation and has improved steadily ever since. The abscess was in the upper lobe of the left lung. He spat up the foul stuff for a week after the operation, some of it drained out through the incision, and for the last month he has seemed to be perfectly well. He is able to walk about the Infirmary, is gaining flesh and strength, and altogether his convalescence has been very satisfactory. Pus was discharged from the wound for three or four days; after that time the discharge was only from the superficial part of the wound. It was packed every day for about eight or ten days and then allowed to heal.

DISCUSSION.

DR. TURNER ANDERSON: I was very much interested in Dr. Rodman's report. As we understand pneumonia, I have been under the impression that such a thing as *traumatic pneumonia* was impossible. We may have an abscess or inflammatory process involving the lung, but a veritable *traumatic pneumonia* as we understand pneumonia, is hardly admissible. Of course, the treatment in these cases is plainly indicated as soon as the abscess is detected, as soon as the lung becomes gangrenous—to practice external drainage.

In this connection I wish to claim priority in the matter of practicing external drainage in pneumonia, as I believe I was the first to attempt such a procedure in this part of the country. The case was one of ordinary pneumonia which terminated in gangrene of the lung; it was a severe case in which I aspirated the lung, then enlarged the opening and practiced external drainage between the ribs. The rib was not resected, and I believe that in many of these cases free drainage may be obtained, without removing a portion of the rib, by making an opening in the inter-costal space and inserting a drainage tube.

DR. W. O. ROBERTS: I also wish to congratulate Dr. Rodman; certainly he carried out the proper procedure. The patient was in a very critical condition, and the doctor is deserving of great credit.

DR. T. S. BULLOCK, (Visiting): I have seen with Dr. Anderson two cases similar to the one under discussion, where recovery followed very promptly. In the first case after aspirating, a drainage tube was passed through the intercostal space and thorough drainage established in that way. In the other case he did a resection of the rib and recovery followed promptly. I must say that I never saw such an amount of pus escape from any cavity as was discharged in the last case.

DR. JAS. S. CHENOWETH: I was present when Dr. Rodman operated upon the case referred to. While the patient did spit up a large quantity of very offensive stuff, I was particularly struck with the small amount of pus liberated at the operation. I was rather impressed that there might possibly be a collection of pus which was not reached; however, the patient was very promptly relieved, and it is evident all the pus was removed. I was struck with the small amount of pus and the very grave symptoms.

DR. J. G. CECIL: I want to ask one question in reference to puncture of the lung by a fractured rib. As I understood the reporter, it was evident from the beginning from the symptoms already detailed that the rib had been fractured, and that it had wounded the lung. Would it not have been good surgery therefore to have made an incision in the region of the fracture as soon as the man recovered from the shock of the accident, and searched for the rib which probably projected into the lung? It occurs to me that this would be good surgery, and might have prevented after trouble such as Dr. Rodman has described.

DR. W. L. RODMAN: I am glad Dr. Cecil has brought up the question of early operation in these cases, and the point he makes is an excellent one. I was tempted to make an opening in this case the second day after the injury. I went over all the literature of the subject very carefully and could find nothing to warrant me in such a course. The books simply state, "In case of depressed ribs, where you are satisfied the lung has been injured, the proper procedure is to take a blunt hook and go down into the rib and aim to pull it up in that way." I did not believe any good would come from such a procedure, so did not attempt it. The next case of the kind I have I shall not hesitate to do as Dr. Cecil suggests; certainly it is the proper procedure in such cases, and there is no danger in removing a piece of the rib, when it is already as in this case a compound fracture, air entering from within.

In regard to the point made by Dr. Anderson: I am perfectly familiar with the fact that the larger majority of medical writers say that we do not have *traumatic pneumonia*. I do not mean to say that in these cases we have the *pneumococcus*, but I do say that this man's lung was solid from apex to base. Another man hurt the same day who is still in the Ward, had the same kind of an injury, although he has not had emphysema and the lung did not become gangrenous, but it was solid from top to bottom—evidently a septic pneumonia. I am thoroughly convinced that any man examining the two patients would have pronounced one lung of each perfectly solid from top to bottom; whether it was pneumonia or not, you can decide for yourselves,—each had the rust-colored sputum, the characteristic respiration, pulse and temperature of pneumonia, and neither at any time had any fluid in the pleural cavity.

DR. W. O. ROBERTS: It is not unusual to have an injury of the lung and fracture of the rib without an abscess; Dr. Chenoweth will remember a case that we exhibited before the class at the University not long ago, where the man had a fracture of the second rib with emphysema. The man recovered without the slightest trouble and without operation.

I do not think it advisable to do this operation in fracture of the rib until there is evidence of suppuration.

DR. W. L. RODMAN: If you knew there was a penetrating wound of the lung, do you not think it would be good surgery to operate at once?

DR. W. O. ROBERTS: Just as soon as there

was evidence of suppuration, then operation should be performed, not before.

---

Dr. I. N. Bloom read a paper on

URETHRITIS—SIMPLE AND SPECIFIC.

(See page 705.)

DISCUSSION.

DR. H. H. GRANT: I do not speak of these cases from a specialist's standpoint, but it occurs to me that both cases Dr. Bloom describes may be easily explained. In the first case I believe that his patient most certainly had simple urethritis, and it is entirely possible for simple urethritis to have produced this irritation in the woman. I am sure that I have seen a number of cases of urethritis which were simple in the male, certainly cases in which there were no gonococci present; perhaps in many instances there was certain irritation, the result of old strictures producing long-standing trouble, that infected the wife afterward; and while I believe, as Dr. Bloom states, that it is not possible to bring about a cure for gonorrhœa in four or five days, yet I do think it possible for simple urethritis to get well in that length of time to all appearances, and yet afterward may cause vaginitis, urethritis, etc., in the female.

Referring to his second case: A great many cases of gonorrhœa are supposed to be cured while there still remains in the glands, far back in the prostatic portion of the urethra a quantity of the gonococci which are not in active irritative and aggressive condition, yet they are present and may become disloged and pass out with the urine or with the semen in sexual intercourse, and in the latter case they are ejected into the female vagina and may be productive of serious trouble. I think there is almost no question about this being the course of infection in the second case reported by Dr. Bloom, and I can see no other rational explanation of the first one. I am sure Dr. Bloom will say without hesitation that a very large number of cases of gonorrhœa are apparently cured, still there may be retained somewhere, either in the epithelial covering of the urethra or in some of the glands or pockets far back, germs able to cause gonorrhœa for a very considerable length of time, even after all manifestations have apparently been cured, and this, too, without there being any particular irritation in the male, or at least any irritation that he is able to define as result of the urethritis. Certain symptoms are nearly always present in individuals who have suffered long from gonorrhœa which remain for a considerable period of time, certainly for a year or more after apparent recovery; the patient feels a sense of discomfort in the prostatic portion of the urethra almost invariably, and sometimes even higher up there is that condition known as gonecystitis. It is exceedingly common for conditions of this kind to exist long after the original trouble has disappeared.

DR. J. G. CECIL: The cases reported by Dr. Bloom are very interesting to me. Certainly we know it to be a fact that gonorrhœa may exist for a long time in the genital passages of women, in the glands of Bartholini, in the cervix, in the posterior vaginal fornix, and in many places almost inaccessible which generally are overlooked or neglected in any method of treatment that is adopted. The question as to how long gonorrhœa may exist either in the male or female, and how long it may possibly be communicated is one to which I have never been able to give any satisfactory answer, and shall be very glad if Dr. Bloom, in closing, will enlighten us in this particular.

I can hardly agree with Dr. Grant that simple vaginitis will show up in as virulent a form as indicated in the case reported by Dr. Bloom. We may have simple vaginitis occasionally, but I have never seen it involve the urethra to any extent. I have seldom seen it extend to the pelvic region and involve the tubes; in fact I hardly think it is probable that simple vaginitis will ever result in these complications. I am free to say that I can not understand how the first case described by Dr. Bloom could have originated. The second case, especially in its relation to the time when it is advisable for persons to marry after having had gonorrhœa, strikes me as being one of very great moment, because of the prevalence of gonorrhœa among young men, and especially since we know the wonderful number of diseases in the female that result from so-called cured gonorrhœa. I had a case in mind at the time Dr. Bloom was speaking, of a gentleman whose wife had been suffering from some womb trouble, who had, of necessity, to live apart from his wife and had indulged his fancy outside contracting gonorrhœa. He came to me for treatment while his wife was going to another physician for treatment. I persisted with and urged upon him the necessity of complete cure before he again went to stay with his wife, and thought that I had accomplished this, and he thought so, too. Every symptom had disappeared, and he went so far as to make a crucial test by going outside again and trying it on somebody else, and utterly failed in his attempt to communicate the disease. Three or four weeks after all symptoms had subsided he communicated gonorrhœa to his wife.

It is a question that it seems to me ought to be settled in some definite way if possible, because of its importance. Of course no man wants to communicate gonorrhœa to his wife, whether she be newly married or otherwise, and especially since we know that so

many pelvic diseases which require extensive operative procedure to relieve are due to gonorrhœa, it seems to me the quesion ought to be discussed and settled. I am sorry that I have not something definite to offer, but it seems to me that Dr. Bloom in the cases he reports did follow out every possible precaution that even the most exacting of us could have asked, and yet his cases went wrong. The question will come up to all of us, When can a man marry after he has had gonnorhœa with safety? When should he be allowed to marry?

DR. I. N. BLOOM: I feel very much gratified that the cases I mentioned have been so thoroughly and ably discussed. My object in citing these two cases was to get the different opinions on the subject. I am fully cognizant of the experiments and tests that have been made as to the cause of gonorrhœa, and as yet I am not satisfied and not prepared to state that the germ of Neisser is not the specific germ of gonorrhœa; on the other hand I am also not prepared to state positively that it is the essential germ which produces gonorrhœa.

As regards the first case: Dr. Cecil has answered Dr. Grant exactly as I should have done. I do not believe simple urethritis could possibly produce the symptoms which were seen by one of the physicians present who was called in consultation when peritonitis developed.

In the second case, the man married early in October and had intercourse with his wife during October, November and a part of December before she developed any symptoms of gonorrhœa, and the strangest feature is without a single symptom developing in himself. It is natural to suppose any latent urethritis that might exist would be aggravated by sexual congress the first few weeks of marriage and be at once communicated; I believe that is the usual history of these cases. However in this case nothing in the wife until fully two months after marriage. Some writers claim that a man may be absolutely free from all symptoms for a year, and then communicate gonorrhœa; while such cases may sometimes occur, I believe they are extremely rare. Further, do not some authorities recommend marriage for the cure of so-called gleety discharges in the male, and have not cures resulted in some cases, without any trouble developing subsequently in the female? Yet here is a case where exactly the opposite condition exists—there was absolutely no sign of urethral discharge for a period of several weeks before marriage, all evidence of gonorrhœa having disappeard, yet the wife became infected. We could all cite cases where a discharge was still present, the patient married became well, and the wife was not infected. I do not believe that the gonococci can exist in any part of the urethra for along time sufficiently active to give a specific gonorrhœa to anyone, without causing trouble, and specific trouble at that, in the patient himself.

I am satisfied the cases I have reported might be multiplied by many others, and because of the importance of the subject I think they are worthy of discussion and publication. In regard to the specificity of the bacillus of Neisser—I do not think it has been fully established, clinically at least.

DR. BODINE (Visiting): I understood Dr. Bloom to say that his patient had at one time what was regarded as specific urethritis, that the gonococci were present. Is it not possible that some of these gonococci invaded the ejaculatory ducts, during the progress of the urethritis and there remained quitely, producing absolutely no trouble?

By treatment may we not destroy all the the gonococci in the urethral tract, but may not some of them during the active stage get into the ejaculatory ducts and remain there? No examination of the urine in such a case, no matter how frequently repeated would disclose their presence, but during the ejaculation of semen in sexual intercourse they might be transmitted to the female. I can understand how this might occur, and simply offer this suggestion as a possible explanation of the infection in the case reported by Dr. Bloom.

DR. I. N. BLOOM: The tendency of the gonococci is to increase and multiply, and I believe all experiments in this direction show that they never lie in a latent quite condition, but are continually developing.

DR. H. H. GRANT: I agree perfectly with what Dr. Bodine has said, and simply rise to answer Dr. Cecil: In the present history of diseases of women, am I not correct in saying that there are certain authorities who maintain that no woman ever marries a man who has had gonorrhœa but suffers in some way from the effect of that gonorrhœa?

There is abundant authority in every surgical journal of the land, and in nearly every surgical book to support the statement I made that gonnorrhœa is not by any means cured when the discharge ceases and that in many instances the disease remains latent for a very considerable time. Therefore if it be true, as maintained, that any woman who marries a man who has had gonorrhœa invariably suffers from its effects, it would seem to me that if a man marries a woman within a period of two or three years after he has apparently recovered from an attack of gonorrhœa, it is perfectly possible for the gonococci to produce such effects as Dr. Bloom has described.

The question as to when it is safe for a man to marry after having apparently recovered from an attack of gonorrhoea is one of the greatest importance, and one which in my opinion is far from being satisfactorily settled.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D., AND SAMUEL M. WILSON, M. D.

THE MEDICAL CHRONICLE

of Manchester, England, for April. Dr. Julius Dreschfield contributes a paper on a

**Peculiar Form of Idiopathic Intermittent Fever of Pyæmic Character.**

The author states that there can be little doubt that the disease is microbic in its origin. He saw in all six cases, they were all men, their ages varying from 23 to 56. All, with two exceptions, had enjoyed good health up to the time of the onset of the disease—one had suffered for some time from the symptoms of alcoholism, and one had had glycosuria for several years before the febrile attack set in. Not one of them had lived in a tropical or malarial climate, nor had any of them ever had malaria, rheumatic arthritis, or any injury. In four out of the six cases the disease was fatal.

The principal symptom noticed in each was a pyrexia, not unlike that seen in intermittent fever—namely a rigor, during which the temperature would raise to 103° F., and sometimes to 107° F. This was followed by the hot stage, and this was succeeded by the stage of sweating; the perspiration, in some of these cases, was so profuse that the clothes of the patient, and even the bed clothes, were soaked through and had to be changed.

The pyrexial attack was followed by a febrile period, during which the temperature was normal or subnormal, and during which time the patient felt quite well. In some of the cases the temperature between the rigors was somewhat above the normal, but yet the patient did not appear to suffer any inconvenience. The rigors occurred in a few cases regularly once a day, generally in the evening, in other cases they occurred at very irregular intervals. Sometimes there were two or three rigors within twenty-four hours, at other times there was no rigor for several days. This irregularity occurred in the same patient.

Abdominal pain was present in three out of the six cases from the first. The pain was not localized nor did it occupy the same position in all; in two it was over the region of the liver, in one over the epigastrium, and in the fourth a mild diffuse pain was felt over the abdomen. In some the appetite remained good throughout, in others there was occasional vomiting, and in one persistent vomiting; constipation was present in all. In none of the cases was there noticed any affection of the lungs or heart. The pulse was steady and slow during the febrile period, and rose quickly to 100 and more during the fever stage. The spleen was found slightly enlarged in all cases. The urine showed little that was abnormal; in only one case did the author detect albumen and hyaline casts in the urine, which was passed about one hour after the sweating stage, and this occurred several times in the same case. The diazo-reaction was absent in the three cases in which it was tried. An important and noteworthy symptom in three out of the six cases was an enlargement of the liver; but this came on some time after the onset of the disease. Two of these cases terminated fatally (in one of them very slight jaundice appeared a few days before death), and the liver was found to be the seat of suppurative hepatitis. In the third case jaundice came on about six weeks after the onset of the disease, the liver enlarged enormously, but after a time both the liver intumescence and the jaundice gradually disappeared, and the patient made a satisfactory recovery.

Though the prominent symptom in all was the intermittent fever yet the author is certain that the cause was certainly not due to malarial poison, for the patients did not live in a malarial country, and none of them had ever had malaria; the spleen was only slightly enlarged, and increased in size only with the progress of the disease, and quinine, arsenic, and even methylene blue, had no effect whatever on the pyrexia, nor did the attack of pyrexia show any periodicity. In support of the view that the disease is of pyæmic origin, the author cites (1) the suppurative hepatitis which was found in two of the fatal cases; and (2) the relation of the disease to some pyæmic affection, namely, pylophlebitis and ulcerative endocarditis. (3) The presence of numerous micro-organisms in the liver in one case.

The author, therefore, regards the disease as pyæmic and due to a micro-organism which probably enters the system through the digestive tract, and reaches the circulation either through the portal vein or the lymphatics. Either it, or the toxines produced by it, causes the peculiar symptoms, and if arrested in its course, say in the liver, and not destroyed there, it may give rise to suppurative hepatitis, though it is possible that if suppurative hepatitis occurs, this may be due to a second infection. The author is unable to say as to the nature of the micro-organism further than that it appears as numerous clusters of small thick bacilli which appear in close relation with the billiary passages, and in their appearance not unlike the bacterium coli commune.

In the treatment of the affection the various antipyretics, quinine, sodium salicylate, antipyrin, antifebrin and phenacetin were used, but none of them appear to have had any good effect. Large doses of quinine, and arsenic, showed no immediate effects in these cases. Methylene blue given in one case appeared to aggravate the symptoms. The recovery of the two cases, the author thinks, was due to the fact that the patients could take a very fair amount of food, and that in this way the patients had sufficient strength to resist the devastating effect of the micro-organisms, whose natural term of life eventually expired.

Thomas Jones, F.R.C.S., discusses

**Cancer of the Rectum and its Treatment by Excision.**

In cancer of the rectum, as in cancerous affections generally, it is of the utmost importance that the condition should be recognized before the disease has made much progress. The early symptoms are often insignificant, the patient perhaps merely complains of vague pains in the rectum, or notices that he is becoming more and more constipated. The author impresses the great need for a more regular and systematic examination of the rectum whenever the symptoms point, however indistinctly, to disease situated in that region. Little good can be effected once the affection has involved the tissues outside the wall of the gut. The necessity for a rectal examination in every case of persistent diarrhœa must ever be in the mind of the surgeon.

When the new growth is nodular and very extensive, often almost encircling the gut, the passage of feces will be seriously interfered with, and obstruction may at any time arise. Glandular enlargement may take place late in cancer of the rectum—a fact of considerable importance in regard to the question of operation. The examination, which should be carried out with care and gentleness, is to elicit information on the following points: The character and extent of the disease, and the condition of the rectum as regards mobility upon the other pelvic structures. In this manner is to be settled the question as to whether the disease has travelled beyond the limits of the intestinal wall, and on this hangs the propriety of attempting to remove the disease by excision. It is also possible by digital examination to determine whether the lymphatic glands are enlarged or not; those in the hollow of the sacrum, when enlarged, may be made out through the wall of the rectum.

The author divides the operations for the relief of rectal cancer into two classes: (1) those that aim at the relief of urgent symptoms, and (2) those that have for their object the complete removal of the diseased mass. Among the former, colotomy offers the best prospects. It not only relieves the sense of weight and uneasiness in the part affected, and removes all chance of obstruction, but checks the progress of the disease, and places the patient in a state of comparative comfort. In regard to the question as to whether this operation should be resorted to early or only when the symptoms have become well established, the author states that he is against waiting until the disease has made serious inroads upon the patient's strength. Removal of the cancerous growth by the free use of the scoop or of the fingers may relieve the spmptoms of obstruction, and should perhaps be adopted when other means are not available, though this and linear proctotomy have little to recommend them.

The radical cure of rectal cancer can only be effected by free excision from the perineum, but if the operation is adopted indiscriminately it is certain to fall into disfavor. The merits of each case, as it presents itself to us, must be carefully weighed, and only those cases operated upon in which there is a reasonable prospect of removing the whole of the disease. Before a final decision is arrived at, the rectum must be explored while the patient is under the influence of an anæsthetic, and attention directed to the following points: The extent of the disease and the state of the rectum in regard to mobility in the pelvic space. Regard must also be had to the general condition of the patient with respect to strength and nutrition; his age; as to whether there is any evidence of the disease affecting parts outside and adjacent to the rectum; also, whether there are any symptoms to show secondary deposits in the liver or elsewhere.

The author considers the objection to Kraske's method of operating (by removing the coccyx and left lower part of the sacrum to obtain space for the necessary manipulations and bringing the rectum down to the skin surface) is not founded on any substantial basis. Cripps objected to this on the ground that it favored the production of pockets outside the rectum, in which decomposing fluids might accumulate, but the author has brought down and fixed the entire circumference of the rectum, or a considerable portion of it, and has never witnessed any ill effects from the practice.

In regard to the condition of the patient after the operation and the prospect of a complete cure, the author says that his condition will compare very favorably with that obtained by colotomy, and is infinitely preferable to that in which a patient with advanced cancer finds himself. In most instances the patient recovers sufficiently to enjoy life, and even to resume active work, and it is possible that the disease may not show itself locally, but return in some internal part where its ravages are less dreadful to witness. Besides this, the moral effect of total removal of the disease cannot be overestimated. With regard to the possibility of complete cure, the author quotes the statistics of Cripps: In nine out of twenty-three cases the disease recurred after periods varying from four months to two years, but six remained well after intervals which varied from two to four years.

The author closes his paper with an earnest appeal for early diagnosis. If the disease is allowed to travel outside the limits of the gut the only chance of obtaining relief is by colotomy. To perform excision under these circumstances is to put the patient to needless pain and discomfort.

W. J. Sinclair, M. D., discusses

**Ventrofixation of the Uterus.**

The author believes that the bad result in those cases where the uterus is reported as having returned to its original position was due to the operator having used too few stitches to keep up a permanent connection between the uterus and the abdominal parietes. It is of valuable assistance in the operation, he thinks, to seize the fundus uteri exactly in the middle with a sutiable small volsella, which can be held by an assistant, and the uterus can thus be drawn by him in the

direction which is most favorable to the completion of any necessary manœuvre. An important point in the operation is the introduction of sponges behind the uterus, immediately on its being drawn forward. by the volsella; these clear the field of operation and prevent injuries of the intestines or any manipulation of them. A drainage tube has been used only when it was necessary to tear down considerable adhesions which might be expected to bleed. The external dressings, when no tube was used, consisted of lint soaked in carbolic acid and glycerine. This was covered with gutta-percha tissue, and occasionally above the tissue is placed a soft flat sponge. The dressings are then kept in position by strapping. The sponge keeps up a gentle elastic pressure, and is not too thick to interfere with the advantages obtained from the use of an ice bag when reaction appears too strong. As it is essential to keep the patient lying on her back at first, the author has invariably introduced a glycerine-pad pessary of the Hoge shape to support the uterus until the adhesions might be assumed to be firm and permanent.

The author reports a number of cases and ends his paper with the following conclusions:

1. The various published series of cases show that the element of danger is almost *une quantite negligeable*. The present writer's series supports this opinion.

2. The operation, efficiently performed, is a permanent cure of the troubles arising from chronic retroflexion of the uterus, complicated with adhesions or inflammatory affections of the tubes and ovaries.

3. When pregnancy occurs after the operation no distress is experienced by the patient, and no unusual phenomena are observable during the pregnancy, parturition, or the puerperal state.

4. Contrary to what might be expected, bladder troubles are quite the exception after the operation, and these discomforts are almost certainly avoidable by care in operating.

5. In a certain proportion of the cases ventral hernia occurs at the site of the cicatrix. How this is to be prevented is one of the problems of the future.

6. After making full allowance for the element of risk and the incidental drawbacks, the operation of ventrofixation is not only justifiable, but is indicated in a certain limited class of cases of retroflexion of the uterus with complications.

---

THE EDINBURGH MEDICAL JOURNAL

for May contains the conclusion of the paper by John Wyllie, M. D., on the "Disorders of Speech," this number dealing with "Dysarthric and Anarthric Disturbances of Speech due to Lesions Affecting the Motor Speech-tracts" especially the lesions in the second trophic realm. There is also a second instalment of the "Morison Lectures on Insanity" delivered by John Batty Tuke, M. D.

Francis D. Boyd, M. D., contributes a paper on

**The Relative Proportions of the Two Proteids in the Urine in Cases of Albuminuria.**

As the result of many observations made by him in cases of acute nephritis, chronic interstitial nephritis, amyloid disease of the kidney, albuminuria of pregnancy and albuminuria of heart disease, the author comes to the following conclusions:

1. That in albuminuria both the proteids of the blood and serum are present as a rule, but there are certain exceptional cases where this does not hold.

2. That we cannot diagnose the form of kidney lesion from the proportions of the two proteids in the urine.

3. That the proportions of serum albumin and globulin may vary widely in albuminous urine.

4. That even in amyloid degeneration, where the patient is very emaciated, the globulin may not be in excess.

5. That in the albuminuria of pregnancy, both serum albumin and globulin are present, the tendency being for the globulin to be in proportionally large amount.

6. That in the albuminuria of heart disease, where there is no chronic kidney disease, the globulin is usually in larger proportion than is commonly found in chronic interstitial nephritis.

7. That in acute nephritis, where there is no hæmaturia, the serum albumin and globulin are, as a rule, about equal to in proportion; but when there is blood in the urine, the globulin is proportionally large in amount.

J. Ryland Whitaker, M. D., contributes a note on

**The Relations of the Axillary Artery.**

Quoting from Quain's Anatomy, the author states that the usual description given is as follows:—"First part of the axillary artery—The nerves of the brachial plexus are to the outer side, the external anterior thoracic nerve crosses in front, and the internal and posterior thoracic nerves behind. Second part.—The three cords of the brachial plexus are placed one on the outer side, the second behind, and the third on to the inner side." The author makes quotations from other works on anatomy with all of which he finds fault in that they make no mention of the passing of the inner cord of the brachial plexus behind the artery. According to the author, the relations should be stated as follows: "The cords of the brachial plexus lie to the outer side of the first part of the axillary artery, and at the junction of the first with the second part, the inner cord passes behind the vessel and gets to its inner side, so that in the second part of the course of the artery the cords of the brachial plexus lie, the outer cord to its outer side, the posterior cord behind, and the inner cord to its inner side."

A. G. Miller, F. R. C. S. E., reports a case of

**Acquired Tubercular Disease of Hip and Shoulder Joints.**

The patient, whose case is reported at great length in the paper, had been nursemaid for six weeks to an intensely tubercular child. The girl herself had a good family history and had previously been healthy, without

any suspicion of tubercular disease. At the end of the six weeks she developed tubercular disease of the hip and shoulder, and finally of the lungs. Pus from the affected joints was found to contain tubercular bacilli. The girl died a year and nine months after the commencement of the disease. The author accounts for the infection thus: "The girl being a considerable part of the day with the tubercular boy, feeding him, kissing, washing and dressing him and his sores, must have inhaled, and possibly swallowed, a considerable number of bacilli. In some way which we do not perfectly understand, these bacilli passed into the circulation, and were thus potentially in every part of the girl's body. From the cold and damp of the room in which she slept (the season being winter) she acquired an arthritis, probably of a rheumatic character. This arthritis affords an opportunity for the establishment of a colony of tubercle bacilli which, at first slowly in the shoulder joint, and then more acutely in the hip joint, carry out their usual work of destruction. Later on they establish themselves in the lungs, and produce a fatal issue."

The author acknowledges that it is always very difficult to prove direct infection. In this case he claims that at least the presumption is very strong that the nursemaid acquired her tubercle from the child she had charge of. He publishes the case because he thinks that sufficient care is not always taken to prevent such unfortunate events occurring, and because many are not aware of the risk.

A. Lockhart Gillespie, M. D., presents a review of "Recent Gastric Literature," and Allen Thompson Sloan, M.D., contributes a paper on "The Geographical Distribution of Goitre."

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## THERAPEUTICS.

### The Subcutaneous Infusion of Common Salt for Acute Anæmia.

Dr. O. Feis (*Therapeutiche Monatshefte*, February, 1894) reports three cases of extreme anæmia after abdominal surgical operations, in which the injection of common salt was apparently the means of saving life.

The instruments for subcutaneous infusion are perfectly simple. All that is needed is a tolerably strong canula, a rubber tube, and a funnel.

The infraclavicular region is the best place to make the injection; the skin and all instruments are disinfected in the usual way, the skin raised in folds, and the needle, with the salt solution flowing (to prevent the introduction of air) inserted. From a moderate height the fluid is let flow, the funnel being kept full. If too much collects under the skin, it is stroked away with a gentle massage.

In from ten to fifteen minutes one quart may be infused in this way. The place of the puncture is finally closed with sterilized cotton batting, fastened with sticking-plaster. Drs. Feis and Schwalm have prepared pastilles of chemically pure salt, which physicians may have always at hand.—*Therapeutic Gazette.*

### Valerianate of Amyl.

Blanc (*Rev. de Therap. Med.-Chir.*) describes valerianate of amyl, which is the odoriferous principle of the apple,—that is, the essence extracted by distillation together with alcohol. Cider has long been believed by the laity to have some effect on calculous formations, and this seems to be borne out by the fact that valerianate of amyl really has some solvent action on tholesterin. It is a colorless liquid, of pleasant taste when taken in small quantities, and can be prepared in the laboratory by the action of valerianic acid on amyl alcohol; 1 grain of cholesterin is dissolved by 4½ grains of valerianate at 37°C. and by 8 grains at 40°C. Physiologically the action resembles that of ether, but the special qualities lie in its being a stimulant and sedative to the liver in cases of hepatic colic. It not only immediately subdues the attack, but it prevents recurrences. If the stomach is irritable, it may be necessary first to employ sulphuric ether, following this with two to three capsules of fifteen centigrammes each, given every half-hour until the crisis is past, and continued at longer intervals during the following days. In nephritic colic the drug acts as an antispasmodic and general stimulant only, but no effect is produced on the renal calculi. Muscular rheumatism is frequently relieved, and much benefit is also derived from its use during menstrual uterine contractions. As a sedative, it is of value in hysterical manifestations. Its toxic properties being very slight, as many as five to six capsules can be taken daily, but it is necessary to guard against gastric disturbance.—*British Medical Journal.*

## MEDICINE.

### Ichthyol in Pruritus.

In the vaginal pruritus of pregnancy, ichthyol has been found very useful. It may be employed in the form of an ointment, made up with lanolin. In some of these cases it has given relief where carbolic acid and cocaine have failed (*Ex.*). In the pruritus, also of diabetes, the drug has proved to be very useful, combined with fifty per cent. of glycerine.

### The Aetiology of Headache.

In a recent number of the *Revue Generale de Clinique et de Therapeutique* Dr. S. Vermel, after a thorough study of the subject, says that he is inclined to attribute all headaches to an oversensitive condition of the sympathetic nerves controlling the peripheral vessels of the cranium and brain, or to an angeioneurosis. It may be asked at once, he says, how the same symptoms, from the same cause, can be present in diametrically opposed conditions, such as plethora and anæmia, febrile and apyretic diseases, for example. The idea that the seat of pain is in the cortex has not been substantiated, for when a cortex is irritated there is locally only an hallucination of pain; the real pain is exhibited on some part of the body. Then if the attack of cephalalgia is not due to local irritation of the cortex, the seat of the trouble must be in the meninges. It is to dilatation of the vessels of the meninges, causing intracranial pressure, that the pain is due. The vascular dilatation extends to the minute blood vessels in the region of the pituitary body, rupture of which gives rise to the epistaxis from which patients so frequently suffer during an attack of headache. It is clear how this explanation answers for hyperæmic conditions, but how does it account for the same symptoms in anæmia? In anæmia there is a qualitative and not a quantitative change in the blood, the amount of fluid in the vessels remaining the same. In veritable anæmia from excessive depletion of the system, as from hæmorrhage or cholera the condition is different; but from the anæmia coincident with neurasthenia, hysteria chlorosis, and so forth, there is, so far as quantity is concerned, the same condition as in hyperæmia.

In anæmia the vessels are very prone to dilatation, producing an exaggeration of the intracranial pressure, in consequence of overexcitability of the vaso-motor centers allowing of local hyperæmias.

The author definitely states that the seat of pain in headache is always in the dura mater and not in the cortex; that the pain is provoked by the compression of the dura mater produced by increased intracranial pressure; and that this is true of all headaches, whether neuroses, or of toxic or mechanical origin—such as diseases of the brain or of the meninges, constipation, etc., or of reflex origin.—*N. Y. Med. Journal.*

### The Treatment of Sprains.

I divide sprains into three degrees, viz., a mild sprain, a severe sprain, and a sprain of a still severer character. The treatment I would advise for a mild sprain would be the use of hot water and massage by means of vaseline. For a more severe degree of sprain I would apply the same treatment, plus Martin's rubber bandage, and urge the patient to walk about; and for the third degree of sprain I would use hot water as before, and a plaster-of-Paris splint, which should not be applied until twenty-four hours after the injury.—*Internat. Jour. of Surg.*

### Lubricant for Catheters.

Castor oil is an excellent material for this purpose. It is non-irritating and tenacious. It should always be applied warm, and the bottle containing it should be frequently washed with alcohol. It can be used for silk and rubber catheters alike.—*Dr. J. M. Kitchen.*

### Antipyretic Drugs.

Dr. N. S. Davis (*Med. Age*) declares that antipyretic drugs are of value only as nervous sedative! He considers cold the best of all remedies for the reduction of temperature.

## SURGERY.

### A New Treatment of Mammary Abscess.

Tweedy (*Medical Press and Circular*) adopts Weber's method of treating mammary abscess.

An early and free incision is made in the breast, radiating from the nipple, and situated at the most dependent part of the abscess.

The finger is then inserted into the wound and the gland structure broken down. This manipulation, it is stated, will have no bad effect on the healthy tissue.

By this process several new cavities will be found, and these, in turn, are to be opened by an incision similar to the first, and the whole thoroughly douched with some antiseptic solution.

The membrane lining the several cavities is to be curretted, and the *debris* removed by a second douching.

Strips of gauze sufficient to fill every interstice of the abscess are to be steeped in a one per cent. solution of carbolic acid, and inserted by means of a long sinus forceps and probe. A large, flat sponge is then placed on the breast and tightly bandaged thereto for twenty-four hours. After this period the dressings are removed, and without further irrigation the cavities are again packed, the sponge and bandage being reapplied as before.

On the third day the process is repeated.

In the fourth dressing the gauze packing is dispensed with and the incisions are drawn together and dressed antiseptically; the sponge and bandage are reapplied.

This last process is repeated every twenty-four hours until healing is complete; this usually takes place about the tenth day. In one of the author's cases the whole process was accomplished without the aid of anæsthesia. In only one of his cases was it necessary to make a second incision. The incisions are never longer than is necessary to admit a finger.

Iodoform gauze should be used for packing the wounds.

The author only having treated five cases, cannot say definitely what portion of the above treatment is essential, but he is strongly inclined to the opinion that curetting can be safely dispensed with.

### Intubation.

In regard to the comparative merits of intubation and tracheotomy as life-saving measures in the treatment of croup, I do not know of any stronger argument that could be produced in favor of the new procedure than a short quotation from a paper by Dr. L. S. Pilcher, of Brooklyn, during a discussion on this subject before the Kings County Medical Society (*Brooklyn Medical Journal*, August, 1893).

Dr. Pilcher, while advocating the claims of tracheotomy as the greater life-saving operation, makes the following very candid statement: "I believe that it has been my lot to be called upon to do tracheotomy for the relief of croup in a considerable proportion of the cases that have sought surgical relief, and yet during the seventeen years which I have been operating I have been called upon to do the operation but 66 times, notwithstanding the deaths from croup in our city during this period amounted to between 400 and 500 every year. On the other hand, during the past four years Dr. McNaughton has been called upon to intubate 142 times. He has been instrumental in saving 42 lives in four years, I but 22 in seventeen years, notwithstanding 33.33 per cent. of my cases recovered and but 29.5 of his." In other words, Dr. Pilcher was doing tracheotomy on an average of four times in a year, when the deaths from croup during the same period amounted to between 400 and 500.—O. Dwyer, in *N. Y. Med. Journal*, March 10, 1894.

### Pruritis Vulvæ.

℞

| | |
|---|---|
| Potassium bromide | 2 parts. |
| Lupulin | 2 parts. |
| Hydrargyri subchlor | 10 parts. |
| Olive oil | 30 parts. |

To be used as an external application.

—*Prov. Med. Jour.*

### Cough.

In severe paroxysms of coughing from whatever cause, a tablespoonful of glycerine in hot milk or cream will give speedy relief.

### Treatment of Hydrocele.

Dr. J. Neumann employs the following method, which he claims is less painful, and less likely to be followed by inflammation than other operations, and effects a cure within a shorter time. After the parts have been cleansed and rendered antiseptic, he punctures the scrotum with an ordinary trocar, withdraws the stillette, and as soon as the fluid flows out, pushes the cannula further up and leaves it *in situ* for two days, holding it in place with a cotton dressing and bandage. After removal of the cannula the swelling and redness of the skin is subdued by cooling lotions, such as led water. The author has tried this procedure in six cases, and was able to obtain obliteration of the sac without the occurrence of inflammation or suppuration.—*Int Jour. Surgery.*

### Gold Chloride in Pill-Form.

Dr. P. Carles advises administering gold chloride in the following excipient:

℞

| | |
|---|---|
| Calcined kaolin | 2 parts. |
| Calcined sodium sulphate | 1 part. |
| Water | 1 part. |

In spite of their hardness these pills are very soluble and retain their constituents unaltered.

### Bismuth in Gastric Disease.

Matthes (*Centralbl. f. inn. Med.*) has investigated, both experimentally and clinically, Fleiner's method of treating irritative diseases of the stomach with large doses of bismuth. The results of the treatment were very successful, especially in lessening pain. From experiments on dogs, the author shows that ten to twenty minutes after ingestion the bismuth sinks to the lowest part of the stomach, whereas several hours later it is found spread over and fixed to the stomach wall, being intimately mixed with mucus. Even with a full stomach a large part is also found similarly deposited. Against the action of chemical agents on the stomach wall this deposit of bismuth is most resistant. In men shortly after the ingestion of bismuth, the water used for washing out the stomach returns clear, but if later the stomach contents be expressed, bismuth with mucus is removed. Experimentally bismuth is shown to increase the secretion of mucus. To determine the action of bismuth in cases of erosion, etc., of the stomach, defects were made experimentally in dogs in the stomach mucous membrane and bismuth was then administered. In some experiments nothing particular in regard to the defect could be made out. In two experiments, however, positive results were obtained. In one an adherent crust was found acting as a protection to the defect. Sections taken from both cases showed healing ulcers. In the case of the crust, crystals were found in the granulation tissue, and proved both morphologically and by a color test to be bismuth crystals. No symptoms of bismuth poisoning occurred. Experiments thus show that bismuth adheres to the defect in the stomach wall, and that healing may take place under a crust so formed. This crust is not always found, but its occurrence once shows the possibility of it. Comparison with control animals showed that in those treated with bismuth the defects healed more rapidly. Digestion can go on while the bismuth deposit is present. If an artificial digestion, however, be shaken up with bismuth, pepsin will be carried down by the bismuth and digestion is thus hindered. The author says that both experimentally and clinically Fleiner's method of treatment is practically and theoretically correct with the exception of the question of position (in reference to the site of the ulcer), which he shows to have no influence in regard to the subsequent deposition of the bismuth.—*Provincial Medical Journal.*

## PATHOLOGY.

### Etiology of Appendicitis.

Hodenpyl (*N. Y. Med. Jour.*) holds that there are two classes of factors in the causation of acute appendicitis: predisposing, which may vary in different cases; and more active factors, of which there seem to be two distinct, but intimately associated elements: (*a*) bacterial, of which the bacillus coli communis is very probably the most important; and (*b*) the less well-defined and less understood chemical factors associated with the fæcal contents of the intestines. Of the predisposing causes of acute exudative appendicitis, stricture of the appendix is one of the most frequent. This condition though sometimes probably the result of previous inflammatory processes, is, in a large proportion of instances, the result of partial retrograde evolution, the cæcal opening, which is much dilated in the infant, gradually contracting until adult age, when it is smaller than the rest of the lumen, and sometimes much constricted. The vermiform process, like other organs which undergo retrograde evolution, is very prone to become inflamed. Again, the longer the appendix the more liable it becomes to inflammatory changes. Other predisposing causes are adhesions drawing the appendix into abnormal positions, atrophy of the mucous membrane, and concretions. The last-mentioned cause, though formerly regarded as the usual one, does not exist in more than 10 per cent. of the cases of appendicitis. The author, though led at one time by the results of his own investigations to regard the bacillus coli communis as a most important factor in the causation of acute appendicitis, acknowledges that the recent observations of Barbacci have proved the necessity of caution in attributing a too exclusive *role* to this bacterium. Barbacci has shown that perforative peritonitis is not due to the introduction of the bacillus coli communis alone, but is the result of (1) the escape of fæces and intestinal gases into the peritoneal cavity; (2) the development of other forms of bacteria therein; and of (3) the constant irritation arising from the continued escape of intestinal contents.—*British Medical Journal.*

### For Myalgia.

For the relief of myalgia the *Practitioner* prescribes :

℞ Linimenti chloroformi,
Linimenti aconiti ..... .....āā f ʒ ss.
Tinct. opii.... ..... f ʒ iij.
Liniment saponis.....q, s ad f ʒ iv.

M. Sig. To be well rubbed into the painful parts.

### Nitro-Glycerine in Sciatica.

Dr. Lawrence (*Rovista de Ciencias Medicas de Barcelona*) reports the case of a carpenter of fifty-two years, who suffered for several years with sciatica. In order to alleviate the pain, he had become a morphine user, and could not abandon the habit. After trying a multitude of drugs, he gave him a 1.100 solution of nitro-glycerine, one drop three times a day, gradually increasing the dose to five drops. Relief was almost immediate, and in ten days he could resume his work, completely cured.—*Lancet-Clinic.*

## ARMY AND NAVY.

CHANGES IN THE U. S. ARMY FROM APRIL 29, 1894,. to MAY 5, 1894.

Paragraph 2, S. O. No. 86, April 12, 1894, A. G. O., assigning First Lieut. Harlan E. McVay, Assistant Surgeon, to station at Angel Island, California, is revoked. He will be relieved from duty at Fort Huachuca, Arizona, and will report for duty at the Presidio of San Francisco, Cal., relieving First Lieutenant Charles Willcox, Assistant Surgeon, who after being thus relieved will report for duty at Angel Island, California.

First Lieutenant John S. Kulp, Assistant Surgeon, is relieved from duty at Fort Sheridan, Illinois, and ordered to Fort Spokane, Washington, for duty.

First Lieutenant George M. Wells, Assistant Surgeon, will proceed to Fort Bowie, A. T., and report for temporary duty, not later than the 15th instant, during the absence on leave of Captain Jefferson D. Poindexter, Assistant Surgeon.

Leave of absence for two months, to take effect on or about May 1, 1894, with permission to go beyond sea, is granted Major Calvin DeWitt, Surgeon.

Captain C. N. Berkeley Macauley, Assistant Surgeon, is relieved from duty at the U. S. Military Academy, West Point, New York, and ordered to duty at Fort Wingate, N. M., relieving Major Washington Matthews, Surgeon, who on being relieved will repair to Washington, D. C., and report in person to the Surgeon-General for temporary duty in his office.

So much of Paragraph 13, S. O. 79, A. G. O., April 3, 1894, as assigns Major Peter J. A. Cleary, Surgeon, to duty at Fort Wingate, New Mexico, is revoked.

Leave of absence for two months, on surgeon's certificate of disability, to take effect when his services can be spared, with permission to leave the Department of the Colorado, is granted Captain Edward Everts, Assistant Surgeon.

## NEWS AND MISCELLANY.

### Mutter Lectureship of the College of Physicians of Philadelphia.

The next course of ten lectures, under the bequest of the late Thomas Dent Mutter, M.D., LL.D., "on some point or points connected with Surgical Pathology," will be delivered in the winter of 1896–97 before the College of Physicions of Philadelphia. Compensation, $600. The appointment is open to the profession at large. Applications, stating subjects of proposed lectures, must be made before July 1st, 1894, to

WILLIAM HUNT, M.D.,
*Chairman of the Committee on the Mutter Museum.*

## ORIGINAL ARTICLES.

### SUMMER DIARRHŒA IN CHILDREN.

C. F. CAMP, M. D., Barre, Vt.

No department of medicine requires more thorough study and constant attention than this. How quickly, if the least opportunity offers, our patient slips away. No disease removes more children from our midst. Scarlatina may sweep away more in a given epidemic, but it is not so constant. When the epidemic passes it seldom occurs again in the same locality for years; whilst every summer brings with its hot and sultry days of July, diarrhœa which often remains with us until October.

Depending upon no special contagion for its prevalence; relying upon no previous attack for immunity against another even the same summer, it is more to be dreaded, both from its insidiousness and constancy. No country, town or locality escapes it, indeed, hardly an individual escapes its sudden attacks, though the very old or young are the only ones in which fears are entertained as to consequences. What other disease is there that knows no bounds, owns every locality, claims so many victims each year and is given so little attention?

No disease has a greater multiplicity of exciting causes. Atmospheric changes, errors in diet, exposure, confinement to house, in fact, we might say any change favors its development.

Too little stress is laid upon this condition. Mother's are led to think the child's case needs but little attention other than care from exposure or change in diet. This may be good treatment at the hands of a physician but, as a rule, for mother's to follow alone, unaided by other advice—as an idea for physicians to advance to the laity—it is dangerous.

I do not wish to be thought an alarmist in this direction, nor would I have you say to every mother that her child has cholera infantum for the purpose of making a remarkable cure, or shield yourself in case of neglect or oversight.

I am constrained to think the larger portion of cases are the results of errors in diet, *i. e.*, in the younger class of patients. A complicated feeding-bottle is a very dangerous thing in the hands of a nursing infant. A common four-ounce bottle of the shops, armed with a small, black rubber nipple is the best suited as a substitute for a mother's breast. The nurse should wash it thoroughly every time used. In the use of this size bottle, the danger of over-feeding is lessened; the food is brought fresh every time and the habit of having a large, half-filled bottle lying in the carriage or a cradle is obviated.

Many babies are overfed, yet if they cry of stomach-ache they get another meal. After a few days of this there comes the resulting hyperemia, indigestion, catarrh, diarrhœa (summer or otherwise)—cholera infantum. It often depends upon the attending physician as to which of these diseases is applied to the poor sufferer, and often it makes no difference, the result is for the bad. Many times if the bottle, the great exciting cause, were removed, the result would be a complete cure without other treatment.

A few cases are predisposed to catarrhal disorders, and their ills will be catarrhal in nature. Fewer still there are, yet they do exist, who are affected through the nervous system, either directly or sympathetically, and when undue excitement or nervous strain is brought to bear, the bowels are the first organs to give warning.

The child with thin features, large eyes, long neck, pale flabby skin presenting a bluish tinge, predisposed to glandular diseases; one with a scrofular habit, is particularly susceptible to diarrhœa.

The subject of treatment is the all-absorbing thought. We know the cause, locations, and all else; but if unable to cure, we might as well be ignorant of all.

There is much confusion and contradiction in the journals as to the treatment of this disease. In almost every State, county, or town, there is difference in treatment. Indeed, every physician has his own specific or pet fad, and all is so susceptible to change, that one following would have to change every day. This, together with the food of proprietary medicines and foods constantly advertised in the journals, left at your office, with the recommendations of college professors appended, makes the chances of the patient exceedingly hazardous, if used.

I have often thought that in our eagerness to accomplish the very earliest cure, we too often depart from the old, rational line of reasoning in our chase after rainbow specifies, hence in my treatment, I shall endeavor to prescribe in a fashion that can be reasonably defended.

First, we see those, most of all, who are merely suffering from laxness. The secretion seems healthy enough, yet the excretion is thin and frequent—no pain—no weakness, leastwise not for many days. In these cases some mild astringent, combined with tonics, will be sufficient, as bismuth and nux vomica.

I think next frequently, and perhaps most so, we find the diarrhœa of indigestion, gastric, intestinal or otherwise. To this you can give your best and every thought, and often with small success.

In this form we find the greatest number of changes in the stools; all colors and shades. In correcting this condition success lies in the ability of the attending physician to determine the locality of the indigestion. If it be in the stomach, pepsin will do much for the relief; but very little benefit will be derived if the indigestion occurs below the stomach.

The liver, if torpid, may be improved by small doses of *mercurius vivus,* (which I like much better than chalk mixture, as it does not deteriorate). Should the liver be very active with a hyper-secretion of all the organs, resulting in copious discharges, green in color, much good is obtained in the use of the rhubarb mixtures. I have used Rhus, Soda and Peppermint; Rhus, Soda, Peppermint, and Opium. When pain was severe in the older patients, a mixture: Rhei tr., Opii tr., Menth. pip. ess., Camphor Spirits, gives best general satisfaction.

The least frequent, and most dangerous to our patients, is cholera morbus, or cholera infantum, with its attending vomiting, pain, diarrhœa, collapse,—death! This, if we treat with any success, must be treated early and understandingly.

What is the lesion? Every secretion seems impaired. The alimentary canal is a veritable sewer into which the liquids of the body are poured, altered, acrid, putrid, almost rice-water discharges, anything but normal. Here we have the chance for the utmost energy. I believe alteratives are here of the greatest benefit to correct these changed secretions. I have used with much success:

℞ Hydrag. bin. iod..... 1-160 grain.
Potass. iod..... 1-60 grain.

This is an alterative of great value, especially when the discharges are watery and light in color.

Arsenite of copper is very valuable in this connection. Camphor alone or combined with opium is of great service when there is a threatened collapse. Tonics and stimulants are indispensable. I am partial to Catawba Wine for children's diseases; think it superior to the cereal liquors.

---

Imp—Well did you get into the Garden of Eden?

Satan—Yes; I took the form of a serpent and finished up the business in short order.

Imp—How did you induce the woman to risk everlasting torment for just one mean little apple?

Satan—I told her it was good for the complexion.—*Life.*

# HYDROPHOBIA.

HIRAM CORSON, M. D., PLYMOUTH MEETING, PA.

[CONTINUED FROM PAGE 705.]

## HAVE CASES OF HYDROPHOBIA BEEN CURED?

In the Encyclopedia already spoken of and published more than a century ago, the author gives many reputed cures and preventives, every one of which was highly lauded in its day, but only two cases were reported as cured after the paroxysms commenced, and they were cases which, judged by the account of them, might now properly be placed in the pseudo-hydrophobia list.

In 1753, a woman with hydrophobia in consequence of a bite from a dog supposed to be rabid, was blooded to about fifteen ounces on Saturday, and given a two-grain pill of opium every two hours. On Sunday the pill, with sulphate morphia added, having been continued, she was bled twenty ounces. On Monday her swallowing was better and the opium and morphia continued, and twelve ounces of blood taken. By a continuance of remedies she recovered. (Page 277.) This case brought opium into great repute, giving no credit to the blood letting. Both of those means were heroically used after that time for many years, but were finally proved to be of little value.

About the same time, 1753, Dessault, by a cure attributed to mercury, gave that remedy great repute. It was given internally and by rubbing mercurial ointment on the sore and on the arm of that side. It is much used and relied on, but time rolled on and the use of mercury was found to be as inefficient as the other vaunted means.

It is very interesting to read of the heroic efforts which were used with every new medicine or physical means that were spoken of as being efficient to cure. Cold baths are much relied on, and patients were carried to rivers and not only dipped in, but kept in for long times, and held under, sometimes until almost drowned. Arsenic too, was extensively used as well as every quack remedy that had any repute. But all failed to hold the confidence of the physicians and the public.

And so from that time until the present, the treatment has been in the hands of non-professional people who have their vaunted remedies. The Fry's, Stoy's, Emery's and Vansciver's, and the mad-stone people have the confidence of the people, and physicians are ignored, as they deserve to be, in having confessed to an inability to cure a malady which they have never investigated as they should have done.

## IS THERE A PREVENTIVE OR CURE FOR THIS DISEASE?

The experience of two thousand years has proven beyond a doubt to every person who has studied the history of hydrophobia, that cleansing the wound thoroughly with caustic, or even incising it without caustic being afterwards applied, is a perfect preventive against rabies. No, not every person now. People who have institutes, like Pasteur in Paris, Gibier in New York, and C. N. Hewitt at Red Wing, to cure or rather prevent rabies in human beings, and who advertise the world over for persons to come to them, have seen that it is important to go back on their former, strong belief in the preventive means so long successful; so successful indeed that the great veterinary surgeon, Youatt, declared emphatically that the means spoken of, if done at any time previous to the actual development of the disease, would, if properly used, be successful in preventing further trouble. Yes, they not only declare these means not only useless, but ofttimes injurious. What motive inspires them? I need not say—a word to the wise is sufficient. Their acts speak as loud as their words. Despite their boasts Fry, Stoy, Emery and the mad-stone can all show greater success.

## ELECAMPANE AS A PREVENTIVE AND CURE.

Judge Richard Watson, after reading my pamphlet on hydrophobia, wrote to me as follows: "Are not many physical diseases brought about or greatly aggravated by mere mental fear or excitement? Your essay seems to point to this in hydrophobia. I remember hearing when a child that elecampane was a cure, or a preven-

tive of hydrophobia. My father had a favorite slut bitten by a rabid dog—he also bit some cattle that were said to have gone mad. The slut was kept chained for about a year and fed on elecampane and milk, then she was loosed and lived to die of old age. I thought it was an imprudent risk, but it showed their confidence in the medicine."

---

THE "OLD CHESTER VALLEY CURE" *

*From *Our Dumb Animals*, Boston, July, 1874.

A lady met me this morning, saying "Did you see that receipt in yesterday's paper for curing hydrophobia?" I had not seen it. "Well," she continued, "it is just the cure I wanted you to write about two or three years ago—the Old Chester Valley Cure."

I remember perfectly her anxiety that I should write to the public and proclaim that elecampane and fresh milk is the specific for hydrophobia, and my purpose is to repeat the account she gave me of it.

In her old home in Chester county, Pennsylvania, lived a German named Joseph Emery, who used to be sent for far and wide, when anyone had been bitten by a rabid animal. He went to see his patient carrying something understood to be a root, which he himself dug in the woods. He took a pint of fresh milk from the cow, put his root into it, boiled it, gave it to the patient fasting; made him fast after taking it: gave a second and third dose on alternate days and never failed in effecting a cure. In some way which she had forgotten, his secret transpired and the root was know to be elecampane. So well did he establish the local reputation of his specific, that, in his neighborhood, folks were not afraid of mad dogs.

The intelligence and integrity of my informant are beyond question, and I regret that her love of privacy should prevent her from giving the weight of her name to her conviction that this is an unfailing specific for hydrophobia. The people of Chester county are not a class likely to be misled by superstition, and she is confident that it was a general or universal belief that Joseph Emery never failed to cure or prevent hydrophobia. In one case the spasms had begun before the first dose was given, and the patient recovered. The medical properties of celeampane are very powerful. Milk itself is a specific for many poisons, and while the medical faculty know no cure for this terrible disease, we should open every avenue of light to the dark subject. If the disease is one of the imagination, we want a specific to give confidence and cure by the imagination; but this looks like a real cure of a veritable disease.—Jane Grey Swisshelm, in *Pittsbury Commercial.*

Robert Shoemaker, for a long time the experienced head of a wholesale drug house in Philadelphia, has been for about twenty years a strong believer in the protective power of elecampane as a preventive of rabies and has written much on the subject. I quote an article of his published in the *Philadelphia Ledger* years ago. "My attention was drawn to elecampane many years since as a preventive of hydrophobia. The active medical principle of the plant is found in the root and is called *inulin.* This I believe neutralizes the virus. Allow me to give a few instances, where this simple remedy has been used. My nephew, then a small boy, was badly bitten in the face by a dog unmistakably mad. The father of the lad came immediately to the city for advice. We called on an eminent physician, who at once prescribed the plant named. The root was given as hereinafter directed. No symptoms of hydrophobia appeared and the lad, now a hale, hearty farmer, lives to show the scar of the wound in his face." The physician above referred to, related to me a number of instances in which the remedy had been used and *always with success.* He, in fact, remarked, 'I never knew it to fail when properly administered.' I will give you but two cases:

"*First*, Two men living near the city were bitten by the same dog, and within fifteen minutes of each other. The dog was secured and the next day showed unmistakable signs of madness and finally died of hydrophobia. Alarmed for their safety, both men came to the city next day and waited on the physician quoted above. He prescribed elecampane root. One of the men remarked, 'that is an old woman's remedy' and refused to take it. The man returned home and put himself under the care of his own physician, who cauterized the wound and gave him medicine to salivate him. On the ninth day he was seized with spasms and died in

agony. The other man took the elecampane and never suffered in the least degree from the dreaded disease.

"*Second,* A number of cows in pasture were bitten by a mad dog. This coming to the knowledge of those who heard of the elecampane remedy, they thought it a good opportunity to give it a trial. The cows were accordingly separated. To one half the number, the root was administered (in form of decoction) and not one of the cows suffered from hydrophobia; whilst all of them not so treated took the disease and died from its effects, or were shot.

"In quite a number of cases coming under my observation of persons bitten by dogs supposed to be mad, I have recommended the use of the elecampane, and have yet to learn of the first case of hydrophobia resulting from such bite where the root was used. I have, therefore, good reason for confidence in the remedy. Whether after the disease manifests itself it would have a good effect, or any effect at all, I am unable to say. But the antidote is so simple and so readily obtained that it would be almost criminal not to employ it.

"Having said this much allow me to give the mode of using it. To one and one-half ounces of good, sound elecampane root, bruised in a mortar, add one pint of new milk, boil it to half a pint, strain off, and when cold take it at a dose, in the morning, fasting. No food should be taken for three to five hours afterwards. Repeat the dose on the third morning, allowing one morning to intervene, and again on the fifth morning. The above quantity is for an adult. For a child give a proportionate dose, say to one twelve years old, half the quantity."

The editor of the *Ledger* remarked on the above: "It is deemed proper here to express the strong belief that in a great many cases in which hydrophobia symptoms occur, the symptoms are induced by excited imagination and apprehension. Considering the large number of cases of injury from bites of dogs that occur every year and the small number of well authenticated cases reported as hydrophobia, persons who have the misfortune to get bitten may well afford to keep their minds at rest about the matter. Not less than a score of the carriers of the *Ledger* have been bitten by dogs, and some of them several times, but they, having no apprehensions of hydrophobia, have never developed the symptoms of that disease. It is well, nevertheless to have the elecampane ready at hand."

Such is the statement—scores of times these carriers were bitten, but having no dread of a disease from the bite of healthy dogs, they paid no heed to their injuries and yet no harm came to them. But despite the fact that millions of such cases have occurred and no harm resulted, we are now told by Pasteur, Gibier and Hewitt and other pupils of the Pasteur Institute, that there is danger of rabies from the bite of even healthy dogs, and all who are bitten should come to the Institute; travel at great expense, hundreds of miles, many of them, and leave a good fee, besides, with the Institute. Such shameless frightening of the public should call down on the heads of the trio, the scorn and censure of all *honest, sensible* people.

More testimony in favor of elecampane as a remedy. My long-time friend Wm. H. Johnson, ex-Superintendent of the Bucks County Public Schools, thus writes me: "Many years ago when a school-boy, a case occurred in Buckingham township. Samuel Gilbert had seven cattle bitten by a rabid dog. It was near my home. Samuel had heard of the use of elecampane; got it; had the root boiled in milk, and to six of the cattle the dose was given by drenching them. In the seventh the animal was so refractory, that after making a thorough trial, the attempt was abandoned *solely* on account of the difficulty. This one took the disease and died. The other six were never affected by it. This and other similar circumstances coming to the knowledge of my mother, she procured and cultivated it. I am very familiar with it and have great confidence in it. I would, though, as a means of greater security previously use the surgical remedies in conjunction with it."

A physician, a graduate of the University of Pennsylvania, well known to me, who in conjunction with his practice has a large drug store, recently wrote to me as follows, "I have for 36 years been furnishing a mad-dog doctor with one of the ingredients used by him. It is a confection of opium. He administers it in 3 gr. doses; equal to 1-10, or 1-8 gr. of opium. He uses it with chick-weed and I know not what else. The small doses

of opium are to allay nervous excitement and to make the patient comfortable."

In addition to the mad-dog doctors named already, there was in the early part of the nineteenth century a Dr. Van Sciver living at Somerville, New Jersey, who had a far-famed reputation for curing hydrophobia.

### POST-MORTEM APPERANCES IN THE RABID DOG.

These are of a distinctly negative character. There is an absence of specific changes. The membranes of the brain are generally injected to a variable extent. The longitudinal sinus is filled with dark colored blood. Heart and pericardium generally normal. The most important changes are a dark condition of the blood, some œdema of the brain and more or less catarrhal alterations of the mucous membrane, especially of the respiratory and digestive canals, and the striking emaciation of the whole animal. In cattle the morbid appearances are often similar to those of the cattle plague. In that disease, as we had it in this county a few years ago, they resembled those of pleuropneumonia. Now do those post-mortem appearances indicate that during life in man they could possibly produce the terrible sufferings spoken of as the invariably attendant on this disease? No! Far from it. Take away the mental anxiety; the disturbance of the nervous system induced by fear, and the suffering, judged of by the effect of such lesions in other diseases, would be that consequent on them in other cases.

## COMMUNICATIONS.

### EXHIBITION OF A CASE OF AKROMEGALY; WITH REMARKS ON TREATMENT BY DESICCATED THYROID GLAND.*

SOLOMON SOLIS-COHEN, M. D.,† PHILADELPHIA.

This case is brought before the Society in order to exhibit some structural changes not found, or at least not recorded, in every case of akromegaly, and to call attention to the apparently good results of treatment with desiccated thyroid gland.

As full details of the case will be published in the *International Clinics* (in my report of a lecture delivered some time ago to my Polyclinic class), I will be brief in the present instance.

The patient, who is some fifty-two or fifty-three years of age, applied to the Philadelphia Polyclinic about eighteen months ago for relief from an excruciating headache, which had for many months been so intense at times as to prevent his lying down, pressure on the scalp increasing the pain. Attention was at once attracted to the peculiarities of facial structures presented, and further examination demonstrated the characteristic curvature of the back and enlargement of the hands and feet. Photographs of the patient taken twenty years ago and six years ago respectively, bear out his statement that his features have materially altered within the last four years, although the later photogfaph shows the beginning of the change.

He has had to enlarge his hat-band twice, and his shoes twice within three years. The shoes are a little longer but much broader than formerly. The hands are broadened rather than lengthened; the fingers not exactly "sausage-shaped," but thick and clumsy. Distortion of the joints is to be attributed to his occupation, and probably antedates the development of the akromegalic conditions. Part of the coarseness of the skin of the hands may likewise be due to occupation. His hands to-day, however, are smaller than when he first came under treatment, as shown by our tracings and measurements, and also by his statement that a pair of gloves bought "some years" ago, and too small for him last year, can now be worn.

The enlargement and projection of the superciliary ridges, the lateral projection

*Read before the Philadelphia County Medical Society, April 11, 1894.

†Professor of Clinical Medicine and Therapeutics in the Philadelphia Polyclinic, Etc.

of the malar bones, the broadening and deepening of the chin, give the face the characteristic lengthened elliptical outline. The great enlargement of the nose; the thickening and projection of the lips; the heavy folds, deep furrows, and somewhat greasy texture of the skin, especially of the forehead; the stiffening and projection of the auricular cartilages, complete the picture. The lower jaw does not, however, project beyond the upper jaw. The teeth are bad. The tongue is thickened and deeply fissured. The voice is deep and has a monotonous quality, the latter only partly attributable to his "boilermaker's deafness." The laryngeal and tracheal cartilages are almost if not completely ossified. The thyroid gland cannot be demonstrated. The forward thrust of head and neck from curvature of the cervico-dorsal spine throws the clavicles well out from the windpipe, leaving a great hollow just above the sternum. The clavicles are enlarged, the scapulæ are enlarged, the ribs are broadened and apparently in contact, and the costal cartilages seem to be ossified. In consequence, although the narrowing of the chest—an apparent lateral compression—and the percussion phenomena show absence of emphysema, it will be observed that his breathing is scarcely at all thoracic. There is an almost inappreciable rise and fall of the clavicles, showing slight vertical motion of the thorax as a whole, and on great inspiratory and expiratory exertion an expansion of one-half to one centimetre can be determined at the nipple line. Breathing is almost exclusively abdominal. This shows, as did my previous case, and some cases of Dr. Dercum's and others, that the disease involves the bones of the thorax as well as those of the extremities.

Our patient is becoming feeble; his muscles are wasting, though as yet electric examination shows only quantitative change.

He has vasomotor phenomena—flushing, occasional vertigo, and polyuria. The urine has been deficient in solids, but has not contained sugar or albumen. We have not, indeed, demonstrated anything abnormal in it. This I attribute, however, to defective methods of examination. I have no doubt that careful chemical analyses will show in the urine the results of altered metabolism. Since treatment with thyroid-powder was instituted the quantity of urinary water has decreased and the urea-content has risen. Ordinarily the thyroid preparation increases both water and solids. Superficially the diminution of polyuria by a diuretic would seem to be an illustration of the so-called "homœopathic law." A moment's reflection, however, shows the action to be simply a correction of disordered metabolism, through which the production of toxins giving rise to polyuria is diminished. Another result of the administration of the thyroid-powder has been to completely relieve the distressing headache.

At one time, after a long absence from the clinic, he returned complaining of violent sciatic pain. It failed to yield to ordinary measures, but disappeared after recourse to thyroid medication. Five grains of the preparation of desiccated sheep's thyroid exhibited by me to the Society last year was given in capsule every morning.

Upon the somnolence, however, no effect has been obtained. The patient can still go to sleep upon the slightest provocation—indeed, without any. He falls asleep while waiting his turn at the dispensary, and frequently missed appointments through sleeping in his chair over the time set. He says that he can keep awake, however, while at work; but as he can no longer do the hard work to which he has been accustomed, he has not for some time had steady employment.

Dr. Jackson examined his eyes, and found no lesion of the fundus and no error in the visual field. This goes to confirm the view that hemiopia and other visual errors are merely secondary phenomena, due to pituitary enlargement, and that the latter is not necessarily a feature of the pathologic complexus. I am, indeed, inclined to believe that early treatment with thyroid preparations will entirely prevent overgrowth of the pituitary body, embryologic analogy seeming to indicate that it is an attempt at compensatory hypertropy, ill-directed and baneful only by reason of the altered position of the structure.

# ACUTE PUERPERAL CELLULITIS AND TRUE PELVIS ABSCESS.*

CHARLES P. NOBLE, M. D., PHILADELPHIA.

It is my purpose in this communication to report my experience with acute puerperal cellulitis and true pelvic abscess, collecting together in one paper the various cases which I have reported from time to time. The time has now come when such a communication will be received in a proper spirit—that is, as a report of conditions carefully observed at the bedside, and therefore as a contribution to scientific medicine. The first whirl of excitement which followed the discovery of the real nature of chronic pelvic inflammatory troubles has passed by. Men are no longer blinded by the prejudices of the era when all pelvic inflammation was regarded as cellulitis. A sufficient time has now elapsed to enable them to recover from the reactionary wave, during the height of which it was believed that all pelvic inflammation was necessarily tubal in origin. Practitioners of medicine are very prone to be ruled by the dogmas of a few leaders in professional thought, and gynæcologists are no exception to this rule. During two generations they gave implicit adherence to the dogma of Nonat, Churchill, and Emmet, and during the present generation no less implicit adherence to that of Tait and his disciples. It is now time to accept all the facts in the case whether or not they agree with prevailing theories.

CASE I.—This patient I saw operated upon May 8, 1888, by Dr. D. Longaker, who gave me the following history: Mrs. F., aged twenty-six years, III-para. She was delivered of the third child seven weeks ago, by a natural and easy labor. On the fifth day she had a chill, and chills and fever continued thereafter, also great pain. Dr. Longaker saw her seven weeks after labor, and operated for a clearly defined mass situated mostly in the left side of the pelvis, rising up above the brim of the pelvis and extending from the symphysis pubis to the iliac crest. An exploratory cœliotomy showed that both uterine appendages were of normal size, but were somewhat fixed by recent adhesions; "neither right nor left ovary nor tube formed any part of the mass; these structures could be distinctly outlined apart from it." Fluctuation was distinct in the swelling as made out by the intra-abdominal finger. A second incision was made above Poupart's ligament, and about half a pint of pus was discharged. The pus cavity was located in the left broad ligament, and extended between the uterus and bladder into the right broad ligament. The patient made a good recovery, but has borne no children since. This is probably because effectual means were taken thereafter to prevent conception.

CASE II.—This patient was seen at the Philadelphia Lying-in Charity during my service there as senior assistant physician. I am unable to find any published notes of the case. My recollection of its salient points is very clear and distinct. This patient was infected after labor, and after a number of days presented the usual evidences of suppuration, together with the signs of intense inflammation on the right side of the pelvis and in the right inguinal region. A hard mass of exudate formed in the right groin, which could be distinctly outlined by palpation. There was every evidence that this was a case of true pelvic abscess, but influenced by the teaching that all pelvic suppuration is intra-peritoneal, an abdominal section was made by Dr. Charles Meigs Wilson, assisted by myself. The uterine appendages were carefully examined, and it was evident that the pus accumulation was entirely distinct from them, and that it was external to the peritoneum. The abdominal incision was closed and the pus let out by an incision made above Poupart's ligament, near the anterior superior spine of the ilium. The patient made an uninterrupted and quick recovery.

CASE III.—This case I saw in consultation with Dr. Himmelwright, March 2, 1890. The history, as given to me by Dr. Himmelwrigt, is as follows: The patient had a miscarriage, January 3d, in the second month of pregnancy. One week later, symptoms of pelvic inflammation appeared, and a diagnosis of peritonitis was made. The patient got about by February 1st. After a week, pain was

* Read before Philadelphia County Medical Society, April 11, 1894.

felt in the right inguinal region, and gradually increased in intensity, extending to the lumbar region. After another week (February 15th) she was unable to walk erect and to put her foot firmly on the ground, but had to stoop forward. During this time the temperature remained normal and there were no chills. At times the pulse was slightly accelerated. The pain continued to increase, and, on February 27th, a swelling was noticed in the right lumbar region. March 1st, the temperature rose to 101° F., and the pulse to 120, and there were slight chills. March 2d, I saw her. The temperature was normal, the pulse about 90. The right inguinal region was tender, suggesting, indeed, appendicitis, but there were no symptoms to warrant the supposition. A semi-fluctuant swelling was found in the right lumbar region. The next day this swelling had increased, and a hard mass was felt in the right inguinal region, extending as high as the ribs. The swelling in the lumbar region was opened and two or three pints of pus escaped. Introducing my index finger, it passed around the ilium into the iliac fossa. A rubber drainage tube was introduced, and irrigated daily with a dilute solution of peroxide of hydrogen. This discharge gradually decreased and the tract rapidly healed, closing from the bottom.

It may be asked: "Why is this claimed as a case of true pelvic abscess?" The abscess was undoubtedly situated in the false pelvis on the right side. I had my finger in it. The entire absence of bowel symptoms excludes perityphlitis. The fact that, on examination, the uterus was found movable and the broad ligaments free from exudate—no fixation of the appendages—excludes pyosalpinx. Hence I take it, the abscess was due to the breaking down of an infected pelvic gland situated behind the peritoneum, in the right iliac region.

Case IV.—This case was in every way similar to the first. I saw the patient in consultation with Dr. Langrehr, five weeks after labor. The perineum had been torn, and was sutured some hours after labor. Septic infection occurred, and for three weeks the temperature ranged between 100° F. and 103° F. During this time there was no pain or distention of the abdomen, or tenderness of the uterine appendages on examination. The perineal wound became inflamed, however, and the stitches were removed. During the fourth week all the symptoms abated. At the beginning of the fifth week the fever increased and tenderness in the left inguinal region became marked. Purulent matter had been discharged *per vaginam*, but whether or not it came from the abscess which had formed was questionable. On examining the patient five weeks after labor, I found her much depressed, in a typhoid condition, with a swelling above the pubes and to the left. Under chloroform a mass of exudate was felt in the left broad ligament extending between the uterus and the bladder, and plainly palpable above the pubes. My diagnosis was true pelvic abscess. I advised median section for an absolute exclusion of complicating pyosalpinx; then a second incision parellel with Poupart's ligament, to evacuate the abscess. This was done by Dr. Langrehr on the following day. The uterus, ovaries, and tubes were found healthy. The omentum was, in places, densely adherent. The abscess was situated within the broad ligament, and extended upward behind and two inches above the ramus of the pubes. It contained about six ounces of thick pus, which was evacuated by an incision in the left inguinal region, directly above Poupart's ligament. The ultimate recovery was perfect.*

Case V.†—Mrs. G., aged thirty years, II-para, was delivered January 18, 1893, of a living child, after a normal labor. The placenta was delivered by the introduction of the hand. The following day Mrs. G. had a temperature of 104° F., and was suffering much from pain in the right groin and from tympany. On the night of the 20th, I saw her in consultation. The temperature was 103° F., the pulse 110, and there was marked tympany and much tenderness in the right groin. A striking feature in the case was that, although the bowels were very much distended, the abdominal wall itself was not very tense. The coils of distended bowels could be very plainly observed through the abdominal wall. The bowels had not been moved for four or five days. The patient was put upon quinine, strychnine, and digitalis, and the bowels were freely moved. Vaginal and intra-uterine douches

* The first four cases have been reported in the *Medical News* of August 29, 1891.

† Annals of Gynæcology and Pædiatry, June, 1893.

of corrosive sublimate were employed, although the lochial flow was not foul-smelling. The patient's condition remained very much the same until the seventh day, when the right broad ligament became infiltrated, so much so as to be plainly palpable above the brim of the pelvis in the right groin, while from below the anterior and right quarter of the pelvis was filled with exudate closely attached to the pelvic wall and displacing the cervix backward into the hollow of the sacrum. This exudate began to disappear about the fourteenth day, and was absorbed very rapidly. Convalescence was further interrupted by a nephritis, possibly of septic origin, and also by severe intestinal pain accompanied by diarrhœa, presumably due to inflammation of the large bowel. This patient was seen in consultation by Drs. Goodell and Parish. She eventually made a good recovery.

Case VI.—Mrs. H., aged twenty-eight years, II-para, was delivered of her second child in March, 1891, the labor being conducted by a midwife. She was infected and was extremely ill. I saw her with Dr. Leopold five weeks after the labor. At that time she was prostrated, with a rapid pulse, "leaky" skin, chills, irregular temperature—in fact, the classical symptoms of septic intoxication.

On examination the right broad ligament was found indurated and a mass of exudate extending on the right side of the abdomen almost as high as the umbilicus. From the extent of the *mass* it was supposed that a right pyosalpinx with an intraperitoneal abscess existed; but in view of the puerperal history and the existence of a cervical laceration the possibility of a true pelvic abscess was discussed. A median abdominal incision was made April 16th, and the abdominal viscera in the lower right quarter of the pelvis was found fused by adhesions. The patient took ether so badly, becoming cyanosed while still partly conscious, and the pulse was so weak, that I and the gentleman present were convinced that to attempt the separation of the adhesions, and the evacuation of the pus from above, would result in her death on the table from ether. An unsuccessful attempt was made to reach the pus by an incision made near the anterior superior spine of the ilium without giving more ether. The exploration was not pushed, owing to the patient's bad condition. The patient was then put to bed and improved for some days. Operation was again proposed and chloroform selected as the anæsthetic, which produced as much cyanosis as ether had done. An incision was now made directly over the broad ligament, the uterus was located, and the index finger was forced into the broad ligament, evacuating several ounces of pus. With rubber drainage a satisfactory convalescence followed.

October 27, 1892, I operated on Mrs. H. to cure a ventral hernia which had formed at the site of the third incision. On opening the abdomen I was surprised to find that the adhesions throughout the right side of the abdomen, which had been universal eighteen months before, had disappeared, except a point of adhesion between the omentum and hernial sac, and another between the omentum and broad ligament. Both appendages were perfectly healthy. This fact demonstrates what was believed when the pus was evacuated, namely, that it was not a pyosalpinx, but an abscess of the broad ligament.

The disappearance of the very extensive adhesions in this case is worthy of record as showing that peritoneal adhesions are not necessarily permanent.

It is of interest to report that during the summer of 1893 this patient was delivered of a living child after normal labor, and that she is at present in good health.*

Case VII.—Mrs. F., aged eighteen years, was confined May 8, 1893. She had a mild puerperal sepsis and was in bed for two weeks. The following month she was constantly sick, being in and out of bed, suffering with pelvic pain, anorexia, and having more or less fever. (The temperature and pulse I do not know, as I was not in attendance.) She came under my care six weeks after her confinement, and was admitted to the Kensington Hospital for Women. Examination showed a large inflammatory mass in the pelvis, absolutely anchored to the left pelvic wall. She was under observation for two weeks, with the temperature fluctuating between 99° and 102°F., with the general evidences of mild septic absorption, such as anorexia, sweats, chilly sensations, and increased pulse-rate.

* Reported in Annals of Gynæcology and Pædiatry, January, 1893.

Believing that pus was present in the pelvis, either in the form of a true pelvic abscess or a pyosalpinx, an abdominal section was made on June 26, 1893. The following conditions were found: The uterus was fairly well involuted and was displaced upward and backward by a mass in the left broad ligament. The right broad ligament and the right Fallopian tube and ovary were entirely normal, as was demonstrated not only by touch but by delivering the ovary and tube through the abdominal incision. The omentum was adherent to the anterior face and upper border of the left broad ligament in front of the Fallopian tube. This adhesion was separated. The left ovary and tube were found to be entirely normal; the meso-salpinx being normal, soft, and movable. This was demonstrated not only by touch, but by vision, the woman being in the Trendelenburg posture, so that the entire left side of the pelvis was in plain view. The left broad ligament was very much infiltrated with inflammatory material and firmly anchored to the anterior and left bony wall of the pelvis. Fluctuation was not apparent. It was determined to close the abdomen, and if septic symptoms persisted to open the broad ligament from below. That portion of the omentum which was adherent to the broad ligament was ligated and cut off. A small gauze drain was placed against the broad ligament where the omentum had been separated, so that should pus make its appearance at this point it would find its way out through the abdominal incision.

The patient's convalescence was uninterrupted; the temperature rapidly dropped to the normal, and her general condition steadily improved. The gauze drain was removed, good union of the abdominal incision was obtained, and the patient was discharged from the hospital at the end of four weeks. In the meantime, not only had her general condition very much improved, but the pelvic mass had almost disappeared.

This patient consulted me January 9, 1894, to ascertain the cause of a suppression of menstruation of three months. I found her to be between three and four months pregnant. A careful examination of the left broad ligament failed to discover any evidence of the former cellulitis, the left broad ligament feeling exactly like the right one.

The evidence of the existence of acute puerperal cellulitis as a primary condition in this case is absolute. There was not even a complicating pelvic peritonitis in the ordinary sense of that term, merely a point of adhesion between the omentum and the broad ligament, which was, of course, due to a small circumscribed area of peritonitis. I was able to demonstrate these conditions to a number of physicians who were present, including among others, Dr. Fullerton, of the Woman's Hospital.

What I wish especially to insist upon is that in this case neither Fallopian tube was involved in the inflammatory process, that both were entirely normal. The left Fallopian tube and its mesentery were scarcely even congested. The circumscribed area of peritonitis where the omentum was adherent to the broad ligament was plainly due to the fact that the inflammation had extended directly through the broad ligament to the peritoneum, leading to the adhesion of the omentum. That this is possible has been denied by those who maintain that all pelvic inflammation is due to infection which has spread through the Fallopian tubes. In this case the conditions present were unmistakable.

We thus have seven cases in all of which, except the third and fifth, an abdominal section was made, so that we have the evidence not only of the usual physical examination, but also that obtained from an intra-peritoneal examination. In Cases I., II. IV., and VII., the abdomen was opened and the uterine appendages were examined, and it was demonstrated that they were either free from disease, or at the most, lightly attached by recent adhesions. In these four cases there is not a shadow of a doubt that the disease was in the broad ligament, and that it spread to the ligament directly from the uterus or vagina by way of the lymphatics.

Case VI. was undoubtedly not a case of pyosalpinx, and I have no question myself that the pus was located in the broad ligament. A carping critic might affirm, that even although it was not a pus tube, that the pus was intra and not extra-peritoneal, and that it was due to suppurative peritonitis. My opinion that the pus was in the broad ligament is based upon the fact that the pelvic exudate was anchored to the anterior and right pelvic walls, and that when I cut down upon the

mass I recognized the uterus and tore through the broad ligament with my finger in front of the Fallopian tube.

The evidence in Cases III. and V. is not so absolute as in the others, and they are included in this list not for the sake of *demonstrating* the occurrence of puerperal cellulitis, as is done by the other cases, but because of their relative bearing upon the subject.

The foregoing cases demonstrate several interesting facts with reference to obstetrics and gynæcology:

1. That in the puerperal state, pelvic cellulitis and true pelvic abscess occur as the result of septic inflammation.
2. That inflammation may spread from the vagina or uterus along the pelvic lymphatics to the broad ligaments without involving the Fallopian tubes.
3. That peritonitis can be set up by the spread of inflammation from the broad ligaments to the peritoneum without involvement of the Fallopian tubes.
4. That very extensive pelvic exudate and intra-peritoneal adhesions can be absorbed.

It hardly seems worth while to bring evidence to bear in support of our first proposition, and it would not be called for were it not that a few men of wide experience maintain the contrary. Being able to present absolute evidence in the shape of carefully and thoroughly observed cases occurring in my own practice, I shall not take the time or trouble to make reference to the literature.

What I have said concerning proposition one is equally true of proposition two, which is distinctly proven by certain of the foregoing cases. Case VII. is a beautiful illustration of the fact that a very extensive puerperal cellulitis can be present and yet the Fallopian tubes be entirely healthy. In this case they were scarcely, if at all, congested, and the meso-salpinx was entirely free from infiltration.

The third proposition is likewise proven, especially by Cases IV. and VII. In both of these cases the omentum was adherent to the broad ligament, although the tubes were free from disease. I have no doubt that pelvic peritonitis is usually due to the spread of inflammation from the endometrium through the Fallopian tubes to the peritoneum, but these cases show that this rule is not without exceptions. Numerous other exceptions have come under my observation. For instance, a short time ago I did a hysterectomy for a fibroid tumor, in which the tumor, being impacted in the pelvis, was adherent to the rectum and posterior pelvic wall, over an area of at least nine square inches, and yet in that case the Fallopian tubes were entirely normal. In several cases of appendicitis I have found the peritonitis to extend to the pelvis, the Fallopian tubes having nothing to do with its occurrence. Moreover, it is a well-known fact, that when small tumors, especially dermoids, become wedged in the pelvis, or become twisted upon their pedicles, that peritonitis ensues. Likewise, that in cases of malignant disease of the abdominal or pelvic organs, adhesions are almost always present. Therefore, it must be admitted that pelvic peritonitis can occur independent of salpingitis.

Case VI. demonstrates our fourth proposition. In that case the entire right lower quarter of the abdomen was fused together by recent peritoneal exudate, and light adhesions had formed in the left half of the pelvis, yet eighteen months later, when the abdomen was reopened, the entire mass of adhesions had been absorbed, with the exception of a small point between the omentum and right broad ligament, and another small point between the omentum and the hernial sac. Owing to the very extensive character of the adhesions in this case, it is a striking example of the fact that recent adhesions can be entirely absorbed.

Two women of the seven whose cases have been detailed in this report have been delivered of living children since their recovery from the attack of acute puerperal pelvic cellulitis.* The subsequent history of four of the other five women is unknown to me. The fact that two of these women have borne children is of interest because of its bearing upon the question of the relation of pelvic exudates to sterility. As this paper has dealt only with demonstrated facts, I shall merely suggest that the occurrence of pregnancy after the existence of extensive exudates, forming during the puerperal state, is best explained in many cases by the fact that the condition present is a puerperal cellulitis rather than a diseased tube. It is a severe tax upon my credulity to accept the state-

* Since writing this article I have learned that Dr. Himmelwright's patient (Case III.) has been delivered of a living child, after a normal labor.

ment that extensively diseased tubes, more especially pus tubes, can so far recover as to permit the occurrence of pregnancy; and I believe that the true explanation in not a few cases of pregnancy following the recovery from puerperal pelvic inflammation is, that the disease was originally in the broad ligament and not in the Fallopian tube.

In conclusion, I wish to say a few words concerning the relative frequency of acute puerperal cellulitis and inflammation of the Fallopian tubes. I believe as firmly as any one, that pelvic cellulitis and true pelvic abscess are comparatively rare conditions, and that the usual variety of pelvic inflammation is a salpingo-peritonitis. I have not met with pelvic cellulitis except in the puerperal state, and have no reason to believe that it occurs in the non-puerperal state, except as a result of infected wounds of the vagina and perineum. As such conditionsare very infrequent, a pelvic cellulitis in the non-puerperal state would be a surgical curiosity.

I have added these remarks lest it might be inferred by the unthinking that I am desirious of supporting the old and abandoned theory of Nonat and Emmet concerning pelvic inflammation. At the same time I am glad to be able to present incontestable proofs of the occasional occurrence of acute puerperal pelvic cellulitis and true pelvic abscess.

# TRANSLATIONS.

## THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

### CHLOROSIS WITH MENORRHAGIA.

Dr. Ch. Liegeois (*La Semaine Médicale*, No. 22, 1894) prescribes in chlorosis with associated menorrhagia, the following pill, with advantage:

| | | |
|---|---|---|
| ℞ | Protochloride, or Sulphate Iron..2 | 50 (grs. xxxviij). |
| | Extract Hyoscyamus.....1 | 0 (grs. xv). |
| | Alcohol. resinous Ex. Hydrastis..5 | 00 (ʒj ¼). |
| | Licorice Powder.....5 | 0 (ʒj ¼). |

Sufficient for one hundred pills—gelatine coated. Two pills at each meal during the menses and the intervals as well.

### TREATMENT OF SYPHILIS.

Prof. Lang (*Gazzetta Degli Ospitali*, No. 26, 1894) though an advocate of the internal treatment of syphilis, recognizes the disadvantages of this method: the difficulty of exact dosage and the dangers of mercurial poisoning. To remedy these inconveniences he employs the following formulæ:

| | | |
|---|---|---|
| ℞ | Protoiodide Mercury.....1 | 50 (grs. xxij). |
| | Extr. Opium..... | 50 (grs. vijss). |
| | Lanoline.....1 | 50 (grs. xxij). |
| | Sugar Milk..... .4 | 50 (ʒj ½). |

Sufficient for fifty pills. One to two per diem.

| | | |
|---|---|---|
| ℞ | Calomel.....2 | 50 (grs. xxxvij). |
| | Extr. Opium..... .... | 25 (grs. iv). |
| | Lanoline .....1 | 50 (grs. xxij). |
| | Sugar Milk.....3 | 75 (grs. lv) |

Sufficient for fifty pills. One to two a day.

| | | |
|---|---|---|
| ℞ | Corrosive Sublimate..... | 25 (grs. iijss). |
| | Extr. Opium..... ..... | 50 (grs. vijss). |
| | Lanoline.....1 | 50 (grs. xxij). |
| | Sugar Milk .....3 | 75 (grs. lv). |

Sufficient for fifty pills. One to two per diem.

If necessary, he also associates the use of arsenic or the iodide of potash, with these formulæ; also in pill-form, according to the following formulæ:

| | | |
|---|---|---|
| ℞ | Iodide Potash.....10 | 0 (ʒijss). |
| | Sugar Milk..... 5 | 0 (ʒj¼). |
| | Lanoline..... 3 | 0 (grs. xlv). |

Sufficient for fifty pills. Three, ten, or fifteen a day.

| | | |
|---|---|---|
| ℞ | Arsenious Acid..... | 50 (grs vijss). |
| | Sugar Milk. .....6 | 50 (ʒj ¼). |
| | Lanoline.....3 | 00 (grs. xlv). |

Sufficient for one hundred pills.

The addition of lanoline, which melts at the temperature of the interior of the body, and the sugar of milk which easily dissolves in the gastro-intestinal juices, provide that no particles of these drugs pass through the digestive tract unaltered, so that one may be certain that the quantity of the drug ingested will be absorbed. Thus exactness of dosage and prevention of poisoning are assured. If one will employ a hypodermatic preparation he warmly recommends, from a long experience, the following:

| | | |
|---|---|---|
| ℞ | Mercury..... | |
| | Lanoline, ana.....4 | 0 (ʒj). |
| | Olive Oil.....6 | 0 (ʒjss). |

Inject five ccms. under the skin of the back every three to four days at the beginning, every five to eight days when the symptoms retrogress progressively, and every eight to fourteen days—not more than twice—when they have completely disappeared. He avoids injections into

*In charge of the Translator, F. H. Pritchard, A. M., M. D.

the nates for fear of wounding veins, producing pulmonary embolism, suppuration, etc. The injection into the skin of the back is made four centimetres to the left of the spinal column where they may be continued in the same vertical line four cms. from each other; thus on one side one may inject from five to six times. The other injections may be given on the opposite side. A radical treatment requires from eight to twelve such injections; recurring forms from four to eight. If more than twelve are necessary then make them in a vertical line, eight cms. from the median line.

---

TREATMENT OF RENAL LITHIASIS.

In *L'Union Médicale*, No. 37, 1894, the following treatment of renal lithiasis is recommended:

Quiet the pain with one or two injections of morphine. Put the patient into a warm bath for an hour or an hour and a half; repeat this during the day if necessary. In children over five years, the same treatment as adults; if less than five years, warm baths, very hot poultices to the abdomen, or if not relieved a chloroform stupe. If the pain is intolerable, ether or chloroform inhaled to slight anæsthesia. If the stomach is tolerant, a little morphine and belladonna. Cold rectal injections.

SUBACUTE CRISES.—A rigid diet, the benzoate of lithine. At each meal gms. .50 (grs. vijss) of salol. Milk is an excellent article of diet, white meats, spinach, lettuce, much fruit. Eat but little and masticate well. On arising drink a glass of pure water. The patient should drink enough, either during meals or in the intervals, to be able to pass a quart and a half of urine in a day. Avoid constipation. If bowels are irregular, take from a teaspoonful to a tablespoonful of the tartrate of potash and soda in a glass of the liquor from macerated licorice roots. Evacuate the bladder frequently. Exercise which is most agreeable to the patient. When once sweating, have him change his linen and rub himself dry. Avoid taking cold above all things. Alkaline baths once or twice a week.

DRUGS.—Two principal indications: alkaline medication and diuretics.

*Alkalies.*—The benzoate of lithia, one to two grams (grs. xv-xxx) a day, in two doses, an hour before dinner and supper. Continue these for ten days of each month, and the remaining twenty days the diuretic treatment. The bicarbonate of soda is much used:

℞

| | | |
|---|---|---|
| Bicarbonate Soda | 2 | o (grs. xxx). |
| Powdered Tartaric Acid | 1 | o (grs. xv). |
| Calcined Magnesia | | 75 (grs. xij). |

Sufficient for one powder. One an hour before each dinner and supper. A glass of milk after the powder.

*Oxalic Deposits.*—Avoid foods rich in oxalic acid: gooseberries, tomatoes, pieplant, milk, waters surcharged with gases, and cheese. Order meats, fish; the phosphate of soda, one gram (grs. xv) after each meal and on going to bed. Diuretics. It may be observed that in children which eat too much of soups and boiled dishes to replace them by eggs and milk.

---

TREATMENT OF PSORIASIS.

Dr. Coffin (*Le Sperimentale*, No. 6, 1894) states that treatment will vary according to the form of the disease.

In cases of moderate severity he removes the scales with alkaline baths, soaps, etc. Then he employs the following:

℞

| | | |
|---|---|---|
| Glycerolate of Starch | | |
| Oil Juniper, ana | 100 | o (℥iijss). |
| Green Soap | 5 | o (℥j ¼). |
| Salicylic Acid | 3 | o (grs. xlv). |

Every three or four days the affected spots are washed with warm water and tar soap. Pyrogallic acid or chrysarobin may be used instead.

In diffuse forms with pronounced inflammatory symptoms he employs, with advantage, prolonged baths—for five to six hours—and applications of mild salves.

In cases with limited eruptions he employs Vigo's plaster.

In obstinate cases he removes the scales and applies the following salve:

℞

| | | |
|---|---|---|
| Ichthyol | | |
| Salicylic Acid | | |
| Pyrogallic Acid | ää.. 2 | o (grs. xxx). |
| Vaseline | | |
| Lard | | |
| Lanoline | ää..30 | o (℥j). |

The patient should be well nourished and avoid coffee, alcohol, tea, etc. Arsenic is only indicated when the disease has ceased to progress.

---

A woman can walk and a woman can talk,
And fritter away a whole day;
But with all of her folly she can't jump a trolley,
Because she ain't built that way.

# THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address care P. O. Box 843, Philadelphia, Pa.

HAROLD H. KYNETT, A. M., M. D.
Editor

RODERIC C. PENFIELD
Publisher

147-149-151 North Tenth Street, Philadelphia

**TERMS:**—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

**REMITTANCES** should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

**NOTICE TO CONTRIBUTORS:**—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 26, 1894.

## EDITORIAL.

### A CORDIAL INVITATION.

Two years ago the American Medical Association met in Detroit, last year the meeting place was Milwaukee, and this year the Association will enjoy the hospitalities of the profession of the Pacific coast, during its session in San Francisco. Since for three consecutive years the meetings have been held in Western cities, it would seem to be in the natural order of things for the meeting of 1895 to be held in some Eastern locality.

In anticipation of this probability the REPORTER has called the attention of the citizens of Asbury Park, N. J., to the desirability of securing the meeting of the American Medical Association for 1895, for that city. A year ago, at the suggestion of the REPORTER, Asbury Park extended a similar invitation to the Association, but for sufficient reason an invitation from San Francisco was accepted. The invitation to become the guests of Asbury Park will again be extended to the Association, and there are many reasons why it should receive the most favorable consideration.

Very briefly stated, we may say that Asbury Park is located on the northern coast of New Jersey, about midway between New York and Philadelphia, and within easy communication of these two cities, the greatest medical centres of of America. It is essentially a health and pleasure resort. It is the greatest, cleanest, healthiest; the most attractive, most desirable and most popular of all the health and pleasure resorts on the Atlantic coast. Its facilities for the entertainment of large numbers of visitors are superior; its numerous hotels being fully equipped with all modern conveniences, enable it to handle with ease the influx of three score thousand or more visitors, who from year to year make it their summer home.

The desirability of the place for the meeting of large bodies of men is sufficiently indicated by the fact that during the coming summer there will be held at Asbury Park, the annual meeting of the National Editorial Association, and, in the height of the season, the many thousands attendant upon the meetings of the National Educational Association will be the guests of the city. Other conventions

also will be assembled there during the coming summer.

Among the conveniences of Asbury Park may be mentioned its electric street railways, its water supply from artesian wells, its lighting by electricity and gas, a system of sewerage which is conceded by sanitary experts a model system, and a Board of Health, whose conception of duty is to actively search out "nuisances" of any character and promptly eliminate the same, instead of carefully concealing them.

Of the physical attractions of the place it is not necessary to speak here, save to mention its famous plaza, the greatest and most popular promenade in the new world.

Another point deserving full consideration is the fact that the invitation to the American Medical Association is extended directly by the city authorities, whose assurances are not problematical, and who assume all responsibility for carrying out the details as outlined in the invitation. As a result, this will relieve the local profession of many perplexing conditions, secure concessions which it would be impossible for any body of medical men to obtain from authorities who were but slightly interested, if not utterly indifferent to the possible benefits of such a meeting within their territories.

In the one item of transportation the concessions given at the instance of the municipal authorities may prove a greater saving to the Association than the sum of all concessions otherwise made to its own officials. And where, as in the case of Asbury Park, all business interests combine in extending the invitation, the aggregate of the concessions made will be of great economic value to the Association.

When the REPORTER offered the suggestion, it claimed no authority in the premises and held out no inducements. The citizens of Asbury Park accepted the suggestion and acted upon their own responsibility.

They already have the greatest summer resort for health and pleasure on the Atlantic coast. They are determined to make it the greatest all-year-round resort in America. To this end they invite the the closest personal scrutiny of their conditions, natural and acquired.

Neglecting no other means of informing the public, they seek to substantiate their claims by affording to all opportunity of proving them by individual experience and observation. Hence they offer the most generous hospitality and entertainment of representative bodies of all kinds, —a policy the wisdom of which has been fully demonstrated in the past.

## About Mushrooms.

"*A Guide to the Study of Esculent and Poisonous Fungi*," *by Julius A. Palmer, Jr. Lee & Shepard, Publishers, Boston, Mass. $2.00.*

The work is a painstaking effort to point out accurately the difference between esculent and poisonous fungi, and to a great degree must be considered by the medical profession as a valuable text-book. The author upsets the popular theory, among laymen at least, that the changing in color of some fungi indicates their poisonous nature.

"Nothing could be more false. There is one, *Boletus cyanesceus*, which turns throughout the most beautiful blue, many that assume this color in lighter shades, and one that turns blood red: this change showing itself wherever the substance is bruised or cut. These are all esculent, while the dangerous Amanita remains the purest white under all conditions; that eatable mushroom, the nearest resembling the Amanita, may be distinguished by the fact that its gills turn pink or reddish the moment it feels the fire."

Copious extracts from previously published articles are given with the author's comments thereon.

As long as our people persist in the habit of gathering mushrooms(?) basing their ability to distinguish the difference between eatable and poisonous varieties on their knowledge of the characteristic of two or three sorts, just so long will we be in need of authoritative text-books (of which we now have too few) on the effects of each poisonous variety and the proper treatment of the patient.

# ABSTRACTS.

## NATURE OF PERITONITIS.

At a meeting of the Medical Society of London, the author, Mr. Treves, (*Lancet*, 1894) delivered the first Lettsomian Lecture on the Nature of Peritonitis, which is as follows:

I have ventured to select peritonitis as the subject of these lectures, not only on account of the fact that the diseased conditions known by that name still occupy a terrible prominence among the causes of death, but because the present time appears to be peculiarly convenient for reviewing the clinical and pathological aspects of this fatal trouble, and for criticising opinions which the custom of years has endued with a spurious appearance of accuracy. By peritonitis is understood an inflammation of the peritoneum. From the limited standpoint of morbid anatomy no exception can be taken to this definition; but when it is assumed that the various clinical phenomena which are classed together under the title of peritonitis are due either solely or in the main to an inflammation of the great serous membrane, then the definition becomes to some extent misleading, for peritonitis, clinically as well as pathologically, has comparatively little to do with inflammation of the peritoneum, and it would be erroneous to state that the majority of those who die of what is called peritonitis die of a peritoneal inflammation. Inflammation is by many still referred to as a calamity, as a thing that is violent, as an utter evil, and as an ill wind that can blow no other than ill, and the measures to be directed against it are commonly considered to be as drastic as those necessary to arrest the progress of fire and pestilence. This view of the inflammatory process needs to be amended, for it is by this process alone that the poison in an inoculated wound is destroyed and the growth of a parasite is arrested. But for inflammation, a man who is accidentally inoculated with a septic micro-organism becomes at once little more than a test-tube prepared for the favorable development and culture of the particular coccus or bacterium; he may be regarded as an organism not far raised above the level of a peculiarly-shaped mass of agar-agar. In a case of tuberculous phthisis it is not the inflammation which is to blame as the cause of death, but the bacillus which has produced it; the inflammation of the lung prolongs the infected man's life, and his prospects of improvement and recovery depend almost wholly upon it. The "white swelling" of a tuberculous arthritis illustrates the often successful attempt of the organism to rid itself of the tubercle bacillus by means of the inflammatory process, the latter being not a malignant energy working for evil, but a process the object of which is protective, and its end is shown by the freeing of the body from noxious organisms which lead to death. Yet the process may be excessive in individual cases, may be attended by certain disasters, and may fail to some degree in its purpose. It may be assisted and modified by treatment where the latter is directed towards removing the irritants from the tissues. And what has been said of inflammation in general applies equally to inflammation within the great serous cavity of the abdomen; it is an attempt on the part of the organism to avert a too potent cause of death.

The relation of what is clinically known as peritonitis to the inflammatory process requires careful consideration. In the larger number of fatal cases the leading symptoms are those of toxæmia. So far as the clinical aspect of a patient dying from peritonitis goes, he might be dying from snake-bite or from cholera poison, and after death the amount of inflammation discovered is out of all proportion to the phenomena which preceded death. A little injection of the peritoneum, with loss of its polished surface, a little general stickiness with a few frail adhesions, and a scanty mixture of pus and turbid fluid, are often all that is found. This is not the formidable kind of effusion which would be expected in a case of death from inflammation. The larger the dose of poison the quicker is the fatal result and the fewer are the manifestations of peritonitis; this is true both of human beings and animals. Death in the acute cases is said to have resulted from shock caused, in the majority, by profound nerve irritation from the sudden spreading of noxious micro-organisms or their products, over a

wide and sensitive surface. After a smaller dose life lasts for three or four days with symptoms of acute peritonitis, and yet after death the serous membrane shows but the early manifestations of inflammation. In other instances recovery follows after a more or less desperate illness, and this may be effected with or without the development of encysted suppuration. Of course the power of resistance of the individual must be considered as well as the dose of the poison. The favorable cases of peritonitis are usually those in which suppuration is most pronounced, whilst the most acute and unfavorable cases show the least inflammatory changes.

The surgical treatment of acute diffused peritonitis as a purely inflammatory affection by incision and evacuation of the effusion has been comparatively unsuccessful. The mortality attending the operation for strangulated hernia has not greatly improved since the introduction of aseptic measures in surgery, and in cases in which neither gangrene nor perforation of gut occurs, there is something besides mere inflammation which leads to death.

All this is evidence that in the larger proportion of examples of fatal peritonitis the leading symptoms are those of poisoning and not of inflammation; but it must not, on the contrary, be assumed that inflammatory phenomena are wholly subordinate in peritonitis, for in pelvic troubles and in appendix cases the signs of inflammation are paramount. It is obvious that the peritoneum has peculiarities and that there are phenomena attending its lesions which a reference to like disturbances in other serous membranes cannot explain. Suppurations of the pleura have not the same gravity, and this is not explained by the different extent of surface in the two cavities or by a resulting disturbance of function in the viscera covered by the respective membranes. So far as the function of viscera is concerned the visceral disorders in many cases of severe lead poisoning which end in recovery, are more considerable than they are in some examples of peritonitis which end fatally in a few days.

The following points may be noted with regard to the peritoneum:

1. Its surface is probably as great as that represented by the whole integument of the body.

2. It can absorb an amount equal to from three to eight per cent. of the body weight.

3. It offers a limited resistance to septic organisms and their products, the resistance varying within wide limits and being affected by age and disease.

4. No tissue in the body provides more favorable conditions for healing.

5. It does not show the same degree of vulnerability in all parts, nor are all portions of it alike in the manner in which certain lesions are responded to. The part covering the small intestine is most susceptible; the parietal layer is least so. Localized forms of peritonitis and encysted exudations are comparatively uncommon in the large area occupied by the small intestine and are commoner in the subphrenic region, between the dome of the diaphragm above and the transverse colon below, to the outer side of the cæcum and in the pelvis. Extensive inflammation may occur in the hepatic and pelvic regions without inducing very alarming symptoms. Injuries of the intestine are usually fatal, while lesions of the liver and bile passages are commonly slow and moderate.

6. The peritoneum appears to be possessed of great sensitiveness, peculiar and not quite comparable to that possessed by the skin; this is a matter of moment in the production of shock. The sensibility is dulled or lost when the surface is inflamed or covered with lymph.

7. A matter of great interest, though of some obscurity, concerns the condition of pressure within the abdominal area, and the effects which follow the disturbance of it. The cavity of the peritoneum is, of course, a potential space, and the creation of an actual cavity after incision will produce a disturbance of pressure relations which cannot be without effect on the sensitive tissues, and thin-walled blood vessels within the abdominal parietes.

The effect of a mere incision into the abdomen is often very remarkable. To the surprise of the operator, a simple incision into the abdomen in a case of tuberculous peritonitis, followed by evacuation of the fluid, has been succeeded by complete cure, and numerous instances are on record in which simple incision has entirely relieved abdominal trouble; in many of these neurosis as a causative factor of the trouble seems to be out of the question. There are certain other points in connec-

tion with intra-peritoneal pressure which remain to be mentioned. In the first place gravity does not appear to follow the usual lines within the abdomen. In the second place the frequency with which the escapes of fæces fails to take place in spontaneous perforation of the intestines, and in punctured wounds of that viscus is somewhat remarkable. Both Travers and Ziegler account for this by the state of intra-abdominal pressure, and Klemm asserts that the idea of the wound in the bowel being blocked up by prolapsed mucous membrane is fallacious.

8. The last point concerns the possibility of the peritoneum acquiring some degree of immunity from septic infection. This condition of immunity can be produced artificially in animals and appears to be possible in the human subject. Other things being equal, an operation carried out within the abdomen of a person who has had chronic peritonitis or who has exhibited repeated sub-acute attacks, and whose peritoneum presents substantial adhesions, is likely to be attended with better results than when the peritoneum is found to be wholly undisturbed.

In advanced cases of appendix trouble the disproportion which is often noted between the constitutional disturbance and the local condition discovered at the operation, appears to be capable only of the same explanation. In looking over the records of laparotomy performed for perforations in the stomach or bowel, it is impossible not to be struck with the fact that in many of the successful cases, there had been long antecedent visceral or peritoneal trouble.

## TREATMENT OF EPILEPSY.

Prof. Lemoine (*Revue Generale de Clin. et Therap.*; Cincinnati *Lancet Clinic*) recommends, in the management of epilepsy, an extensive surveillance, of which the most important points are as follows: The mental diet of the patient should be carefully watched, that he be kept free from all physical and mental exhaustion, psychic excitement, sudden alterations of the temperature, and disturbances of digestion. Alcoholic drinks and coffee are to be forbidden, and constipation to be treated. In the treatment of the attack itself, he recommends a rectal injection containing two grammes (30 grains) of the bromide of potash and chloral, to be administered in the intervals between attacks. If it fail to act after four hours, then give a second one, and even a third, after eight hours. During the attack the patient should be laid either on the floor or a bed and the garments loosened around his throat. In case the seizures rapidly re-occur (he has seen 220 within twenty-four hours), the patient should be placed in a dimly-lit room, and, after cessation of the attacks, it is best to have the patient rest in bed for one day, with substantial but not bulky diet. In traumatic epilepsy he recommends operative interference, while, if it depend upon syphilis, the iodide of potash and mercury are the best means of treatment. For three weeks inunctions of six grammes (1½ drachms) of mercurial ointment are rubbed in daily, and then the iodide in rapidly increasing doses, from two to eight or ten grammes per diem. After cessation of the attacks the inunctions and the potash salt are continued from one to three months longer and the latter for a year, after each meal. By the use of a great deal of milk the tolerance for these remedies is increased. In menstrual epilepsy he administers every three days ten grains of antipyrine and four grains of the bicarbonate of soda, and as soon as the arterial tension is affected he adds a grain of the powdered leaves of digitalis. If there are, simultaneously, pains in the hypogastric region, he has an enema containing ten drops of the tincture of opium given. In the employment of the bromides the addition of hyoscyamine is of great service. He advises the following combination:

℞

| | |
|---|---|
| Bromide of potash | gms. 30 |
| Bromide of sodium | |
| Bromide of ammonium | āā gms. 15. |
| Hyoscyamine | mgms. 15 |
| Water | qt 1 |

If signs of bromism appear he substitutes the bromide of gold for the other bromides, dissolving three grains in sixteen ounces of water. Of this mixture one or two teaspoonfuls per diem may be given. The bromides he always prescribes in watery solutions, and never in syrup. The doses should be large. Borax may be given with advantage in a daily dose of two or three grammes (30 to 45 grains).

## THE AMERICAN MEDICAL ASSOCIATION MEETING.

The American Medical Association will meet in San Francisco, June 5th to 8th, inclusive.

The entire work of the Association will be done in Odd Fellows' Building, cor. Market and Seventh streets.

Exhibition room for instruments, pharmaceutical preparations, etc., is also in this building.

Registration will begin in Marble Hall, Palace Hotel, on Monday, June 4th, when all who arrive early enough should register to avoid the rush on Tuesday. Working hours of the Sections will be 9 to 12 and 2 to 5—except forenoon of the first day.

The general assembly will convene at 10 o'clock on Tuesday.

The following hotels have quoted special rates for members and their families: Palace, Grand, Lick, Russ, Occidental, California, Baldwin and Pleasanton.

There will be room for all. Visitors desiring to engage rooms in advance can do so by communicating directly with the hotels, or with R. A. McLean, No. 305 Kearny street, Chairman Committee on Hotels.

Headquarters at Palace Hotel, where there will be a concert in the Grand Court, Monday evening, June 4th.

Tuesday evening a reception will be held at Pioneer Hall, Wednesday evening at Cooper Medical College, Thursday evening at the Midwinter Fair, and Friday evening at the Hopkins Art Institute. The Ladies' Committee on Reception—Headquarters Palace Hotel—will provide entertainment for visiting ladies during the day.

Saturday will be devoted to an excursion around the Bay, starting at 9 o'clock and returning at 5, passing in view of the Irving Scott Ship-building Yards, Spreckles' Sugar Refinery, U. S. Military Posts-Alcatray, Fort Mason, Presidio, Fort Winfield Scott, and out to the "*heads*" for a touch of old ocean; returning, pass U. S. Quarantine Station and land at Mare Island, where an hour will be spent inspecting the Goverment Hospital and reconstruction works.

Railroad tickets will be good for return till July 15th, members will therefore have time to make numerous side excursions in the State, after the meeting. On the S. F. & N. P. Railway, the rate for such excursions will be a single fare for a round trip.

The S. P. Co.'s rate will be one and a fifth to one and a third fares for a round trip. Some of our seaside and mountain resorts, Mineral Springs and Sanitariums will well repay for time spent on a visit. Among them are Santa Cruz, Del Monte, Santa Barbara, Santa Monica and Coronado; peerless Yosemite and her giant Sequora forests, Lake Tahoe and Mount Shasta; Paso Robles, Arrowhead, Gilroy Mt., Byron, Soda, Vichy, Geysers, Harbin, Bartlett, and Highland Springs, all possessing medicinal virtues, and justly popular with our own people.

Special inducements are offered at all these places; Paso Robles Hotel offers the best entertainment for members at half regular rates, and Highland Springs, in the "Switzerland of America," with its latch string on the outside, invites members to come and partake of its hospitality, free as the bubbling waters of its springs.

June will be the height of the season for the Alaska excursion, unequaled by any other trip in the world save that to North Cape.

Members who desire to secure accommodations in advance for this trip can do so by applying to the Committee of Arrangements.

Any one desiring to secure space in Exhibition Hall should apply to R. L. Ridgon, Nucleus Building, Chairman Committee on Exhibits.

If members who are getting up excursions will immediately send us approximately the number we may expect from their respective localities, it will simplify our work of preparation for reception and entertainment.

We request also that they will wire us the exact number on departure of their trains.

R. H. PLUMMER,
Chairman.

---

THE teacher was trying to teach Jones the alphabet. She pointed to the letter X.

"What's that letter?"

Jones (bashfully)—"Guess don't know, marm."

Teacher—"O, yes. Think a minute."

Jones (brightening) —"Yes, marm. Dat's daddy's name.—*Boston Globe.*

# SOCIETY REPORTS.

## THE SURGICAL SECTION OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

*Meeting of April 13, 1894.*

[Stenographically Reported by C. C. Mapes, M. D.]

### RADICAL OPERATION FOR CONGENITAL HYDROCELE IN AN ADULT.

Dr. Thomas S. K. Morton presented a man, aged twenty years, upon whom he had operated six weeks previously for congenital hydrocele of the tunica vaginalis testis. Incision and ligature of the neck of the sac, with subsequent packing with iodoform gauze, was the method of treatment adopted.

The symptoms were: large fluid distention of the right tunica vaginalis; pain and sense of weight; disappearance of the fluid over night and upon prolonged pressure of the scrotum, together with profound melancholy incident to the patient considering himself subject to serious disease of the sexual apparatus.

He was etherized and a four-inch incision made in the scrotum and sac. A probe could then be passed upward through the patulous but very small calibred unobliterated funicular process into the abdominal cavity. A curved needle armed with strong chromicized catgut was passed through the tissues surrounding this sinus beneath the tunic, avoiding the vas deferens and spermatic vessels, and brought out at the point of entrance. When the ligature was tied down tight an effectual approximation of the neck of the sac at the external ring was secured, and all communication with the peritoneal cavity cut off. The sac was then carefully searched for fibrous or other bodies; none being found, the cavity of the tunic was lightly stuffed with iodoform gauze after its edges had been sewn to the skin margins of the wound by a continuous suture.

The packing was renewed every two days. He arose in five days and returned to work, wearing simply a pad of bichloride cotton held in place by a suspensory bandage, in ten days. The wound finally closed, under stimulation by twenty grains nitrate of silver solution, within three weeks. The result, as demonstrated by the patient to the Section, was perfect, and the man had returned also to a normal mental condition.

### PICKAXE WOUND OF BRAIN.

Dr. John B. Roberts presented a patient who had recovered from a pickaxe wound of the brain, and said:

"The man was brought to me at the Polyclinic Hospital with a small wound of the skull through which brain substance oozed. He had been struck with a pickaxe shortly before admission to the hospital. Within an hour and a half of the injury I laid open the skull, and found pieces of bones driven into the brain. I used the mallet and chisel to cut away the edge of the fracture, and with forceps removed the fragments of bone from the brain tissue. My finger passed nearly an inch down into the brain structure, which was soft. I then washed away, with a stream of bichloride solution, the soft brain tissue. As there was a good deal of oozing from the pia I stuffed a small piece of gauze into the wound to make a little pressure, sewed up the scalp wound at the ends, but allowed the gauze to stick out at the centre. The patient had union by first intention where the edges were sewn together; and second intention where the wound had been kept open by the gauze, which was removed at the end of twenty-four hours. At the present time the wound is healed and the man well. The pulsation of the brain can be seen where the bony wall is absent. It is four weeks since the accident. If trephining had not been done I believe the man would have died of cerebral abscess."

### MISPLACED TESTICLE RESTORED TO ITS PROPER POSITION.

Dr. Edward Martin presented a case of "Misplaced Testicle," the patient being a boy aged nine years. He had the testicle normally descended on the left side, but on the right side it had gone into the perineum, lying an inch in front of the anus. It was freely movable and normal in size. The difficulty, of course, was, that from its false position the gland was exposed to traumatism. The boy had already suffered from one attack of acute orchitis. The history of these cases of misplaced testicle shows that the gland is at first entirely normal in structure and development; but that it finally, simply from chronic inflammation incident to repeated slight injuries, atrophies and becomes useless; hence the great importance of shifting the still normal testicle to its proper protected position.

The only method to be considered in this case was a free incision, division of adhesion, and replacement. The testicle was cut down upon. The cord was dissected free, some dense fibrous bands passing backward toward the anus and being adherent to the epididymis were cut, an opening was made in the tissue of the scrotum, and the testicle was secured in its proper position by two stitches passing through the lower part of the vaginal tunic and the inner skin surface of the base of the scrotum. The long wound was united in a cross direction, thus deepening the scrotal sac. The wound healed without suppuration, and the testicle lies in a perfectly normal position.

The boy now perfectly well and able to ride a bicycle without discomfort.

### PARALYSIS OF LONG RESPIRATORY NERVE OF BELL.

Dr. Martin also reported a case of paralysis of the long respiratory nerve following typhoid fever. During the fourth week of convalescence from typhoid fever it was noticed that the angle of the right scapula became very prominent. This was diagnosed as a dislocation of the scapula—that is, a slipping of the lower angle of the scapula over the fibres of the latissimus dorsi muscle.

On examination it was at once apparent that the serratus magnus was palsied. In addition to its respiratory function the serratus magnus is directly concerned in the movements of the shoulder. By its tonic contraction it holds the scapula, especially its lower angle, closely applied to the chest, and when thrown into full action rocks this bone outward, thus enabling the arm to be carried upward. The deltoid can lift the arm out and up until it is held at right angles to the long axis of the body; the rocking of the scapula by the serratus carries the arm up. Inability to raise the arm higher than the shoulder was well-marked in the case. Under treatment by massage and electricity the patient has recovered in a great measure. He is not absolutely cured, but the outlook is good, as I believe it is in the majority of these cases of neuritis after typoid fever. The photographs show very perfectly both the disability and the wing-like projection of the shoulder-blade.

### CURED FRACTURE INVOLVING THE ATLAS AND AXIS.

DR. M. H. CRYER: This is a specimen of which I do no know the history, except that it was found in a lot of bones when the Philadelphia Dental College was removed to its present quarters. The atlas and axis are held together by bony union. The odontoid process is not in its normal position, but nearly in the centre of the spinal canal of the atlas. From this, one would judge that in displacement of these bones the transverse ligament had been torn and the patient had lived at least long enongh for the bony union to take place, although the spinal cord must have been impinged upon to a very great extent.

### NON-RECURRENCE OF MALIGNANT MAMMARY DISEASE AFTER EIGHTEEN YEARS.

Dr. Thomas G. Morton presented a patient, fifty-six years of age, on whom eighteen years ago he had removed the right breast for malignant disease; the tumor, a rapidly growing one, was large and with the usual characteristic symptoms. Since the operation the patient has had no return of the disease, and continues in excellent health.

### DEMONSTRATION OF A NEW SURGICAL ENGINE.

Dr. M. H. Cryer exhibited an improved surgical engine, with its various shaped drills, burrs, trephines, and guards, used in cutting bone for surgical operations.

The drills are made with three spiral blades, giving them the appearance somewhat similar to a twist drill. The effectiveness of these blades is enormously increased by a spiral screw, forty-four threads to the inch, cut around the blades of the instrument. This device necessarily adds forty-four teeth to the inch upon the edge of each cutting blade. The individual teeth are so arranged with reference to one another that the cut made by one tooth is overlapped by that of the one next following. These instruments are used for drilling into bone and opening the medullary canal, as in the case of osteomyelitis, or in removing sequestra formed in the long bones. After the bone has been cut down upon and the cloaca found, it is opened up wi h the spiral drill and by forcing the instrument laterally the side portion will cut the intervening bone away, thus making a groove down on the dead bone. If the opening thus made is not large enough, burrs of various sizes, made on the same principle as the drills by increasing the number of spiral tooth blades in definite relation to the size of the cutting instrument required, can be used to enlarge the groove to any desired size. These burrs are very useful for removing dead or abnormal bone, uncovering nerve canals for operating on the bony structures in relation to the ear, or in the nasal chamber. For the latter work, Dr. Cryer exhibited a lighter engine made on the same principle as the large one, except that it is made to turn by the foot of the operator.

The most important instruments exhibited were those used for making a section of the brain case. These were of two characters, the circular saw and the spiral osteotome.

The circular saw is one inch in diameter and one-sixteenth of an inch in thickness, having a guard attached to the end of the handpiece to regulate the desired depth to be cut. This instrument has been successfully used in an operation for the removal of the Gasserian ganglion. It cuts with great rapidity, but as brain cases vary in thickness, the operation has to be completed with mallet and chisel. The spiral osteotome overcomes this objection, the cutting portion being made on the principle of the drills already described. It is one-half inch in length, one-eight of an inch in diameter. The point of the instrument when in use is guarded by a rounded button-like attachment connected with the nose of the hand-piece by means of a shank and collar. The free end of the burr is dowelled into a seat in the guard in which it revolves; this steadies the whole instrument when in use, giving added rigidity to the burr shank and holding the burr and guard in permanent relation to each other. The principle involved in the instrument described is simply that of saw cutting in a line with the axis of the shaft of the burr and not at right angles to it as in the circular saw. Such an arrangement allows of cutting in any direction and upon curved lines. This is especially valuable in resection of the brain case, inasmuch as fenestræ of any desired shape or size may be speedily made.

In operating for the removal of a portion of the brain case with this instrument after a division of the soft tissue by the scapel, an opening five-sixteenths of an inch in diameter is made by a trephine mounted in the engine hand-piece; it is passed completely through both tables of the skull and a button of bone removed. There is no danger of injuring the dura with the trephine if it is carefully used. The opening thus made affords a means of entrance for the osteotome, which, with its protecting guard, is next inserted and the section made along the line previously determined by running the engine at a high rate of speed and forcing the bit laterally in the direction desired. The button-like guard at the point of the osteotome prevents injury to the dura, which is pressed or directed away by it from its attachment in the line of the cut as the instrument progresses.

Dr. Cryer made several demonstrations on the bones and head of the cadaver, showing the rapidity with which bone could be divided, and various operations performed, such as drilling and cutting bone, and uncovering the nerves in the superior and inferior maxillæ. The safety with which the operation in opening the brain case was done without injury to the dura was very gratifying. In conclusion he said: "At a meeting of the Philadelphia County Medical Society, held February 14, 1894, during the discussion of an operation for the removal of the Gasserian ganglion by Prof. W. W. Keen, in which this engine had, in my opinion, been successfully used, Dr. John B. Roberts made the following remarks: 'With regard to this elaborate instrument it seems to work very satisfactorily, yet for my own work I should rather use a sharp chisel with my own hand and my own mallet than any mechanical device. These are apt to get out of order and must be at some place where they can be kept in order. What we want to do is to train our own hands to do the work, and not to be dependent upon any mechanical device.' This statement indicates to me an erroneous position with regard to this class of instruments, which it seems to me ought not to go uncorrected.

"With all due respect and admiration for the ability of Prof. Roberts, I am a little fearful that surgery would take a back seat if all its mechanical devices were done away with. I heartily agree with him when he says: 'What we want is to train our hands to do the work,' and I would strongly advocate the highest possible attainment of manual skill as a necessary prerequisite in the performance of all surgical operations; but when he adds that we should 'not be dependent upon any mechanical device,' I am inclined to take issue with him on the ground that his statement is contradictory from the very fact that he himself advocates the use of a mechanical device, albeit a very crude one, in the shape of a mallet and chisel. This machine has now been so simplified and perfected that there is little or no danger of its getting out of order. It is not nearly so complicated as the most simple sewing machine, yet men and women run this, and who would say go back to the ordinary needle and do away with the sewing machine?"

DISCUSSION.

Dr. L. W. Steinbach: I have had the pleasure of having Dr. Cryer perform one of these operations for me recently in a case presenting some difficulties from the fact that repeated operation had been performed on the inferior maxillary portion of the fifth nerve, and I was delighted with the working of the engine, so far as the bone-cutting was concerned, but I do believe that the amount of blood lost was greater than at the previous operations, where the ordinary chisel and mallet had been employed. As a mechanical device I can praise the instrument, and I do not wonder that Dr. Cryer is enthusiastic, but I cannot agree with him that it is a great advantage to a surgeon to learn to use such a complicated machine. It might be of much advantage in a hospital where much work is done.

Dr. Roberts: I was very much interested in trephining with the surgical engine some

fifteen years ago, and wrote an article on the subject after experiments with a flat-headed burr. I am now very fond of the chisel and mallet for opening the skull, using a small sharp chisel shaped like an osteotome.

DR. J. WILLIAM WHITE: I have never had the advantage of seeing this particular instrument used in actual operations, but I can see no theoretical reason why it should not be employed with great advantage to surgeon and patient. I suppose there is no surgeon who does more trephining than Mr. Horsley, of London. I noticed last summer that he employed a powerful electric engine in which he used a burr or saw, and could cut out a section of bone with a great saving of time. It looked to me like a dangerous thing, and it was remarked that there was force enough to drive a part through a man had any portion broken loose. With it, however, he greatly reduced the time required for exposing a brain tumor, did the work with great delicacy and with much less shock (if shock is the result of jarring and concussion of the brain) during the operation than would be inflicted by a mallet and chisel. He, however, cut from without inward. This is the first time I have seen a machine cutting from within outward. We have observed here that it actually pushes away the artery from the bone without injury. I cannot understand why such an operation should be attended with any more loss of blood than by the usual methods, and I do not know why Dr. Steinbach's operation should have been any more bloody. Of course this view is purely theoretical, but as I find a surgeon like Horsley, who is one of the most expert operators on the skull, usuing a machine which seems to me of distinctly less advantage than that the action of which we have just had demonstrated, I believe this engine has a future especially for use in the hospitals, either for nerve resection through bone or for work upon the brain.

DR. M. H. CRYER: I have not much to say, for the demonstration was the principal part, but I am inclined to answer my friend Dr. Steinbach. I believe, from my experience and the experience of others, that in second, third, or fourth operations on the same part one generally has more hemorrhage, for the simple reason that the small arteries are dilated, small capillaries have become arteries through ligating the primary artery, and are therefore more difficult to control.

As to the engine getting out of order, the liability is very slight. It can be run by a child. It is much more simple than the sewing machine, and I should pity the doctor who cannot use this engine. Of course, every device placed upon it makes it a little more complicated, and it requires study and practice to know how to work it. But if I had to remove a portion of the brain case I would not think of using any other instrument at the present time.

## THE MARRIAGE OF SYPHILITICS.

By Wm. G. Porter, M. D. (See page 699.)

### DISCUSSION.

DR. J. WILLIAM WHITE: The general conclusions of Dr. Porter's paper, I think I, in common with all the members of the College, agree with. The three forms he mentions are commonly met with in practice. It is certainly to-day more benign than when many of us began to practice medicine. It is now rare to see the grave variety in which the primary symptoms are soon followed by the tertiary phenomena. If it is true that syphilis is a milder disease than it used to be, it is milder probably in every direction, and we may feel more encouraged than our predecessors to authorize the marriage of syphilitics. It was many years before Dr. Agnew could be brought to say positively that he approved of the marriage of any of his syphilitic patients, and it may be that this slowness on his part was due to the sort of experience with syphilis that we younger men had not had.

It is desirable to formulate some safe rule as to the permission which we are asked to give or withhold in cases of syphilitics intending marriage. Now, the writers who say that as we do not know when a given patient is cured, and as we cannot apply any test which establishes this, we cannot, therefore, give our consent, confuse the future danger of the individual with the possible danger to others, including his offspring. I think it is a confusion which prevails to a certain extent in the profession, and, to a very wide extent in the laity. It is unfortunately true that we are not able to tell a man that he himself will not have further symptoms of syphilis. We may place the percentage of cures very high, and I, myself think, that most of us who treat syphilis intelligently get from 90 to 95 per cent. of cures in the average line of cases. But we cannot select from the 100 cases the five or ten cases that we have failed to cure, and forbid marriage. Nor can we expect to do so until bacteriology has done more for us than it has up to the present. But that has very little bearing, I think, on the question of marriage. Because, as a matter of fact, after a certain time has elapsed, particularly after the combination of circumstances which exist where a patient has had moderate syphilis with efficient treatment, and has gone for a time, two years, say, without symptoms, I think we are very safe in saying there is little danger to others. Personally, I would have the same, but no greater, objection to giving my

consent to the marriage of a man with tertiary syphilis as to that of a man with strongly marked tubercular predisposition, or with mental disease. I think the risk of transmission in the two last named would be far greater than if he had gumma, rupia, or periosteal nodes. I am not aware of any instance, satisfactory to my mind, in which teritary syphilis has been transmitted either to any individual or to offspring. The reported cases are generally defective in some important point. It is difficult where two persons are concerned, particularly in instances of heredity, to be quite sure that the husband has been the parent, and most reported cases are at least open to error in that respect. There are other sources of error, but as a matter of fact, the impression left on my mind is that there is no case scientifically conclusive as to the transmission of tertiary syphilis. I would therefore dissent absolutely from those who believe that no patient with any form of syphilis should be permitted to marry. A man with tertiary phenomena is not likely to have healthy children, nor is the tubercular patient, but the man with tertairy phenomena is not likely to have syphilitic children. And it is safe to say he cannot transmit his disease. Even the fluid of his gumma, or ecthyma, or of his softening node, cannot be inoculated.

His wife may have an occasional miscarriage, or have a child born dead, just as might happen if the husband had chronic alcoholism, or was in the last stage of any grave constitutional disturbance, but she is not likely to have a syphilitic child. That, I believe is the only point in Dr. Porter's remarks on which I have any criticism to make. I think his general rules are admirable. It will surely not do to say that all syphilitics may not marry, because it would certainly result in ruining many lives. I am personally familiar with a great many cases in which unnecessary dread of syphilis has led to prolonged dissipation or melancholia, or suicide. I am now treating a gentleman who has broken off his engagement with an attractive girl; he has given up his business, and is gradually progressing toward the suicidal stage, because he is of the opinion that no man has a right to marry with this disease. He is morbid, of course, and I think he will probably come out of it. But there has no doubt been a great deal of unnecessary alarm. The rules of Dr. Porter are practically those I have adopted, except that I do not require such a long period of freedom from symptoms. In general figures I tell my patients they must wait four years. But if a man at the end of three years has a slight mucous patch I do not, on that account, make the time five years. For fifteen or eighteen years I have been seeing a great many of these cases, and I have from the start followed this general rule. Fournier's book was published about 1878, and was the first well-considered work on the subject which came under my notice. I had been appointed a teacher on syphilis in the University, and I practically adopted his rules then, and have never varied very much from them since. He said in effect that syphilis must have been benign; that a period of three or four years must have elapsed; and that the treatment must have been thorough and complete. I say I have never varied much from them, but as time has gone on I have come to place more and more weight on the one element of time, the period that has elapsed after inoculation, and comparatively less upon the throughness of treatment and absence of symptoms. And I need scarcely say that in that time there have been a great many patients grown up and married, and had children, and I cannot recall an instance where such marriage was entered into with my consent and approval where anything happened to cause me to regret my action. I do not know a single case where, after four years had elapsed before marriage, there was born a syphilitic child. I think that, after all, is the most important thing to discuss. If it is a safe rule, it is an easy one, and we cannot go far wrong in its application. If it is not a safe rule I shall be glad to hear reasons for considering it unsafe.

DR. EDWARD MARTIN: This subject has been very thoroughly traversed by Dr. Porter, Dr. White, and others. The rules governing it are practically common-sense rules dependent upon certain generally accepted facts: Thus every one grants that a man with syphilis not two years old is liable to give the disease to his wife, and to have diseased children, though this is a rule with many exceptions. It is also granted that a man with syphilis three or four years old is *not liable* to convey or transmit the disease; though this rule has a few exceptions. It is granted that a man with syphilis more than four years old is not necessarily cured, since it is impossible to state positively that late manifestations will not appear, but in so far as conveyance of the disease to others is concerned, he can be regarded as safe. This is a rule with very rare and doubtful exceptions. All the reported cases are open to the criticism of Dr. White. The evidence is, however, rather strong to the effect that the disease can be transmitted to the child when it is impossible to directly infect the wife. Finally it is granted that syphilis is a curable disease, though there is absolutely no sign or group of symptoms which can be taken as satisfactory evidence of cure. Reasoning from these rudimentary and commonly accepted beliefs it would seem perfectly proper

to allow syphilitics to marry after their disease has become non-contagious. Probably after two years of continued careful treatment the disease ceases to be contagious in the majority of cases. Not always, however, and it is proper to err on the safe side. The period of four years is that generally allowed, and I have never known a physician who has seen or heard of a case of transmission after this period. Even after four years marriage may not be advisable, not because a patient has had syphilis, or is liable to infect others, but simply because of debility or cachexia there is little promise of healthy offspring. The ground for forbidding marriage would be precisely that taken in the case of consumption. There is an exception which I have made to the general rule of forbidding marriage until the contagious stage of syphilis is passed. Although marriage, perhaps, had for its cardinal purpose, and has still, the propagation of the species, there are many other reasons why it is entered into. There is the element of association, protection, and mutual interest which can be considered quite aside from the sexual aspect of the case. It happens, I think to almost every one, to see cases of buccal chancre acquired by innocent girls from their affianced. I have never hesitated under such circumstances to encourage marriage, warning the patients thoroughly of the dangers of conception, until at least four years shall have elapsed. With this one exception I believe I am thoroughly in accord with the rules laid down by Drs. Porter and White.

DR. ARTHUR VAN HARLINGEN: The remarks I have to make are based only upon my own personal experience. Any man practiced in this class of disease, if he has kept careful note of his cases, must have a certain aggregation of personal experience; and I think that when we bring this experience together it is of a certain amount of value. When the subject of this discussion was first brought to my notice I began to look up the literature, and found that Fournier's work is practically the only one which could be used for reference. In an article written several years ago I based my observations on the work of another French writer, Lancereaux, which I thought excellent from a practical point of view. Fournier, however, is the only author who has given us statistics upon which we can base any conclusions. Aside from this, I think our individual experience is all we can depend upon. The result of my experience is as follows:

In my opinion, it does not seem proper for a man to marry as long as he has any of the secondary symptoms, though I have known immunity to result even in these cases. In my own experience, tertiary symptoms never prove contagious. The man who marries with the secondary symptoms runs the risk of conveying the disease to his wife. With tertiary symptoms I cannot recall any cases in which a man has given syphilis to his wife. In regard to the conveyance of the disease to the child, it has been said it is possible for a man who is in that stage in which the lesions are in all probability not contagious to convey syphilis to the offspring, but I cannot remember any cases in which this has been actually reported. I think it would be advantageous, if any such cases exist, that they should be recorded. Fournier records sixty to seventy cases of syphilitics who married at periods extending from nine to twelve months to a number of years. He reports one case in which the man having syphilis married, and after having three or four healthy children, he himself suffered from tertiary symptoms. His wife was not infected. My own experience is this: I have watched a couple of dozen of cases; I have followed some from five to twenty years, and I should not fear any of my patients marrying after the second year, if they have submitted to a regular course of treatment. I have been in favor of the continuous treatment. My custom has always been to wait until the secondary symptoms occur, and treat continuously. I have treated a dozen or twenty cases from eighteen months to three years. I cannot remember any case in which I have authorized marriage after the second year where the disease has been transmitted. I am aware that this is a much shorter time than is allowed. My own experience is that after the second year healthy children can be engendered. Perhaps the standpoint taken by others is a safer one than that I have taken. I think it will not be very long before some such question will come up before one of our courts of justice. It seems to me a question that we can only decide by uniting our experience, and by each person in private practice publishing his own well-recorded cases. And my urgent advice is that those who see such cases should record and publish them. I cannot see any other way of securing proper data.

I remember the case of a young gentleman who showed the late ulcerative symptoms of syphilis, which yielded very quickly to proper treatment. After the ulcerative lesions had passed away he suffered from that peculiar form of myositis resulting in the contraction of the biceps, which yielded some extent to treatment, but not entirely. He always had a certain amount of contraction. After eighteen months of treatment he asked me if I would allow him to marry. I said I would think it over for several months and then give him my opinion. He did not come back for that opinion. But if he had, and if I had given my consent, the case might have

been brought up before the courts. I wonder what my position would have been if this gentleman had married; if I had given him a written opinion that he would in all probability not transmit the disease to his wife nor have a syphilitic child, and then if the worst had happened? What would have been the expert testimony given by my colleagues? I think that if we could get a body of personal experiences by the gentlemen who see these cases, accurately gathered together, we would have something to go upon. There is really nothing in print except this book of Fournier's. If a case, such as I have mentioned to-night, were to come up before the courts, I do not know what I would have to base my opinion on, except what has been said here this evening. I think it is one of those questions in which the members of the college should publish their opinions, and this, I think, would make a body of evidence which would be of use later on.

DR. HENRY W. STELWAGON: I have listened with a great deal of interest to the reading of Dr. Porter's paper and the remarks by the other gentlemen who have spoken. It is a subject, of course, of large importance and far-reaching. It seems to me in a question of this kind an opinion is to be reached only after viewing it in all its aspects and bearings, basing the conclusion upon aggregate observations, and not putting too much weight upon individual experience. There are certain facts upon which I think all observers are fairly well agreed. One is that during the active and early stages of the disease marriage is tolerably sure to be followed by dire consequences. Another is, that under the most favorable circumstances at least two years should have elapsed between the contraction of the disease and the assumption of the marriage state. Another is, that after a variable number of years syphilis tends in almost all cases, and probably sooner or later in all cases, to lose its infective activity and transmissibility, so that finally there remains nothing of a specific character to transmit. This length of time depends doubtless upon several factors: the type of the disease, which Dr. Porter has referred to; the prior and concomitant health of the individual; his mode of life; and last, but probably the most important of all, the character and thoroughness of the treatment. In syphilis of a grave type, those cases which we see from time to time of a more or less malignant character, the greater possibility of present and future risk should not be lost sight of. The same can be said of the disease occurring in strumous individuals and in other persons in delicate health. The syphilitic addicted to the excessive use of alcohol for a longer time, is doubtless an unsafe husband and procreator. The explanation is to be found in the lessened resisting power. With the exception of these several classes, however, I believe that syphilis is not the grave misfortune it has so often been painted. In the average case of syphilis, occurring in a subject of ordinarily good health, living a temperate life, and who has had intelligent treatment, the power to communicate and transmit the disease is probably, with the exception of a few instances, lost in the course of a few years; and even in the imperfectly treated and neglected cases, judging by general experience, the disease would seem to wear itself out in from two to five years. If this were not the fact, the example of hereditary transmission would certainly be much more numerous than observations show them actually to be. It is, however, the uncertain cases, or the exceptional cases I would say, which give us concern and make us hesitate. And such cases, we are informed by the records, may occur in those who have been well treated and carried out all medical directions, and who are or should be presumably entirely free from all contaminating virus. That such exceptions, according to the records, do occur we must all concede; that they are extremely rare must likewise be granted. It has often occurred to me that some of these exceptions are apparent rather than real, that there may have been good and sufficient reasons pointing against marriage, such as an insufficiently long period of treatment, depraved general health, alcoholism; some may also be attributed to faulty observations, as Dr. White has suggested. I believe myself that persons in good health, of good habits, in whom the disease has been of a mild or average type and has run a favorable course, with no tendency to active recrudescence, and whose treatment has extended over a period of two or three years, during the last year of which there have been no manifestations—that such persons may, if three years or more have relapsed since the date of the contraction of the disease, marry without the slightest risk. Such is the conclusion to which my own observations would lead.

If, however, the question of the marriage of syphilitics is to be viewed purely from a strictly scientific and medical standpoint, and thus necessarily taking cognizance of the rare exceptions and recognizing the possibility of disaster, we should probably feel obliged to refuse our professional permission in all cases. But by so doing we would prevent many happy marriages, damage the socially and politically important family life, and tend, moreover, to encourage immoral living. A liberal view of the question, based upon the broad ground of the public welfare and the knowledge that in proper cases the danger is practically *nil*, would not justify us in such a course.

DR. A. B. HIRSH: There is one phase of the subject which has a half-medical, half-popular aspect, that might be appropriate to mention here, and I refer to a point raised in the discussion by Dr. White, that of syphilomania as occurring in some of the chronic cases coming under our care. We are quite well aware that such cases are apt to occur in the intellectual patient, the man who reads, and not in the average or ignorant dispensary class; such individuals would be apt to have this subject laid open to their inspection by novelists who deal with the more material subjects of the day. It is quite interesting in this connection to know that one of the works which has been most widely read recently deals with this very subject, and individuals suffering from this infection and reading the same would perhaps be confirmed in this very serious view of the subject, and be liable to the mania here discussed.

DR. PORTER: Dr. White seemed to intimate that I possibly thought the tertiary lesions were contagious. I had no such thought at all, and put tertiary patients under the bann, not on account of their generally broken down condition of health, which would not justify marriage.

In regard to the time, the rule which I laid down which has guided me for a number of years is to allow two years to elapse after the disappearance of the last syphilitic symptom. The average period of the duration of treatment is about two years, and that would make the duration the time laid down by Fournier, four years after the inception of the disease. Many cases, however, do well in which the treatment is not prolonged more than a year. At the end of that time, after two years have elapsed, that would make the period three years. The time depends on each individual case.

In regard to statistics, Dr. Van Harlingen has well said that the only thing we know of in the literature on this subject has been written by Fournier, and these statistics, as well as those given by other writers, are very misleading, because it is only within comparatively recent years that syphilis has been so systematically treated as it is to-day, and certainly many of the cases of alleged reappearance of symptoms many years afterward could be explained on the ground of insufficient treatment. I think that statistics could be collected of the modern methods of treatment of syphilis that would show much more favorably than older statistics.

"WHAT did he strike for?"
"Eight hours."
"What did he get?"
"Three months."—*Judge.*

## A Note on Tubercle Bacilli in House Dust.

From *The British Journal,* by R. Shalders Miller, M. B., F. R. C. S. He made an interesting examination of the dust in a house where there had been a series of cases of phthisis.

About fourteen years before the date of making the examination, a man affected with phthisis lived in the house, and left it only a short time before his death. After this an old lady lived in the house for six years, and died there; but not of phthisis.

Then a family consisting of a lady and five daughters took up their residence there; four of the girls being at school most of the time.

In a year the lady became a victim of phthisis. She lived for three years, and then died of the disease.

During her illness the oldest daughter showed symptoms and signs of this disease, but went away from home for a short time, and then returned apparently well, and has remained so.

A few months after the mother's death the second daughter, who had not long left school, displayed similar symptoms; but on leaving home for a time, fortunately made a complete recovery.

In January, 1892, the third daughter, who had left school only at Christmas, and had been suffering from a severe cold, showed consolidation of the apex of the left lung. This girl was not strong, and having had bronchitis when young, the disease advanced rapidly and soon proved fatal.

On several different occasions specimens of her sputum were stained, and showed an ever-increasing prevalence of tubercle germs. Several samples of dry dust, six in all, were obtained from various parts of her home. Of these six samples, five were ruined in the course of preparation. The one still remaining was scraped off the top of the dining-room door. It showed no fewer than eight groups of bacilli, and one of these groups numbered several hundred germs.

After this the house was fumigated and then vacated.

Similar observations have since been reported by a Paris physician.—*Med. Mirror.*

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D., AND SAMUEL M. WILSON, M. D.

THE ARCHIVES OF PÆDIATRICS

for May. Dr. P. B. Bennie has a paper on

**Growing Pains,**

which term he criticises, saying that as his experience increased he made the diagnosis less and less frequently, and found that cases formerly so classified were myalgia, rheumatic fever, occasionally typhoid fever, tubercular arthritis, or adenitis, or some similar disorder in which the pain was so acute that the attention of the patient and friends was attracted to it only.

In many cases a child playing out of doors exhausted itself, and the sharp pains complained of were due to retained products of muscle waste, and readily relieved by favoring the return circulation by elevating the limbs, for a few minutes, and stroking them briskly toward the trunk.

Dr. Charles G. Kerley gives his experience with

**Acute Bronchitis in Infants.**

A large part of the author's observations was among hospital cases, and the general health had been poor, and called often for the continuous use of cod-liver oil, after recovery from the acute disorder.

The treatment advocated is as follows: Ventilating the sick room and keeping it about 70° F., flannel next the skin, and discarding the universal belly-band; frequent changing of position to avoid hypostasis, bathing with lukewarm salt water, preferably at night.

When dyspnœa, hard tight cough, etc., exists, the author advises a steam spray and the use of a sheet wet in hot mustard water (100° raised to 110°), once daily to wrap the child in.

The author believes the spray, and counter-irritation (by mustard paper, camphorated oil, turpentine, etc.), much more useful than internal medication.

A few drops of castor oil are sometimes used at the outset, or a tablet of 1-10 or 1-20 gr. ipecac, with 1-50 to 1-80 gr. tartar emetic hourly; strophantus, or whiskey, occasionally for cardiac weakness, and, in cases of restlessness, bromide, chloral, or Dover's powder in small doses.

Dr. Henry W. Berg writes about the

**Recent Epidemic of Cerebro-Spinal Meningitis.**

The disease is, he says, constantly present in New York; but, during 1893 many more than the usual number of cases appeared. Among the facts of interest noted by him are: That most of the cases occurred in children under five years of age (the rule, he says, in all epidemics); at the time meningitis was most prevalent, pneumonia was also very common, and the diplococcus of pneumonia was one of the most constant of the organisms found in the exudate.

The greater nervous irritability of children is a sufficient explanation for their being more frequently affected than adults. Two members of the same family are rarely attacked, and it is considered safe to treat cases of meningitis in the general wards of hospitals. Bad hygienic surroundings predispose to the disorder, and in other respects the localities infected seem often to have very little connection with each other, a large area of country never being affected, but rather small areas, wards or parts of wards in a city, etc.

In describing the symptoms of the disease the author divides them into—those due to the poison of the disease; those due to inflammation of the cord and its membranes; those due to inflammation of the brain and its membranes.

Cases may die in a few hours, or days, or may last some time, and perhaps recover with serious sequelæ.

Pains in the muscles, etc., occur here as in other fevers; also vomiting, so that the pathognomonic symptom is the cervical rigidity, which may by a jolt or start become a true tonic spasm.

Headache is usually present, so also is fever; but either may be absent, and the author reports a case dying without a temperature at any time above 100.°

The only symptom the author lays unusual stress on is the nasal catarrh, he regards this as a probable explanation of the disease, the patient becoming infected through the nasal passages, and a meningitis developing, owing to the pneumococcus, instead of a pneumonia, and he thinks that in this we have the reason for cerebro-spinal meningitis following influenza.

Eye lesions, the author found rapid in development, and of serious grade.

Dr. George Carpenter reports a case of "Diphtheria from Decomposing Placenta."

The explanation of the curious title is that two weeks after a careful antiseptic delivery the patient developed fancial diphtheria, and, as all sanitary arrangements, etc., seemed of the best kind, all concerned were puzzled to account for the trouble, until a commode was opened and found to contain the placenta, badly decomposed.

Dr. John Thomson (Edinburgh) reports a case of a child contracting "Tænia Circumerina from a Pet Poodle."

Dr. W. C. Cole, of Jacksonville, Ill., describes a case of "Fatal Diphtheria in a Child, Contracted from a Chicken."

THE SANITARIAN,

for May, contains an article by Dr. Wolfred Nelson, on

**Dangerous Practices on the Isthmus of Panama.**

The writer states that it is customary to hire a coffin to carry a corpse to the place of

burial, where the body is removed and buried wrapped in its shroud, and the coffin taken back to the undertakers. Another plan is to rent a burial niche in a building of stone, and so long as this rent is regularly paid the coffin is undisturbed, but as soon as it is overdue "an eviction is in order" and the coffin and contents dumped in a pile, which is burned when its size becomes too great. Still another plan seems to be to reopen a grave and bury another body in it as often as possible; the author having a record, showing that a certain cemetery had been dug over four times in five years.

Other articles in this number are: H. W. Wiley, on

**The Adulteration of Food,**

in which the author uses the saying of Barnum, that "Americans like to be humbugged," as showing one reason why food adulteration is permitted to continue. The author thinks people would frequently rather pay a higher price for an adulterated food sold as pure and of high grade than for the same food sold with the statement that it is an imitation of a really pure article which sells at a price still greater. On this principle he thinks we may explain the reason why persons not directly interested in their sale do not seem eager to have such articles as oleomargerine stamped with a distinctive name when exposed for sale.

The author speaks of adulterations, which make the article sold less useful as food, although not of necessity injurious, and those that are imitations of a more expensive but not necessarily more nutritious or more palatable food.

Very interesting notes are given of the different state laws on adulteration, misrepresentation, etc., of foods, the manner in which these are enforced, and also of the fallacious ideas people in general have of what the most common adulterations are, and to what extent they are carried out. Mention is also made of the uselessness of laws against adulteration which do not provide for careful inspection of samples, and constant supervision by government inspectors.

Under the title

**The Need of a National Health Service,**

the petition of the American Medical Association for the establishment of a Department and Secretary of Public Health is given and discussed at length. The objects to be attained by this department are shown to be not only the prevention of contagious and infectious diseases, but also the supervision of certain industries so as to prevent, or lessen, the occurrence of such nervous troubles as writers' and telegraph operators' palsy, mental disorders of overworked mail clerks, and many others.

From the *Nineteenth Century* is taken an article on "Women as Inspectors."

The article refers to women as members of committees of poor-house inspectors, and snows the result of experience in England in this line. Women are certainly more competent than most men to decide whether the bedding and household utensils are in good condition, and whether or not certain household duties are properly attended to, and since their admission as members of certain boards great improvement has followed their suggestions and supervision.

---

THE VIRGINIA MEDICAL MONTHLY

for May. Dr. Joseph A. White contributes a paper on

**Foreign Bodies in the Air-Passages;**

(nose, pharynx and larynx). In speaking of foreign bodies in the nose and the frequent ineffectual attempts made by the unskilled to remove them, the author says there is no need of anxiety about a foreign body being in the nose, nor of these clumsy attempts to extract them. There is no immediate risk nor danger from its presence, and no occasion for hurry about removing it, if one has not a knowledge of the proper methods and a suitable instrument to use. As a rule there is even no discomfort. The only possible dangers are that a small smooth body might, under some circumstances, be drawn through the nostril, and, by a sudden inspiration, pass into the windpipe; or a rhinitis, sometimes of an offensive character, be set up by any lengthened retention of some foreign bodies. Any physician can easily remove foreign bodies from the nose, even when apparently tightly wedged. A spray of a solution of cocaine will sometimes shrink the tissues sufficiently to loosen it, and gentle traction with a bent probe remove it. The nasal douche, properly used from the nostril opposite the one containing the foreign body, frequently brings it out in the flow of warm water.

In regard to foreign bodies in the pharynx the author states that their removal is an easy matter unless they have passed down to the lower third or into the œsophagus out of the domain of the air-passages. A weak solution of cocaine will relieve all the uncomfortable symptoms.

Foreign bodies in the larynx are more serious than in the nose or pharynx, because of imminent danger of suffocation, if it is not speedily removed, or of secondary troubles from its retention that might cause death. The plan followed by the author is to deaden the pharynx with a 2-per-cent. solution of cocaine by a spray-producer, and then apply a 20-per-cent. solution very thoroughly to the larynx with a brush. He has never been able to do away with the reflex spasm of the larynx with a weaker solution, and sometimes he has had to repeat this application several times in order to do this. In this way he has removed pins, bones, etc., from the larynx without any discomfort to the patient. Sometimes foreign bodies can be successfully removed from the sub-glottic space in the same way. Usually, however, when it has passed into the trachea, if the method of inversion fails, or is impracticable (and it usually is only useful when the foreign body has weight enough to be acted on by gravity, such as a coin), trecheotomy becomes necessary. Even if a small body, such as a grain of corn, or some such substance, has passed into a bronchus, it may be coughed out,

when the trachea is opened, in the first rush of air. If it is not thus expelled, many devices are suggested to remove the foreign body, after tracheotomy, but they may or may not be successful. Its retention in a bronchus may be followed by tolerance for awhile, and subsequently expulsion, of which there are many cases on record; or inflammatory troubles may supervene that will cause death sooner or later.

**Poisoning by Illuminating Gas**

is the title of a paper by Dr. John W. Shaw. The author believes that it poisons in three different ways:

First. By the gas replacing, to a greater or less extent, the atmospheric air, consequently reducing the supply of oxygen.

Second. By the direct poisonous properties of the heavy and light carburetted hydrogen, when mixed with air and absorbed through the lungs.

Third. By the collection of carbon dioxide in the body for the want of sufficient interchange of gasses necessary to remove it.

Which of these plays the most important role in destroying life, the author is unable to say, but he believes that the retention of effete material generated in the body itself is the principal poisoning agent; in reality it is poisoning from the effects of carbonic acid gas, and not illuminating gas. In the treatment the author does not think the inhalation of oxygen has any advantage over a plentiful supply of fresh air. The author thinks that transfusion of blood, when practicable, would be the most rational form of treatment in extreme cases, for it immediately supplies the system with hæmoglobin, of which it is in such great need. This, combined with fresh air, artificial respiration and stimulants, in the form of hypodermic injections of nitro-glycerine, constitute the principal points in treatment.

Dr. Llewellyn Eliot discusses

**The Treatment of Hemorrhoids by Injection.**

The author reviews the various forms of hemorrhoids and the treatment of them by palliative measures. External hemorrhoids may be relieved by the use of laxatives with the application of an ointment or suppository of extract of belladonna and opium, leeching, or a strong wash of tannic acid. Incising and turning out the clot, or a ligature applied, he states, is the generally adopted form of treatment. With internal hemorrhoids palliative treatment is much more unsatisfactory, though many cases are relieved for long periods of time by the use of laxatives, astringent injections, dilatation of the sphincter, and regulation of the diet and avoidance of alcoholic liquors. When hemorrhoids depend upon any disease of the uterus, an examination should be made, and any displacement existing be corrected before operative treatment is instituted. Hemorrhoids occurring during pregnancy sometimes demand operation; and while the pregnant state is not a barrier, it is safer to defer operation until some weeks after delivery. If internal hemorrhoids actually exist, palliative treatment will not cure them; operative treatment alone is what should be adopted. Before any treatment for internal hemorrhoids is adopted it is absolutely necessary that the bowels should be well cleansed. This may be done with calomel, sulphate of magnesia or an enema.

The author then proceeds to review the various methods of operating—the ligature, the clamp and cautery, injection of carbolic acid, crushing, excision, dilation of the sphincter, and Whitehead's operation. Of the treatment by ligature he says that it is the easiest of performance and safest in its results, and is generally accompanied with less pain than any other treatment. Excision is the operation for the expert only. Whitehead's operation is difficult, tedious, and bloody; and if primary union does not ensue, pus accumulates and makes an ugly result. It is therefore applicable to only a few cases. Dilatation of the sphincter muscles cures not so much from the dilatation, but from the fact that it puts an irritable sphincter at rest, for usually there is some abrasion about this muscle. In this condition great relief is felt by its employment.

In regard to the treatment by injection, the author says that notwithstanding all the testimony which has been brought forward against the method, he has never had a bad result from its employment. In every case where he has injected hemorrhoids, there has been a cure as permanent and positive as any result may be called a cure; the hemorrhoids have, as an invariable rule, disappeared, nor has there been a single recurrence of the tumor. The formulæ for the injection which have given him the most satisfactory results are: carbolic acid in glycerine and water of a strength of 12, 15, 33, 50, 95 per cent. To inject hemorrhoids it is necessary to draw them well down, using cocaine anæsthesia if desired; as the sphincter is well dilated this is an easy matter. The needle, not too fine or too sharp, is thrust into the pile and the solution driven in. The author has never limited the injection to a few drops, and has always injected all the tumors at one time. The pain is sometimes great, requiring morphia. Vaseline is freely used and the tumors returned to the bowel. Bleeding has never occurred. A slough forms in three or four days, and is cast off, when there will be found a clean surface with no evidence of a pile. In the cases which the author has treated, rarely has it been necessary for the patient to remain in bed more than twenty-four hours. Usually they are about their rooms sooner.

Dr. Joseph Jones contributes a paper on

**Diphtheria,**

the full title of the contribution being: "Personal Experience with Reference to Diphtheria in New Orleans, La., 1868–1894, also Progress of Discovery with Reference to Nature and Treatment of this Disease During the Past Twenty-five Years." In a former number of the journal the author gave a history of the disease as it has appeared at New Orleans and in this communication he confines himself to points of practical interest as to its origin, hygienic and therapeutic treatment. The author states that he has observed

certain facts which have led him to attribute the propagation, if not the origin of diphtheria, to the filth engendered by milch cows, and also to their milk, in dairies confined to the limits of the city. In support of this view he gives several cases from his records. He also states that he has witnessed cases of diphtheria in which there was no obstruction of the respiration by the diphtheretic membrane, but in which death seemed to result from the direct action of the poison on the heart, and the consequent prostration of the muscular and nervous systems.

The author believes that the Klebs-Loeffler bacillus is the causative agent of diphtheria, and that systemic infection by the diphtheretic poison is not produced directly by the entrance of the microbe into the circulation, but by the ptomaines which have been produced by it. He also states that the use of corrosive sublimate in this disease is not new as it was prescribed by Dr. Tappan in 1860–61. The author states that he cannot subscribe to the large doses and almost reckless manner in which this drug is used. On the other hand, the use of the sulphite and hyposulphite of sodium, in doses of one or two scruples every two hours, both as local and constitutional treatment of diphtheria, appears to be far more philosophical, and should be extensively employed and thoroughly tested.

Dr. W. E. Todd calls attention to the "grave evil that confronts us"—the medical profession—in a paper on

**Proprietary Medicines.**

The writer says: "Medical journals are more to blame for patents and proprietary frauds than the men who read them. With few exceptions, the journals are living from patent medicine pap, and that is why they are slow to raise their voices against the crying evil. I can name hundreds of the vilest patents that are lauded by reputable medical journals for their superior medical properties and their palatableness, when the publisher knows them to be arrant frauds. No wonder upwards of four hundred so-called medical journals can thrive in the United States." The author urges on the doctors of the land to write their own prescriptions and use staple drugs instead of trusting to patent and proprietary preparations.

Dr. C. E. Busey contributes a paper on

**Can Phthisis Be Prevented?**

The author believes that tuberculosis can be inherited and that a tuberculous mother can infect her fœtus with the bacillus present in her own system. In such cases hygienic measures will be of no avail, except possibly to so improve the general health of the child as by the physical vigor thereby established to eliminate the inherited germs of disease from the system. Beside the well-known precautions against infection from the sputa of phthisical patients the author can suggest nothing except the forbidding of marriage between persons who are susceptible to the attacks of the bacillus of tuberculosis by reason of their family history, until they shall have arrived at perfect physical maturity. This, the author concedes to be impossible.

Dr. Wm. A. Thom, Jr., contributes a paper on

**Chronic Bright's Disease,**

with special reference to the causes which produce it. After reviewing the causes of the disease as usually stated in the text books, the author states that he is of the opinion that mind strain from work, worry or sorrow, is a more prolific cause than all the rest. The author's theory is that the kidneys are the emunctories of the brain. The brain, in a constant state of exalted activity, requires the elimination of a quantity of phosphates so largely increased from the normal twelve parts per thousand as to become a "form of injurious matter." All of this work being done by the kidneys, they are then put to a strain under which they slowly break down and take on chronic inflammation and disintegration until they become useless. This action, which the author imputes to the phosphates, would be exactly analogous to that of the urates in the gouty causation of the trouble. The author thinks that this theory would, in a great measure, account for the increased frequency of the disease in late years. In support of this theory the author quotes a case, reported by Dr. E. G. Janeway, of a broker who has had trouble with his kidneys for years. It has been ascertained that when the patient's mind is at rest, albumen tests result negatively, while even the exertion of reading a newspaper will cause albuminous reaction at once.

In regard to the treatment, the author thinks that hygienic measures promise more than others. If alcohol is the cause, abstention from alcohol; if gout, the treatment of the gout; if the too frequent and great elimination of the phosphates, the avoidance of the causes which excite the mind or call for mental labor. Under all circumstances the most careful attention to the functions of the skin and bowels, avoidance of exposure to cold and dampness, and the enforcement of rest. The author has had more success from the use of bichloride of mercury than any other one remedy, though he cannot explain its action. Chloride of gold and sodium may also be useful since it is a tonic, produces sweating and salivation without the mercurial soreness, and is eliminated by the kidneys, where its curative action makes an impression on the connective tissue, and lessens or prevents its overgrowth. In cases where the uræmic symptoms cause emergencies, pilocarpin is probably our best remedy, on account of its rapid action on the skin, but it must be watched for fear the great salivation may become an obstruction to breathing. In this condition, chloroform and chloral are also useful.

**Varicocele**

is the title of a paper by Dr. Stuart McGuire. In regard to the treatment of this condition, the author is of the opinion that the milder forms should be met by palliative treatment only. The mental impression should be combatted by judicious encouragement and

the exciting cause of the trouble determined and removed, if possible. The constitutional tone of the patient should be improved by regulating the habits of life, the use of cold shower baths, and the administration of iron, quinine and strychnia. The scrotum should be supported by some mechanical device, such as a well-fitting suspensory bandage. These measures usually give relief, and may result in a permanent cure.

The author has employed the following operation in five severe cases, with uniformly good results: The scrotum, pubes and thighs are shaved, well scrubbed with soap and water, and irrigated with a bichloride solution. The vas deferens is isolated and slipped behind the other constituents of the cord, and the veins grasped and made prominent by the fingers and thumb of the left hand. An incision about an inch long is made over the cord parallel to its course, and the veins, covered by their sheath, exposed. By means of an aneurism needle, a catgut ligature is passed around the aneurism at the lower angle of the wound, and securely tied. The veins and their fascia are then freed from the surrounding parts for an inch or more above the ligature, and a second ligature passed around them at the upper angle of the wound, and tied. The ends of both ligatures are left long. The portion of the veins between the two ligatures is divided above and below, about a quarter of an inch from the ligatures, and removed. One end of each ligature is threaded on a needle, and passed through the end of the stump which it encircles, and is thus made to emerge at a point opposite the knot. After all bleeding is checked the two stumps are brought together and kept in accurate contact by tying the corresponding ends of the upper and lower ligatures together. The ends of the ligatures are cut short, the wound irrigated and dried, and the incision closed. The next step is the curtailment of the scrotum. The testicles are pushed up against the pubes, and the scrotum drawn through the blades of the scrotal clamp. The clamp is applied from above downward, and care should be taken to depress it well towards the perineum, and to have the raphe of the scrotum in the middle line of the condemned tissue. Interrupted silk stitches are now passed through the scrotum on the distal side of the clamp, and the redundant tissue cut away. The clamp is then removed, bleeding arrested, the stitches tied, and a dressing applied.

In none of the author's cases were there any complications, and the average duration of confinement to bed was ten days.

Dr. J. I. Darby discusses

**The Treatment of Traumatic Epilepsy,**

reporting several cases. The author states that the only remedies to be relied on in the treatment of traumatic epilepsy are the trephine in depressed fractures and the scalpel in other traumatisms which may produce reflex irritation of this character, and when the bone is removed in fractures, the dura should be opened, and if the cortex of the brain shows any signs of injury, it should be carefully cut away. When the bone is not cut away in small bits, it may be replaced in the opening and expected to cause no trouble, provided the button is not thicker than the surrounding bone. After surgical operations for this disease, the patient should be kept on medical treatment for at least two years to prevent a return of the trouble, and it is in this class of cases that we may expect good results. Bromide of potash, in full doses, has given the best results, but a solution of bromide of gold and arsenic has of late given very satisfactory results. The patient should be induced to live a temperate and systematic life, sleeping regularly, eating moderately, and keeping his digestive and excretory organs in a healthy condition. Especially is it necessary for him to abstain from the excessive use of tobacco and alcoholic stimulants.

The author urges on surgeons to prevent these cases by operating on all depressed fractures as soon as seen.

Under "Clinical Reports" there appears the report of a "Series of Twenty-five Abdominal Sections," by Dr. I. S. Stone. One death occurred, due to operation for long-standing pelvic suppuration. In this case the death was apparently due to the action of the ether given. Not a single ounce of urine was secreted during the twenty-four hours that the patient lived after the operation. The autopsy revealed a perfectly satisfactory state of the peritoneum, pedicles, etc. The time of the operation did not exceed forty-five minutes.

Dr. A. W. Bolling reports "A Unique Case of Twin Child-birth." There was an interval of thirty-six hours between the births of the two children, during which time the woman remained free from pain. The second child had been dead in utero for some time, as it was putrid. The woman recovered without any complications.

Dr. S. Walter Woodyard reports a case of "Spina Bifida; A Cure by Iodine Injections."

### For Neuralgia.

For stubborn neuralgia try the following:

℞
Antipyrine..... 5 jss.
Caffene..... 5 ss.
Ext. Cannabis Ind.
Ext. aconite..... āā gr. ijss.
Hyoscyami hydrobromat..... gr. ½.

M. Ft. caps. No. xxx. Sig. One every two or three hours.

---

### Elixir Five Chlorides.

℞
Corrosive sublimate..... 3 grains.
Solution chloride arsenic..... 3 drachms.
Hydrochloric acid, dilute,
Tinct. iron chloride..... āā 1½ ounces.
Ammonia chloride..... 3 ounces.
Elixir simplex.....to make 16 ounces.

M. Sig. Teaspoonful after each meal.

—*Medical Summary.*

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## MEDICINE

### Prognostic Aphorisms: Albuminuria (Warren.)

If albuminuria appears in the course of another affection and persists more than four weeks it is to be feared that albuminous nephritis will be induced and be irremediable.

The existence of albumen in the urine with a diminished amount of urea is a sign of bad omen.

There is but little hope if in the course of an albuminuria the urine is excreted in small quantity, especially if the diminution occurs suddenly.

When the suppression of urine is total (anuria) the end is necessarily fatal.

A diminution in retinitis is a favorable sign.

Amaurosis accompanied with encephalic pain announces a fatal end, imminent and inevitable.

Acute uræmia may cause death in four hours, but, as a rule, in three or five days.

The eclamptic form is less favorable than any other variety.

Microscopic study of the urine by revealing the state of the kidneys is the essential basis of prognosis.

In acute albuminurious nephritis the disappearance of hydropsy without corresponding disappearance of albumen in the urine is of grave portent.

Accidents are imminent if the abundance of albumen coincides with the diminution of the amount of urine.

Bright's disease is always fatal.

Scarlatina in its decline, accompanied with thoracic and cerebral complications due to the existence of albuminuria, is of grave outlook.

The same is true of albuminurious anasarca following measles.

Phthisis and bronchial dilatation are hastened in their course by the appearance of albuminuria.

It is one of the most terrible complications of scrofula and tertiary syphilis.

Erysipelas following in the course of albuminuria is almost always irremediable.

If in the course of a suppurating hematocele or some other chronic affection albuminuria appears the end will be accelerated.

Albuminuria often determines abortion or premature child-birth. If the child is born alive it often dies several days after of eclampsia.—*St. Louis Med. and Surg. Journal.*

### Some of the New Hypnotics for the Insane.

Dr. Granger, in a paper read at a meeting of the New York Neurological Society, said that those drugs were the best hypnotics, which act first and strongest upon the cortex, dulling the sensibilities and lessening voluntary muscular activity, and which influence but little the vascular system and blood pressure. Among the newer hypnotics he mentioned bromal hydrate; he said it was more dangerous than chloral and of but little value. Chloralamid he considered less depressing than chloral, although serious collapse had followed its use. It produces quite refreshing sleep, with no unfavorable after effects. It is not so certain in its action as chloral, and it does not act so promptly. The dose is from 30 to 45 grains. It is useful as an alternative to the other hypnotics. Chloral-ammonium, in doses of from 15 to 30 grains, is said to be non-depressive, and considered a good hypnotic. Hypnal has the reputation of uniting the analgesic effects of antipyrin and the hypnotic effect of chloral. It is useful when sleeplessness and pain are combined and the employment of opium is contraindicated. The dose of the drug is from 15 to 30 grains. Urethan, which belongs to the ethyl group, is useful in the milder cases of insomnia and for purposes of change. Its dose is from 20 to 40 grains. Somnal is an alcoholic solution of chloral and urethan, and of little value. The dose of somnal is 30 grains. Paraldehyde cannot be classed among the newer drugs. It is the only drug, aside from chloralamid, which is comparable with chloral in hypnotic power. These three hypnotics are valuable in all cases of insomnia. Sulphate of duboisin is used as a substitute for hyoscin. It has been said to give more natural sleep and to be less depressing. Sulphonal, tetronal and trional are so closely related that they may be considered together. The first mentioned has marked hypnotic power and seemed, in ordinary doses, to be safe. Its long continued use was, however, dangerous to health. Its action is often slow; it seems to be precipitated in the stomach unless quickly absorbed. Its effect is frequently long continued, the second dose often acting better than the first. It appears to be of little value where sleeplessness is associated with pain. Trional and tetronal are true hypnotics, but alike in many respects to sulphonal. They are all less powerful than chloral.—*Occidental Med. Times.*

### A New Cure for Hay Fever.

Fuber, of Hamburg, who suffered a great deal from hay fever during the summer, noticed that in winter a coryza was accompanied with hot ears, which regained their normal temperature when the discharge from the nose was established. He tried a reverse order of things on the hay fever, and rubbed his ears until they became red and hot. It is now the third summer he has led an endurable existence. As soon as there is the least amount of fullness in the nose, the ears are noticeably pale. A thorough rubbing of the ears has always succeeded in freeing the nasal mucous membrane from congestion. The rubbing must be thorough and repeated.

### Air Embolism.

In the nineteenth of a course of lectures delivered by Dr. David W. Cheever, Professor of Surgery in Harvard University, and published in the *Boston Med. and Surg. Journal*, we find the subject of air embolism treated of substantially as follows: One of the most distressing and rapidly fatal accidents that can occur in a venous wound is the entrance of air. It must be a large vein to admit it. It is sucked in in inspiration. That is the case in the larger veins about the neck, which have no valves, and is especially the case when the mouth of the vein happens to be held open after it is cut by being attached to a fascia, as about the neck, in the popliteal space, in the groin, etc., but especially in the neck. When, for example, the surgeon is engaged dissecting out a tumor in the subclavian triangle, everything is done more easily if the parts are on the stretch. They are out of sight and very probably displaced by the growth of the tumor. The vessels may be enlarged as well as displaced by the long-continued growth.

### Bromide of Gold and Arsenic.

Some months ago a physician of this city claimed to have discovered or invented or introduced a new solution of the bromides of gold and arsenic, published some remarkable cases as cured by the administration of the new medicine and secured a wide notoriety with the aid of some injudicious friends. Shortly after a firm of dispensing chemists in the east secured from this physician a monopoly of its manufacture, and advertised it to the medical world by circulars and pamphlets. The profession is under a great obligation to Mr. Bachmann for the publication of the working formula for the manufacture of this solution. We believe Mr. Bachmann to be the originator of what may be called its revival, and of course he speaks *ex cathedra*. This publication effectually exposes the trade secret which has allowed of a monopoly in manufacture, and puts the preparation within the reach of any skilled pharmacist. The advertised solution is sold for one dollar an ounce. The cost of the ingredients in a gallon of it is less than five dollars, leaving a profit of more than one hundred and twenty dollars on every gallon. If it is as therapeutically valuable as is claimed (which we doubt) Mr. Bachmann has conferred a lasting benefit upon us.—*Pittsburgh Medical Review.*

### Treatment of Eclampsia.

Tarnier (*Journ. des Sages-Femmes*) maintains that eclampsia represents a true poisoning of the blood. It is not caused by retention of urea or carbonate of ammonia in the blood. In eclampsia the blood is absolutely poisonous, as experiment has shown. On this account Tarnier holds that blood must be abstracted in a case of puerperal eclampsia. But then the patient would have less blood (and loss of blood is a great evil under the circumstances), and that blood would be as poisonous from the first as the blood removed. Hence the advantage of a milk diet, which is, to a great extent absorbed, so that the blood becomes diluted, increasing in bulk, with diminution of the proportion of poisonous material. Free purgation is also desirable for ensuring elimination of poison. Tarnier gives croton oil. Inhalations of chloroform are also beneficial; they calm the nerve centres, which are excited by the circulation of poisonous blood, and thus check, in a direct manner, the tendency to convulsions.—*Brit. Med. Jour.*

### For Whooping Cough.

In whooping cough try the following:

℞
Ammon. bromide,..... 3 ij.
Fl. ext. chestnut leaves (Tilden's) .. 3 j
Tr. belladonna..... 3 ss.
Syr. tolu .. ..... 3 ij.
Syr. sim.....q. s. ad 3 iv.

M. Sig. Teaspoonful every two or three hours.

### Ulcerative Endocarditis.

At a meeting of the Biological Society, M. Etienne reported a case of ulcerative endocarditis, which appeared to be due to the bacterium coli. The blood of the heart and of the spleen, collected six hours after death, inclosed the bacillus.—*La Tribune Medicale.*

## SURGERY.

### Suppurating Buboes.

Dr. A. Cavazzani, of Venice, recommends the following powder as a dressing after the incision of suppurating buboes:

℞
Iodoform..... 3 ivss.
Salicylic Acid,
Subnit. Bism.....āā 3 ij.
Pulv. Camph..... 3 ss.

M.

The advantages he claims for it are: 1st. It prevents shrinking of the edges of the wound, so frequent with iodoform, and which so greatly retards cicatrization. 2nd. It rapidly deterges the wound and almost completely suppresses suppuration. 3d. Under its influence the inflammed and tumefied glands rapidly diminish in size, and granulations spring up in abundance, in consequence of which cicatrization is greatly hastened. In many cases where suppuration has been slow and the glands have been inflammed a long time, it is well to curette after the pus is evacuated, but this is not often necessary.

Pontan treats suppurating buboes by puncturing the tumor, allowing the contents to escape, then injecting a ten per cent. mixture of iodoform and vaseline. He claims cure in six to eight days.

### Cystitis.

Dr. Dana praises the action of 5-drop doses of thuja occidentalis every three hours.—*Food.*

Gelsemium is said to be beneficial in irritable bladder, especially in hysterical cases.—*Food.*

### Operative Treatment of Knee-Joint Disease.

Dr. DeForest Willard (*University Medical Magazine*) says:

Mechanical treatment by rest, fixation, and the use of crutches, either axillary, perineal, or ischiatic, is absolutely essential both before and after operation.

In children under twelve years of age, conservative measures should be carried to the extreme, and all operative procedures should tend to non-interference with the epiphyseal line for as long a period as possible, in order to assist growth of the limb. In these young cases, therefore, tenotomy with subsequent fixation should be the primary procedure, to be followed by erasion when necessary, and by excision only when life is threatened.

From twelve to fifteen years of age conservatism should still be the rule, although the dangers from a shortened limb subsequent to operation are not so serious after growth has been completed. In adults operative treatment should be early and more radical in character, erasion still being preferable to excision, except in very degenerated cases.

Amputation should be employed in children only as a *dernier ressort;* in adults with extensive disease it is often a wise procedure.

The introduction of anti-bacillary substances, both extra and intra-articular, offers hope of retardation in the growth of bacilli, but as yet the procedure is in the experimental stage.

After the subsidence of all inflammatory symptoms the late deformity should be overcome.

(*a*) By tenotomy, with forcible replacement.
(*b*) By excision; rarely by osteotomy.

---

### Chloroforming in Sleep.

It is becoming fashionable for burglars to chloroform their victims in the hope that their work will be the more easily and effectually done. As the plan is to administer the anæsthetic while the patient sleeps, it is no wonder that failure attends the effort. Happily it is one of the most difficult feats to accomplish, requiring the greatest care and the highest degree of skill. By many good observers it has been claimed to be impossible. The latter may be looked upon as the rule, especially with novices. Before primary insensibility is obtained the victim awakes from the irritation of the inhaled vapor, when force is necessary for the completion of the purpose. In the meantime the alarm may be given and the assailant may be captured. Fortunately the chances are always against the latter, as his victim, facing the horror of strangulation, is instantly and almost instinctively roused to desperate resistance. Taking all the chances, however, chloroform in the hands of a burglar should be considered as dangerous to its victim as a club, an axe, or a bullet, and its administration should be punished to that extreme limit of penalty which is due to the employment of the other murderous measures.—*Medical Record.*

## PATHOLOGY.

### Gonorrhœa in Women.

Carry (*Lyon Medical*), has made extensive researches amongst prostitutes and fallen women of other classes, suffering from a vaginal discharge. In only one-third of the number was the gonococcus of Neisser detecthd. Carry insists that the gonococcus is absolutely specific of gonorrhœa. It is very easy to recognize, being quite different in form from any other microbe. In four out of five cases its seat was found to be the urethra, in one in five the cervix. The periurethral follicles, the vulvo-vaginal (Cowper's) glands, the vagina, and anus are exceptional seats of the gonococcus. Gonorrhœal urethritis in women is the almost exclusive source of gonorrhœa in man, and the absence of discharge, pain, and local tenderness all tend to hide the source of contagion.

---

## ARMY AND NAVY.

CHANGES IN THE U. S. ARMY FROM MAY 13, 1894, to MAY 19, 1894.

Leave of absence for four months, on surgeon's certificate of disability is granted Major Van Buren Hubbard, Surgeon.

Leave of absence for three months, on account of disability, with permission to leave the Department of Texas, is granted Captain Alonzo R. Chapin, Assistant Surgeon.

---

## NEWS AND MISCELLANY.

### State Board of Medical Examiners of New Jersey.

OFFICE OF THE SECRETARY, No. 319 YORK STREET.
JERSEY CITY, May 21, 1894.

A special meeting of this Board for the examination of candidates desiring to practice medicine in this State will be held in the Capitol, at Trenton, on the third Tuesday of June, (the 19th), *and it will be the last meeting for the examination of candidates held under our present medical law,* as the new law, enacted at the recent session of our legislature, goes into effect July 4, 1894. This new law requires all candidates to have a competent common school education, to be graduates in medicine and surgery which they shall have studied at least four years, and upon which they shall have taken three full courses of lectures, before they can be admitted to the examination for a license, and then all will be subjected to the same examination; it also empowers the Board to accept, in lieu of an examination, the certificates of other State Examining and Licensing Boards, having similar requirements.

Respectfully,
WM. PERRY WATSON, M. D.,
*Secretary.*

## ORIGINAL ARTICLES.

### THE TREATMENT OF DIPHTHERIA.

FRANK E. COUDERT, M. D., Ph. D., Wallingford, Conn.

The proper treatment of diphtheria occurring in childhood and adult life, is a subject of extreme importance to the general practitioner and specialist.

It is not my purpose to enter into the etiology and pathology of this disease; its treatment alone will concern us.

What can I say to impress upon your mind the importance of *prophylaxis;* if not for you rown sake, for that of your family.

Cailte has urged the importance of a careful inspection of the tonsils and mouth in children, special attention being paid to the care of the teeth and to the tonsils, which, if swollen and irregular, should be removed.

In persons liable to exposure, Loefler recommends the use of antiseptic mouth washes, such as Corrosive sublimate (1-10,000), Chlorine water (1-1,100), or Thymol.

Persons sick with diphtheria should be carefully isolated; no one but the immediate attendants should be allowed to come in contact with the patients. Table utensils, bedding, and clothing used by the sick should be thoroughly disinfected by steam or boiling water before being used by others. Intimate contact with the sick, such as kissing, should be strictly prohibited. There seems no room to doubt that the virus of the disease can also be carried in the clothing. Hence, physicians and nurses should be especially careful in personally disinfecting themselves after contact with a case of diphtheria. After death or recovery of the patient, the apartment occupied during the illness should be disinfected with chlorine or sulphurous acid.

Children recovering from this disease should not be permitted to attend school for at least four weeks after recovery.

Proper disinfection in this disease is of the greatest importance and should be carried out faithfully and systematically from the start to the finish. Lime is a disinfectant *par excellence* in this disease. Its strong disinfectant properties are dependent on the following facts, to wit:—

1. As a caustic alkali it destroys all forms of microscopic life brought in contact with it.

2. As a quick lime it has the property of absorbing moisture to an extraordinary degree.

3. During the process of hydration intense heat is generated, which sets up currents in the surrounding atmosphere, and what germs are floating in the air are brought in contact with it and thus destroyed.

Dr. J. Lewis Smith recommends the following as a disinfectant in the disease:

℞ Ol. Cinnamom.....30 pts.
Ol. Eucalyptus.....180 pts.
Ac. Carbol.....220 pts.
Ol. Terebin.....420 pts.

M. Sig. One ounce (℥i) of this mixture in a quart of boiling water, allow it to simmer on a small stove—alcohol being prepared.

Another disinfectant which I think deserving of mention is Bromine. This substance is extremely destructive to all forms of microscopic life. In all cases where there is gangrenous development, Bromine should be used at once. It is not

a specific against the disease, but it is a disinfectant to be used against its local manifestations, and to prevent the infection from spreading. If the patient is old enough to understand what the operation of swabbing is intended for, and will not struggle against it, it is then permissible. Very young children, I think, are better without it, as it is almost impossible to accomplish anything without a severe fight, and as every muscular exertion gives the heart more work to do, heart-failure is very likely to be the result.

When used, Bromine is best administered in the form of Smith's solution. It is made in the following manner:

Take ʒii of sat. sol. Potass. brom.

To this add slowly with constant shaking one ounce of pure bromine, then add very slowly one ounce of pure water. Four drops of this solution contains one drop of pure bromine. There need be no hesitation in applying this solution clear, as it is not caustic. In the proportion of one drop to the ounce of water, it may be used as a gargle.

The general treatment of diphtheria has made very few advances. The pathologist has proven and shown to us the specific germ. What can we say for the therapeutist? He has taught us a little, but not much. He has demonstrated to us that all our efforts to find a specific, so far have been in vain. For want of something better, the old and much overdone Tincture chloride iron and Chlorate potassium is still in use.

Personally I have little or no faith in their virtues. Dr. H. A. Hare, of Philadelphia, says "chlorate potassium should never be used in diphtheria as the kidneys are already inflamed, and this drug is not only useless when so given, but in addition is a renal irritant."

There are a number of physicans who advocate the forcible removal of the exudate. In my opinion the mechanical removal of the membrane is not permissible, unless already partly detached. It is not a difficult matter to pull off a false membrane by mechanical means, but the second membrane has a deeper intimacy with the tissues then the primary. Furthermore any irritation produced by instruments favors the extension of the diphtheritic process.

To cauterize a diphtheritic membrane I consider wrong, for each one of the escharotic sloughs leaves an ulcer, which is a favorite spot for the development of a new membrane in the tissues.

The thing to be accomplished by local treatment is a suppurative process; this is best done by the inhalation of steam or medicated vapor, and the application of hot fomentations to the neck.

The inhalations should be commenced as soon as the membranous exudation is detected, and continued until it has entirely disappeared. The best method of administering the vapor is by the steam atomizer, as found ordinarily in the shops. My experience has been good with hydrogen peroxid. When hydrogen peroxid is brought in contact with mucous membrane or ulcerated surfaces, albuminous coagulation is immediate, with the formation of a white coating and a rapid evolution of gas. It is a very powerful antiseptic, which has been found to be very poisonous to pathogmic germs. The strength may be gauged to suit the case; very often I use the pure peroxid, 15 volumes. By this method of external treatment we accomplish some important factors in the treatment of this disease.

1. We induce mucous secretion, which produces softening of the false membrane.
2. We make the patient more comfortable.
3. The patient receives the medication in this manner without resistance.
4. It can be kept in constant use by any person of ordinary intelligence, and is non-irritating to mucous surfaces of the eye.

The three principal dangers with which we have to contend with in diphtehria are:

1. Heart failure.
2. Systemic infection.
3. Asphyxia from local causes.

Heart failure should be combatted by every known means. All unnecessary handling of a child, sick with this disease, should be prohibited in strong language.

As a cardiac stimulant, alcohol is our sheet anchor, and the amount that a child can take who is suffering with this disease is certainly surprising.

Dr. Jacobi says: "The fear of a bold administration of alcohol will vanish as does that of large doses of opium in peritonitis."

Food in an indirect way is a powerful cardiac stimulant. Hence, proper

nourishment is of great importance. Milk diluted with lime water, beef tea, egg albumen, etc., are all easily taken and most suited to the stomach. Evacuation of the bowels should be had at proper intervals, and if Nature does not accomplish what is demanded of her, artificial means must be resorted to.

Next to alcohol, I depend upon caffeine in doses ranging from one-half to five grains every three-fourths hour. It is a most valuable remedy as a cerebral and cardiac stimulant, and as a diuretic. As a cardiac stimulant it is superior to digitalis in never disagreeing with the stomach, in having no distinctive cumulative tendency, and in the promptness of its action.

The ordinary salts of caffeine are, however, not available for hypodermic use, because they are decomposed in the presence of water. The double benzoate of sodium and caffeine has been proposed as moderately stable and free from irritant properties. The following formula has been commended by M. Fauret for hypodermic use:

℞ Sodium Salicyl.....gr. xxxi.
Caffeine.....3ii.
Aquæ Distillat.....gr. 60.

Systemic infection is best met by the judicious use of Bichlorid of mercury. This is best done by giving 1-32 gr. every hour or two.

Dr. Jno. S. Coleman, of Augusta, Ga., reported a case of a child four years of age, taking seven and one-half grains of this powerful drug in thirty-six hours, at the end of that time she coughed up a whole piece of membrane, which was a perfect cast of the trachea. After this the child went into convalescence, which was rapid and complete.

Bartholow says: "Corrosive sublimate has lately been used with very distinct success in the treatment of diphtheria. Its remarkable germicide property is the motive for its employment, and clinical experience strongly supports the result of experiment."

A few words about the temperature and I have finished. When the fever is high and the skin hot, sponging with tepid or cold water, diluted with alcohol, will be grateful to the patient. If the feet are cold the bath is contra-indicated, and we must resort to internal antipyretics with an increased amount of stimulation, and place hot water bottles at the feet.

If at any time the temperature should become subnormal, a hot bath or pack must be given. Sometimes a hot rectal injection will be of benefit. Great care should be taken when giving very young children cold applications, for as a rule they bear them badly.

Out of the large number of antipyretics at our command, there are only a few which we can use with safety in this disease. Of late I have relied upon quinine and acetanilide combined with caffeine.

By combining caffeine with either of these drugs, we accomplish three things:

1. It improves the appetite and is feebly laxative, owing probably to its action in stimulating the glands of the mucous membrane.

2. Its stimulating action upon the heart and circulation acting more rapidly than digitalis, causing free diuresis in twenty-four hours; it slows the pulse and raises the arterial tension, thus giving a better distribution of blood.

3. Being somewhat anodyne it has a quieting influence upon the nervous system.

# METALLIC TRACTORS AND PERKINISM: A LOST ART IN MEDICINE.

CHARLES B. WILLIAMS, A. B., M. D.,* PHILADELPHIA.

Metallic tractors were small bars of metal which were supposed to have certain magnetic properties and the power of curing various painful affections, and of causing tumors to disappear by being drawn over the part.

The inventor of the metallic tractors was Elisha Perkins, who was born at Norwich, Connecticut, in January, 1740. He received a liberal education from his father, Dr. Joseph Perkins, and finally took up the profession of medicine.

We are told that "he was indebted to nature for uncommon endowments, both bodily and mental. He possessed extraordinary ability to endure fatigue. In person he was six feet high, and of remarkable symmetry. His reputation and success as a physician were considerable, but he is principally known by his metallic tractors."

After long study and numerous experiments, Dr. Perkins, by the aid of various metals, formed two instruments about three inches in length and pointed at one end. The one having an appearance of steel, the other of brass. The mode of application was to draw the points over the affected parts in a downward direction for about fifteen or twenty minutes at each seance.

Dr. Perkins claimed that some remarkable and potent influence was thus brought to bear upon the nerves and muscles. Localized inflammations in the head, face, teeth, breast, stomach; rheumatism, tumors, etc., were all markedly benefited by an application of these little rods, and in some cases the trouble disappeared as if by magic, with no subsequent return of the malady.

Dr. Perkins patented his invention. The success that he obtained was noised even across the Atlantic. It is stated that the professors of three universities in America strongly endorsed Dr. Perkins' views and gave attestations in favor of the remarkable cures that he brought about. "In Copenhagen twelve physicians and surgeons, chiefly professors and lecturers in the Royal Frederick Hospital, commenced a course of experiments, accounts of which were put in an octavo volume." It was in Copenhagen that the term Perkinism arose; the Faculty having so designated this special form of treatment in honor of its discoverer.

In London, a *Perkinian Institution* was established chiefly to benefit the poor by the use of the tractors. But after the institution had been established but for a short time, communications and visits were received from professional men from all parts of Great Britain. It is claimed that professors, physicians, surgeons, and clergymen swarmed like bees in a hive around this new retreat of Æsculapius. Red noses must have been common in those days in England, for it has been estimated that one million five hundred thousand cures were effected.

Dr. Perkins came to New York in 1799, during an epidemic of yellow fever, for the purpose of trying the merits of a highly antiseptic remedy which he had introduced to the notice of the profession, but after remaining four weeks in New York he contracted the disease himself and died, æt. 59.

The writer has in his possession a rare and amusing caricature of Gilray's, that was executed at the time when Perkinism was the rage in London. It represents a follower of Perkins' charming away a *hyperæmia nasi* with his magical "rods of Æsculapius," the metallic tractors. The poor martyr to *podagra*, with a nose that defied even a true "pigeon's-blood" stone for its rubicundity, is seated in his arm-chair, groaning and wincing under the severe operation of having his red nose charmed away by an application of the metallic tractors. In formidable array upon a table at his side a decanter of brandy and a pitcher of hot water are placed together, with a bowl of lump-sugar and a sliced lemon, and all of the necessary paraphernalia for making a "hot toddy" or a bumper of "Hippocras," in which our great-great-grandfathers of the "good old times" were often too prone to

* Ex-Resident Physician Pennsylvania Hospital; Dispensary Surgeon Methodist Episcopal Hospital, Philadelphia.

indulge. Upon his lap lay a smoking, long-stemmed pipe, and a crumpled copy of *The True Briton.* It will be interesting to read the first page of this old English daily. It is as follows: "Theatre, Dead-Alive! Grand exhibition in Leicester Square—Just arrived from America, the 'Rod of Aesculapius.' Perkinism in all its glory, being a certain cure for all disorders: Red Noses, Gouty Toes, Windy Bowels, Broken Legs, Hump Backs; just discovered the grand secret of the Philosopher's Stone, with the true way of turning all metals into gold, *pro bono publico*, etc., etc."

From a merely cursory glance at Gilray's caricature it will easily be seen that this great artist was not, like many people of his time, a firm believer in Elisha Perkins and his magical wands.

So it is with many new discoveries in medicine, like the wonderful panacea "tar water" of Bishop Berkeley, and the *elixir vitae* of the late venerable Brown-Sequard, they will all have their day. Nay, they may even turn the universe upside down for a while, but their fall is assured, and when they do fall, it is always into the blackest oblivion.

## UTERINE FIBROIDS.

CHARLES P. NOBLE, M.D.,* PHILADELPHIA.

In no subject in gynæcology has there been a greater revolution in its principles and practice within recent years, than in that of uterine fibroids. Ten years ago it was universally taught that fibroid tumors or myo-fibromatous degeneration of the uterus, is an essentially benign disease, which seldom if ever causes death, and which in the course of time undergoes a spontaneous cure during or after the menopause. The treatment which was based upon this theory of the nature and course of the disease was a purely palliative one, and consisted in combating symptoms as they arose, by drugs, by hygienic measures, or by minor surgical procedures. When the physician made a diagnosis of uterine fibroids, he congratulated himself and also his patient upon the fact, that as she had a tumor, it was a fibroid tumor of the uterus rather than an ovarian tumor, and that, as a consequence, she would not be obliged to undergo an abdominal section for its removal. It is true that hysterectomy was done at times in those cases in which, in spite of the usual measures employed, the life of the patient was put in serious jeopardy, either by uterine hemorrhages, or by obstruction caused by pressure of the tumor either upon the urinary organs or upon the alimentary canal.

Also, in a certain number of cases, in which hemorrhage was a marked feature, the ovaries were removed in order to bring about the artificial menopause. Hysterectomy was regarded as perhaps the most dangerous operation in surgery, and its inherent mortality was believed to be 30 or 40 per cent.

The foregoing is a fair representation of principles and practice with reference to uterine fibroids which prevailed until within a very recent time. To make the representation complete, it should, of course, be added that when the fibroids became polypoid, they were at times removed *per vaginam.* It is unnecessary to state that the present status of the subject is very widely different from that which has been detailed. This change has been brought about partly by more extended and accurate observation concerning the natural history and tendency of the disease, and partly by the general improvements which have been made in surgery, and more especially in abdominal surgery. The improved results of modern operative procedures could not help but influence the minds of gynæcologists, concerning the possibilities of the operative treatment of uterine fibroids. The old and received opinion that uterine fibroids never cause death was first shown to be misleading. It was demonstrated, and this is, I believe, no longer disputed, that uterine fibroids occasionally cause death directly from hemorrhage; more often indirectly by breaking down the general health and by paving the way for intercurrent disease, either an acute disease, or the chronic diseases which

*Surgeon-in-Charge of the Kensington Hospital for Women, Philadelphia.

attack the feeble, the anemic and the badly nourished. It was also shown that fibroids occasionally undergo degenerative changes, either of a malignant character, more especially sarcomatous degeneration; that they undergo cystic degeneration, in which case the rapid growth and pressure of the tumor brings about death, just as does an ovarian tumor; and, on the other hand, that they undergo inflammatory and necrotic changes, and cause death by inducing septicemia; and, finally, that at times they produce death in accidental ways, as for example, by pressure upon the ureters or upon the bowels; or by offering an obstruction to labor, or by producing *post partum* hemorrhage. The old observations that the menopause in women having fibroid tumors is delayed for from five to ten years has been emphasized, hence a woman who has a fibroid tumor at thirty or thirty-five years of age, has a prospect of menstrual life of from twenty to twenty-five years. It has been further proven that the old teaching that fibroid tumors undergo a spontaneous cure after the menopause is erroneous if taken in an absolute sense, because in a large number of cases, instead of undergoing atrophy and absorption after the menopause, the tumors take on a new growth and develop much more rapidly after the cessation of menstruation than they have done during menstrual life. This is especially true of soft myometa, which are not at all influenced by the menopause. It has also been shown that degenerative changes, either malignant, cystic, or necrotic, are as liable to occur after the menopause as before it.

These facts, which have been briefly summarized, appear to be well substantiated. My own experience so far as it goes, is entirely in accord with the views just expressed. The position of the practitioner at this time must, therefore, be very different with reference to the management of fibroid tumors from that of his predecessor of ten years ago. He must regard the disease as a very serious one, which will as a general rule make a chronic invalid of his unhappy victim, even though it may not cause death in one of the various ways already mentioned. He can no longer hold out to her as an inducement to suffer until the menopause the ills which the disease entails upon her, the assurance that after that event she will become spontaneously well and be relieved of her disease without submitting herself to the risks of an operation, as it has been shown that this is not true in many cases. This inducement was the very basis of the old advice, and was the hope which stimulated and encouraged the many sufferers from fibroid tumors to undergo the years of suffering and invalidism which the disease entailed upon them.

On the other hand, instead of being obliged to say that the removal of the fibroid tumor by hysterectomy is one of the most dangerous operations in surgery, having a mortality of from thirty to forty per cent., he can now say that the operation is no more dangerous than the average of abdominal operations, and that, indeed, it is almost as free from risk as the removal of a simple ovarian tumor. The results of the last few years simply bear out the statement that hysterectomy for healthy fibroid tumors which are free from adhesions, done upon women in reasonably good condition is one of the safest of major operations. The risks of the operation depend upon its complications. Diseased appendages, intestinal adhesions, burrowing of the tumor into the broad ligaments, with displacement of the ureters, necrotic changes in the tumor, malignant degeneration, and suppuration, are the local conditions which are liable to bring about death after operations for uterine fibroids. These conditions, however, are only exceptionally met with, and are found especially in old and neglected cases. The increased dangers of the operation in such complicated cases has, however, only a relative bearing upon the dangers of the removal of healthy fibroids from a healthy peritoneal cavity, and serves as an argument for the early removal of fibroids before such complications and dangers shall have arisen.*

The development of the modern operations for the removal of uterine fibroids

*In order to show that the foregoing statements with reference to hysterectomy have an absolute basis in fact, I have written to Drs. Kelly, Baer and Polk, requesting their recent hysterectomy statistics. The replies follow:

Dr. Kelly reports fifty-seven hysterectomies, two deaths. Dr. Baer, fifty-seven hysterectomies, three deaths. Dr. Polk, forty hysterectomies, three deaths. Adding my own, fourteen hysterectomies, one death, we have one hundred and sixty-eight hysterectomies, nine deaths, or 5.3 per cent. mortality. These statistics mostly extend over the last four years.

(other than polypi) has been along two lines. Koeberlé, Keith, Bantock, Hegar and Price, have been instrumental in originating or perfecting the so-called extra-peritoneal method of treating the stump, using either a wire constrictor—*the serre-noud*—or a rubber ligature, to control hemorrhage from the stump. The work of these men has been of the greatest importance, because of the impetus which it gave to the surgery of fibroid tumors. Within recent years, with the improvements which have been made in the method, it has become applicable in the removal of a very large percentage of fibroid tumors, and the results obtained with it in some hands have been most excellent, the mortality being as low as five per cent. The method has serious disadvantages, however, in that it is not specially applicable to sessile tumors, or to tumors of moderate size which have not escaped from the pelvis, and that in addition to this, it leaves a stump to come away by gangrene, either dry or moist, and requires the subsequent closing of a granulating wound; which fact renders the convalescence from the operation a tedious one, lasting from six to eight weeks, and also leaves a weak spot in the abdominal cicatrix which very frequently results in the subsequent development of a ventral hernia.

The serious disadvantages of this method of treatment led other surgeons to adopt the method of treating the stump within the abdomen. Schroeder amputated the tumor very much as the leg is amputated by the flap method. These flaps were then brought together by a series of sutures, some of which were buried, the effort being made to control hemorrhage by ligatures placed in the tissue of the uterus or cervix itself. In consequence of the contractile nature of the uterine tissue many of these patients bled to death. In other cases, the multiplicity of the ligatures employed produced sloughing of the stump, and death resulted from sepsis. Death from this cause also resulted from the imperfect antiseptic technique employed at that time. As a result Schroeder's mortality was about 30 per cent.

Various operators desiring to avoid the disadvantages of attaching the stump in the abdominal wound, and recognizing the high mortality of the method employed by Schroeder, have made modifications in his method, with the result, that at the present time, the method of treating the stump within the abdomen gives as good, if not better, results than the so-called extra-peritoneal method. Prominent among these operators must be mentioned Kelly, Goffe, Dudley, Chrobak, and last, but by no means least, my fellow-townsman, Dr. Baer. Dr. Baer, more than any one else, has been instrumental in popularizing the method of treating the stump *within the abdomen*, but *external to the peritoneum*, and in showing that the safety of this method depends upon securing the vessels within the broad ligaments, rather than by placing ligatures in the uterine tissue, as was done by Schroeder and all those who came after him. This point of securing the vessels within the broad ligament was first emphasized by Dr. Stimson. He accomplished it by searching for the vessels and ligating them in their course, just as arteries are ligated in other portions of the body. The merit of the operation as done by Dr. Baer, is that he substituted the mass ligature, with which abdominal surgeons are all familiar, so that all the vessels can be secured in a simple and speedy manner.

Progress along the lines laid down by Schroeder has resulted then in the evolution of an operation radically different from his, and which is exactly described as a supra-vaginal amputation of the myomatous uterus, with the intra-abdominal but extra-peritoneal treatment of the stump. The essential improvements over Schroeder's operation are:

1. The vessels are secured by ligating both broad ligaments from the infundibulopelvic ligament to the vagina, instead of by ligatures placed principally in uterine tissue.

2. The uterus is amputated at or about the level of the vagina, leaving but a small cervical stump to be nourished, instead of a considerable portion of the uterus, as in Schroeder's operation, thus lessening the probability of sloughing.

3. Peritoneal flaps which have been stripped off from the tumor in front and behind, are sewed over the field of operation, thus making the wound practically extra-peritoneal, instead of bringing the flaps of uterine tissue together and matching the peritoneal edges, as in Schroeder's operation. After from twelve to twenty-four hours, hemorrhage from or inflamma-

tion of the stump is, extra-peritoneal in the new operation, instead of intra-peritoneal as in Schroeder's operation.

Other surgeons recognizing the inherent risks of the method of Schroeder, and seeking to overcome them, have revived Freund's operation, or total extirpation of the uterus. Polk and Krug of this country, and Martin of Germany, have been leaders in this line of development. They secure the vessels in the broad ligament, in the same manner as in the operation just described, but instead of amputating the uterus at the level of the vagina, they cut through the vagina and remove the uterus entire. In both operations the field of operation is covered over by suturing together flaps of peritoneum, so that an intact peritoneum is left on the pelvic floor after the lapse of twenty-four hours.

The three operations just described are those which are now in general use for the removal of fibroid tumors, and generally speaking, operators prefer to employ one or other of them in the treatment of this disease. In my judgment, however, it is true that they are not applicable to all cases, therefore brief reference will be made to other methods of treatment.

THE REMOVAL OF THE OVARIES.—The removal of the ovaries for the cure or relief of fibroid tumors is not done so frequently now as it was some years ago. The reason is that it sometimes fails to afford relief in all varieties of fibroid tumors; that it has little or no influence upon the development of the soft myomatous tumors; that in some cases it is as difficult and as dangerous as hysterectomy itself; while in other cases, it is not feasible because of the location of the ovaries under the tumor, or because the ovarian tissue has become drawn out by traction over a wide surface, so that the removal of the ovaries becomes impracticable. Although I believe all that has been said concerning the disadvantages of this operation, I still think that it has a small field of usefulness, and practice it occasionally even at the present time. In my hands it has always yielded good results. I consider that its chief field of usefulness is in the treatment of small hard fibroids, which have given rise to such hemorrhages that the patient is so markedly reduced in vitality, that it is not desirable to subject her to an operation requiring more than a few minutes for its performance. In such cases, by bringing about the menopause, the patient is either cured symptomatically or, at all events, is given an opportunity to recover strength, and undergo a subsequent hysterectomy if this proves necessary. Within the past year I have removed the ovaries under these conditions, and some two weeks later curetted the uterus and did a high amputation of the cervix, taking care to put a ligature around each uterine artery. This patient has done well.

LIGATION OF THE UTERINE ARTERIES.—It has been proposed by Martin, of Chicago, and by Gottschalk, of Germany, to ligate both uterine arteries as a systematic method of treatment for fibroid of the uterus. The operation has been advocated especially for the class of cases for which the removal of the ovaries is indicated, because their condition hardly justifies the performance of hysterectomy. This procedure is yet in its infancy, but it promises well as a temporary expedient at least, even though the expectation of its proposers, that it will bring about atrophy of the tumors, is not realized. I was quite prepared to accept this operation by the results I have seen from ligating the uterine arteries in amputating the cervix for procidentia, the uterus rapidly undergoing involution after the operation. I have done the operation twice with satisfactory results.

ERGOT AND ELECTRICITY.—The treatment of fibroid tumors by the use of ergot and by electricity has been tried by the profession and found wanting. Both these agents have a narrow field of usefulness in the management of certain cases, but as a systematic means of treatment, it can be stated that they are not to be depended upon. Certain fibroid tumors have been cured by the use of ergot, more especially the cases of sub-mucous fibroids, by bringing on a miniature labor, and thus expelling them from the cavity of the uterus. The dangers from hemorrhage and sepsis in such cases, however, are far greater than are the risks of hysterectomy. A small number of cases have been reported cured under the influence of electricity, but an analysis of such reports shows that in almost every case the patients had reached or passed the menopause. When, in addition to this, it is remembered that fibroids have been known to markedly diminish in size, or to disappear, after

labor, and after the mere opening of the abdominal cavity, it is not surprising that the same event should, in rare instances, occur after the employment of so powerful an agent as electricity. Not only has electricity proved a failure in causing the disappearance of fibroid tumors, but also unfortunately it has been shown by experience to produce death from sepsis and peritonitis, in a not inconsiderable percentage of cases.

My personal experience in the operative treatment of fibroid tumors has embraced thirty cases. Of these, three were the removal of sloughing fibroid polypi *per vaginam;* thirteen were abdominal sections for the removal of the uterine appendages; and fourteen were abdominal sections for the removal of the tumors themselves by hysterectomy. In the thirty cases there was one death, being the last operation of the series. This operation was a very difficult hysterectomy, in a woman having in addition to the fibroid tumor, double hydro-salpinx. She had been an invalid for many years, had suffered many attacks of peritonitis, and was admitted to the hospital much debilitated from long continued hemorrhages and pain. Death was due to a combination of shock and sepsis, which resulted from the rupture of one of the diseased tubes and the escape of bloody septic fluid therefrom.

Appended are tables of the abdominal operations for fibroid tumors.

The comparatively small number of operations which I have done for fibroid tumors, is evidence of the fact that for a long time I was profoundly influenced in my practice by the old teaching concerning this disease. It was not until my own observations convinced me of the fallacies of past teaching, that I felt justified in resorting to the removal of fibroid tumors, except in the worst class of cases. I am coming more and more to believe, however, that it is the part of wisdom to remove fibroid tumors which are producing symptoms, as soon as they are discovered. In other words, that the principle of early operation, which is now generally accepted with reference to ovarian tumors, is equally applicable in the treatment of fibroid tumors. In this way, women are spared the dangers of possible pregnancy, years of invalidism, and the risk of death from the continued development of the tumor. It will be observed that this general statement does not include the tiny little sub-peritoneal fibroids which are quiescent, and therefore produce no symptoms.

Conclusions.—(1). Fibroid tumor, or myo-fibromatous degeneration of the uterus, is a serious disease, which entails years of invalidism upon its possessor, and which causes death in a not inconsiderable percentage of cases.

(2). Palliative treatment yields uncertain and unsatisfactory results.

(3). Hysterectomy done by either of the three modern methods is a comparatively safe operation, and should be followed by a mortality not exceeding five per cent., in good hands.

(4). The principle of early operation is as applicable in the treatment of fibroid tumors of the uterus, as in that of ovarian tumors. Its acceptance will decidedly lessen even the present mortality of the operation.

[See tables on following pages.]

Case 8.—One large tumor enucleated from under peritoneum. The large oozing surface was packed with gauze, and an opening made in the vagina for its removal. The peritoneum was sutured above the gauze, so that it was extra-peritoneal.

Tumor almost entirely sub-peritoneal. Posterior half of pelvis denuded of peritoneum. Cavity packed with gauze; opening made in vagina; bladder sewed to posterior margin of peritoneum, leaving gauze extra-peritoneal and obliterating the pelvic cavity.

### Table III.

#### Cases of Removal of Fibroid Polypi per Vaginam.

Case 1.—Seen with Dr. Saltmarshe. Single: anæmic from repeated hemorrhages; septic; almost *in articulo mortis*. Sloughing fibroid four inches in diameter removed per vaginam. Recovery; subsequent marriage; maternity.

Case 2.—Seen with Dr. Hess. Married; condition much the same as Case 1; less anæmic but more septic. Sloughing fibroid two and a half inches in diameter removed per vaginam. Long continued sepsis; recovery; subsequent good health.

Case 3.—Seen with Dr. Avison. Married; multipara; condition fair; anæmic. Fibroid polyp removed per vaginam; both uterine arteries tied; recovery.

Exact data concerning these cases not available.

## Table of Cases of Cœlotomies for Fibroid Tumor of the Uterus—Not Including Hysterectomies.

| No. Name. Date. | AGE. | M.S.W. | PAR. | MISC. | DISEASE. | CONDITION | OPERATION. | TIME. | DRAIN. | COURSE. | TEMP. | UNION. | Hospital or Private | RESULT. | Discharge. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1, 28, '90 Mrs. A. (1) | 35 | M. | 4 | 2 | Uterine fibroma. | Worn. | Cœlotomy: left uterine appendage removed. Right not removed owing to a torsion of the uterus. | 40 min. | 48 hours. | Uninterrupted. | Afebrile. | Primary. | Hospital. | Recov. | 2, 2, '90 |
| 4, 15, '90 Mrs. B. (2) | 44 | M. | 2 | 2 | Uterine fibroid and double hydrosalpinx. | Fair. | Cœlotomy: removal of both uterine appendages. | 40 min. | 50 hours. | Phlebitis 3d wk mild | Slight fever 3d w'k. | Primary. | Hospital. | Recov. | 5,13,'90 |
| 10, 15, '90 Miss W. (3) | 30 | S. | 0 | 0 | Uterine fibroid. | Anæmic. | Cœlotomy: removal of both uterine appendages. | 20 min. | 48 hours. | Uninterrupted. | Afebrile. | Primary. | Hospital. | Recov. | 12,20,'90 |
| 3, 23, '91 Miss L. (4) | 17 | S. | 0 | 0 | Utertne fibroid. | Good. | Cœlotomy: exploratory operation abandoned. Bladder anomalous extending to within one inch of the umbilicus. | 30 min. | None. | Uninterrupted. | Afebrile. | Primary. | Hospital. | Recov. | 4,27,'91 |
| 9, 5, '91 Miss M. (5) | 33 | S. | 0 | 0 | Uterine fibroid with cyst of left ovary. | Good. | Cœlotomy: removal of both uterine appendages. | 30 min. | 48 hours. | Uninterrupted. | Afebrile. | Primary. | Hospital. | Recov. | 10,3,'91 |
| 11, 5, '91 Miss M. (6) | 30 | S. | 0 | 0 | Uterine fibroid with cyst of left ovary. | Fair. | Cœlotomy: removal of both uterine appendages. | 35 min. | None. | Uninterrupted. | Afebrile. | Primary. | Hospital. | Recov. | 12,5,'91 |

## OPERATION FOR FIBRO-CYSTIC SARCOMA INVOLVING THE RIGHT INFERIOR MAXILLARY BONE.*

J. McFADDEN GASTON,† M. D., ATLANTA, GA.

A colored woman, thirty-five years old, with regular menstruation, and having borne several children, enjoyed general good health until a tumor made its appearance some years ago, for which she underwent an operation for partial removal of the right lower jaw. She presented herself with a reproduction of the growth at the clinic of the Southern Medical College on January 24, 1894, and upon examination I found a large mass involving the region from the angle to the mental curve of the right lower maxillary bone, extending upward to the zygomatic arch and inward to the root of the tongue. There was a protuberance of indurated substance in the middle and a tense elastic portion above, with a larger formation of the same character below. The two last named developments were evidently cysts, while that which lay between them gave the impression upon palpation of the consistence of cartilage. The entire cavity of the mouth on the right side was filled with the tumor. There is a cicatricial line extending from the middle of the lower lip along the margin of the right jaw to near its angle, which indicates the incision made in the previous operation performed about two years ago. The patient states that the growth commenced some years prior to that time. The exact limits of the primary growth, or the details of the extent of the measures adopted by the former operator, could not be accurately ascertained, but it is evident that all the diseased structures were not removed, and hence the redevelopment of the tumor. The indications led to the view that the new growth was a fibro-cystic sarcoma, and that its early removal was the only chance for prolonging the life of the patient. Upon informing her and her husband of the certainty of a fatal result without operation, and of the risk to life from the removal of the tumor, they took the matter under consideration, and subsequently notified me that she would prefer to avail herself of the operation before the medical class.

Accordingly, she was instructed to take two compound cathartic pills night and morning to procure free evacuations from the bowels, and to refrain from food on the morning of the 31st of January, preparatory to undergoing the operation at my regular clinic on that day.

The field of operation having been thoroughly cleansed, a hypodermic of one-fourth grain of morphine and one-one hundred and fiftieth grain of atropine was given, and she took an ounce of rye whiskey with a little water, after which the A. C. E. mixture was inhaled from an ordinary towel cone, until she was fully anæsthetized.

With the assistance of Drs. L. B. Grandy, E. C. Davis and J. McF. Gaston, Jr., I proceeded with the various steps indicated for the complete removal of the tumor with the jaw-bone. At the outset a strong silk ligature was passed through the tongue and its ends knotted together, so as to form a loop, which was to be made available to prevent the tongue from dropping back and interfering with respiration at a subsequent stage of the operation. This precaution is made requisite from the record of cases in which suffocation has resulted from its omission, when the lateral attachments of the tongue have been severed.

The next step was the extraction of two of the lower incisor teeth, where it was expected to divide the thick bony structure subsequently, either with the saw or bone forceps. This would effect its detachment in front and another section behind the angle of the jaw, through the condyloid neck would separate the bone behind, so that all the intervening portion of the lower maxillary bone on the right side should be detached with the tumor. It was supposed that the facial artery had been ligated in the former operation, and hence that its trunk was obliterated, but that the collateral circulation had been established to some extent by the an-

*Read before the Medical Association of Georgia, in Atlanta, April 18, 1894.

†Professor of Principles and Practice of Surgery, Southern Medical College. Ex-President Southern Surgical and Gynæcological Association, Etc., Etc.

astomosing vessels, so that some small branches would be encountered in proceeding with the dissection. It may be noted, however, that in the removal of malignant tumors, the nutrient vessels have been found usually so small as not to require ligating, and even the regular supply of arteries generally undergo atrophy to a considerable extent in the vicinity of the neoplasm, owing, perhaps, to compression.

My greatest concern in regard to hemorrhage connected with this operation was relieved by the expectation of leaving the condyloid process and thus obviating the risk of wounding the internal maxillary artery by its removal. This vessel lies in such close proximity to the inner face of the bone that the steps for its disarticulation require great caution against wounding it, and it branches off from the external carotid so that ligation is difficult. Having planned to accomplish the incision and dissection, so far as possible, without entering the buccal cavity, and thus avoid the entrance of blood into the fauces, I first divided the skin from a point immediately below the middle of the lower lip along the line of the cicatrix from the former incision back to the angle of the right lower jaw, and thence upward to the prominence of the zygoma, keeping away from the temporal artery in front of the ear. The skin was then dissected back on the lower side from the tumor and in like manner above to the zygomatic arch, thus exposing the exterior surface of the diseased structure without entering the buccal cavity. The few cutaneous arteries which were divided were secured with artery forceps in the course of the dissection on the lower border.

At this stage, the lip which had been left intact in the first incision, was divided and the tissues separated from the bone until the point was reached for its detachment.

Having incised the periosteum over the surface of the lower maxillary, on a line with the socket from which the incisor was extracted, a saw was passed over the outer surface of the bone and then a strong pair of bone forceps was used by Dr. Grandy to divide the bone from above downward. I then used the same forceps to separate the bone just behind the angle and proceeded to dissect up the close attachments of the masseter and temporal muscles from the coronoid process. This left the resected portion of the lower maxillary imbedded in the tumor and all could readily be lifted up so as to complete the separation of the mass from below. In making the incisions up to this point, very little if any blood had entered the mouth, and it is desirable in doing this operation to provide against entering the buccal cavity as long as possible; but it was requisite at this stage to go into the month, and entering it from below I avoided trouble from the blood. Proceeding with the dissection around the lower large cyst, curved scissors were used, keeping close to the sac, while the whole mass was lifted upward so as to get a good view of the dissected structures; but notwithstanding all my precaution the sac was opened and the brownish fluid contents escaped in quite a stream from the external wound, thus lessening very notably the size of the tumor. It was thought best in view of this to cut through the coats of the sac, leaving the deep attachment to be dissected out after the diseased mass was so far detached as not to interfere with its removal. This portion of the sac in the deepest part of the excavation was in close proximity to the pharnyx, and in dissecting it from the surrounding tissues an arterial branch was cut, which was immediately seized with the forceps by my son and was subsequently ligated with catgut and dropped. It may be here stated that this was the only blood vessel which necessitated ligation in the course of the extensive incisions for the removal of the tumor.

I had provided an aneurismal needle armed with a strong silk ligature to secure the external or the internal carotid if the branches of either should be cut without being able to seize the divided vessels. The Pacquelin thermo-cautery was kept aglow by Dr. Davis to arrest any superficial oozing which could not be controlled by sponges with hot water. Thus, armed against any contingency I went forward with the excision from above, enucleating the upper cyst from the zygomatic fossa and the indurated mass of cartilaginous consistence from beneath the arch. Having completed the separation of the entire tumor, I was agreeably surprised to find that there was but little sanguineous exudation from the surface of the tissues involved in this deep incised cavern. The oozing soon ceased under the hot water applications and cleaning out the mouth and throat with a sponge probang,

the artery forceps were removed from the small twigs without any appearance of a jet of blood to require ligation. A loose compress of sterilized gauze was packed into the cavity with a strip out at the mouth. Depending upon the contractility of the skin to bring the flaps into proper relation for covering the wound, no part of it was excised, and the only notable fact upon bringing the cutaneous investment in apposition was the very decided lack of the normal temperature in the large upper flap. This caused some apprehension as to preserving the vitality of the tissues with the limited blood supply to the narrow base. But recalling an observation, in a plastic operation for building an artificial nose from flaps dissected out of each cheek, in which there was not only a loss of heat, but shriveling of the structure on one side during the first twenty-four hours and eventually complete restoration, I was hopeful in this case. The interrupted silk suture was commenced by me at the lip and by Dr. Gaston, Jr., at the remote end of the incision over the malar protuberance, bringing the parts accurately together so as to favor the restoration of the circulation at the earliest practicable period. After passing below the cuvilinear approximation, the union of the rectilinear incision along the former site of the body of the lower jaw, which had been removed, was affected with catgut stitches at a greater distance apart than the other suture. A broad strip of adhesive plaster was applied from the surface over the left lower maxillary along this line of catgut suture to the mastoid process on the right side to maintain a degree of fixidity in the parts.

The entire surface was covered with iodoform gauze and absorbent cotton, secured by turns of a roller bandage.

In the meantime, notwithstanding the slight loss of blood, there were such indications of shock as to require the resort to frequent hypodermic injections of whisky, alternated with nitro-glycerine and digitalis. The anæsthetic was discontinued after the detachment of the tumor, and vigorous measures were requisite to avert a fatal prostration. In addition to the above enumerated means, hypodermic injections of one-fiftieth of a grain of strychnine were repeated every half hour until one-tenth of a grain was given, and afterwards every hour until reaction was established.

After removing the patient from the operating table, bottles of hot water were applied along the lower limbs and on each side of the body continuously for several hours.

The pulse for a time was feeble and rapid, but five hours after the completion of the operation it counted but fifty beats to the minute, and the patient was still unconscious and in an extremely prostrate condition.

The favorable result of perseverance in the use of hypodermic injection of strychnine in this case adds another to the many instances in which this agent has been employed to avert profound collapse. While other drugs are transitory in their influence over the nerve centers, and should not be discarded in remedies for shock, there is nothing so trustworthy for its staying properties as strychnine.

I have no personal acquaintance with the virtues of camphorated oil, which Dr. Christian Fenger, of Chicago, and others have employed to a large extent under similar circumstances, but aqua ammonia strikes me as preferable to it. Having used the precaution of administering a hypodermic injection of morphine and atropine with a drink of whiskey to the patient before giving the anæsthetic of A. C. E. mixture, and there being less than five ounces fo blood lost during this operation, it was not anticipated that it would be followed with such marked vital depression. It is only a further illustration of the unknown factor which enters into the equation of shock, and there is no field of investigation which calls for the attention of the profession with greater urgency than this overpowering effect of surgical procedures upon the nerve centers. If the link of correlation between injury to the ramification of the nerves in the tissues and the great nerve centers was properly comprehended, it ought to throw some light upon the means to be adopted for the prevention of shock. After considerable study of the nervous system I realize the utter impotence of the operator in attempting to carry out any prophylactic measures against shock, and this subject is commended to the careful consideration of neurologists.

On the day following the operation there was considerable debility, but entire restoration of consciousness and ability to swallow fluids. The dressing was only lifted to ascertain the state of the upper flap, and it was found to have regained the

natural warmth throughout the entire line of union in the cutaneous wound.

During the second day there was marked reaction, and the traumatic fever was attended with a temperature of 102° F., and a pulse of 120 beats to the minute. The dressings having become saturated with the sero-sanguinolent discharge, were renewed, and the packing was removed through the mouth by drawing upon the strip which protruded. The entire inner surface was wiped off by a piece of gauze, wrung out of a mixture of one ounce of spirits of turpentine and one dram of camphor, and a tampon of the same left packed into the zygomatic arch and into the bottom of the cheek. All the tissues of the large upper flap were somewhat swollen and thickened, so that the space within was not so large as immediately after closing the wound.

Upon the third day the pulse reached 130 beats to the minute, and the temperature 103° F., but the general condition of the patient was good, and she drank milk with Mellin's food during the day. The dressings, not being much soiled, were not disturbed, and as the ligature in the tongue did not seem to cause any trouble, it was allowed to lay in the left corner of mouth loosely attached to the dressing. She took one-half ounce of Epsom salts.

On the fourth day the temperature ranged from 103° to 103.5° F., with a pulse varying from 130 to 135 beats to the minute. But the patient seemed hungry, and took, in addition to the Mellin's food, milk punch and chicken soup. She even craved bananas, but was not indulged in this. Her urine was normally evacuated. The dressing was all renewed, and the cleansing of the inside was repeated with the camphorated turpentine, but the packing was done with plain gauze. She had little difficulty in swallowing, and the bowels not being moved, the Epsom salts was repeated with good effects.

The fifth day brought no marked change in the condition of the patient, except that her pulse was weaker, and vital power seemed to be less, accompanied with some dullness of perception when spoken to. She was ordered milk punch at frequent intervals, and beef tea every three or four hours. The dressings were not much soiled, and were not disturbed. Her bowels had been moved on the previous day, and she had passed urine during the morning.

Upon visiting the patient on the following day, February 6, there was notable coma, with pulse of 110 beats to the minute and temperature of 110° F., and upon inquiry as to the discharge of urine it was found that none had been passed since the previous morning. Upon using the catheter my son drew off about two pints of urine, which presented nothing unusual in appearance, but no test of it was made.

Upon removing the dressing, the strip of adhesive plaster which had been carried from the left jaw along the line of incision to the mastoid process, was detached, and the union by first intention had taken place throughout the entire cutaneous wound. In removing the gauze packing through the mouth there was evidence of sensibility, notwithstanding the obtuseness of her mental condition. The interior surface of the wound was swabbed off with gauze wrung out of camphorated turpentine and packed as before with dry sterilized gauze with a strip protruding from the angle of mouth. This formed drainage, and was intended to facilitate removal of the tampon, should it have any tendency to drop back into the throat. The ligature through the tongue had not been required at any time to prevent this organ from falling into the fauces and obstructing respiration. But as it caused no trouble, the loop was allowed to remain in the left corner of the mouth, secured to the external dressing of iodoform gauze. She took milk punch after the dressing was completed, but there was some difficulty in swallowing it, due to the progressive coma. With a view to an alterative and tonic effect, the following prescription was given during the day:

℞

| | |
|---|---|
| Huxham's tincture | f ʒ ii |
| Tinct. nux vomica | f ʒ i |
| Chlorate potash | ʒ i |
| Water, q. s | f ʒ vi |

M. Sig.: Take a tablespoonful every three hours.

In the interval she was ordered to take whiskey toddy and milk punch.

There was a steady increase of coma, with a gradual decline of vital force until the death of the patient at five o'clock, P. M. of the same day, six days and four hours after the operation.

With the favorable state of the wound in the progress of this case, and the final retention of urine, I am disposed to consider the coma of uremic origin, but have no sufficient data upon which to base this opinion. The cause of death was given as septicemia in my certificate.

# OPERATION FOR ANCIENT DISLOCATION OF ELBOW AND BRIDGE OF CALLUS BETWEEN RADIUS AND ULNA.

JOHN B. ROBERTS, M. D., PHILADELPHIA.

The patient had an old dislocation of the elbow, which occurred two years ago, and was the result of a fall from a carriage, which was overturned. The injury was evidently a backward dislocation of both bones of the forearm, with compound fracture of the radius at the junction of the upper and middle third. The injury occurred two years before the patient, who is exhibited, came under my care at the Woman's Hospital. She at that time had the right arm rigidly extended with no motion at the elbow; suffered with pain and numbness in the fingers at the ulnar side of the hand, due to presence on the ulnar nerve, and had a suppurating sinus at the point of depression, shown in this cast made of the arm before operation.

It seemed to me that it was proper to attempt to treat the old dislocation, although of two years' standing, by making a resection in order to get the arm in a flexed position. I cut down upon the olecranon, and found that the head of the radius and the olecranon were soldered by callus, to the humerus, in the abnormal position. The ulnar nerve was displaced and in a condition of tension. I was compelled to chisel loose the radius and ulna and cut off the triceps tendon in order to put the bones at the elbow in the position of flexion, which would be so much more useful and convenient, even if the elbow were immovable. In order to unite the triceps tendon to the ulna after flexing the joint, I was obliged to lengthen it by cutting a V-shaped flap out of the tendon. This I did with its apex upward, and then turned the flap over with its point downward, and sutured it to the stump which had been left attached to the olecranon. I used silk sutures. I lessened the tension on the ulnar nerve by replacing it; in the course of a few days the numbness of the fingers disappeared.

In order to cover in the gap in the skin, I made a large plastic operation by dissecting a flap from the forearm. Her arm was now fixed at a right-angle, and in the course of, perhaps, two months, I got a considerable degree of motion. The radius and ulna were still united at the seat of the sinus by a bridge of callus, which prevented pronation and supination. I therefore determined to cut down and chisel out the bridge of bone and see if I could establish pronation and supination. Upon cutting down I found a sequestrum due to necrosis of the radius at the point of fracture. I chiselled away a considerable amount of bone and took out the dead portion of the radius. Knowing that the head of the radius would not be likely to rotate, as it had no cartilage upon it, I determined to make an artificial joint in order to get some pronation and supination in addition to the amount of flexion already obtained at the elbow. I excised three-quarters of an inch of the radius, and then encouraged the girl, after I had removed the portion of bone and the wound had partly healed, to make motions of rotation of the hand.

She obtained a certain amount of *passive* supination and pronation, and the fingers became more flexible. During our endeavors at making passive extension and flexion of the elbow, fracture of the ulna took place, some weeks later, in the upper third of the shaft. This necessitated putting her arm in a splint and prevented our continuing with the massage and other motions to get motion at the elbow and wrist. As the elbow would probably become stiff, I, in order to get the hand more toward the face, allowed the fragments to unite with a little angularity. You see now a bend or angular deformity at the seat of fracture, which enables her to bring the hand nearer the mouth than otherwise would have been possible. The wound has not entirely healed. She lost nearly all the flexion and extension she had from the first operation during immobilization of the joint for repair of the fracture of the ulna. She has a little motion at the elbow, not enough to be useful; there is practically no supination or pronation of the hand, but the numbness of the fingers is gone, and she can bend her fingers, which were stiff, pretty well. She has, and had, good motion at the wrist. We have not gained a great deal, therefore, except the right-angle position of the elbow, motion of the fingers, and freedom from pain and numb-

ness. If fracture had not taken place, I think we would have obtained considerable motion at the elbow, and have been able to maintain the false joint at the point of radial resection so at to give her some rotation of the hand.

The case is interesting to me because of the lengthening of the tendon of the triceps, the attempt to establish a point of motion in the shaft of the radius, when the head is adherent by ankylosis to the humerus, and the ease with which bridges of callus uniting the radius and ulna can be removed.

## DELAYED UNION IN FRACTURE.

THOS. G. MORTON, M. D., PHILADELPHIA.

In these days of antiseptic surgery, we are, perhaps, a little too hasty in regard to the treatment of delayed union in fractures, and do not give Nature time to effect repair. The length of time taken for repair was unusually long, yet the result in both cases here reported has been perfect.

CASE I.—*Delayed union in a fracture of the femur.*—(Notes of Dr. Wm. H. Shipps, of Bordentown, N. J.) On January 20, 1893, L. M., a young woman, seventeen years of age, while coasting, was violently thrown from a sled, sustaining a fracture of the right femur at about the junction of its middle and lower third. She was at once carried to her home, placed upon a firm mattress and sandbags and extension by weight and pulley employed. The patient, an intelligent girl, recognized from the start the importance of keeping the fragments in position, and labored in every possible way to avoid disturbance of the limb; so determined was she in this respect, that she avoided in so far as possible, a regular evacuation of the bowels, although assured of the folly of such a course. Having a most capricious appetite, it was difficult for the first six weeks to get her to take a sufficient quantity of nourishment, although the necessity for this important aid in bone repair was constantly urged upon her.

At the end of four weeks the dressings were removed and the limb carefully inspected. No shortening was detected, but to my chagrin, no attempt at union had taken place, notwithstanding the parts were in perfect apposition. The dressings were carefully reapplied.

On March 20, two months after the injury, an examination showed entire absence of bony union. At this juncture I requested Dr. Morton to see the case with me. It was agreed to resort to daily massage of the entire limb, especially in the vicinity of the fracture, and to lessen the amount of extension. The limb was also encased in a firm dressing made of two Russia felt splints; a posterior one, extending from the great trochanter to within six inches of the ankle; an anterior, extending the entire length of the thigh, firmly held in place by a roller bandage. Four weeks later the patient was allowed to get out of bed daily and walk about on crutches, care being taken that no weight be borne upon the limb. This plan of treatment was faithfully carried out; the appetite of the patient in the meantime materially improved.

In the course of three weeks the circumference of the limb had visibly increased, and an evident attempt at bony union noticed.

From this on the limb gradually improved in size and strength, until at the expiration of eight weeks from the commencement of massage, at which time Dr. Morton again saw the case, consolidation was complete. The dressings were continued for a few weeks longer, when a single roller bandage took the place of splints. Careful measurement of the two limbs at this time failed to show any appreciable shortening. Altogether the case made a most satisfactory recovery.

CASE II.—*Delayed union in fracture of the leg.*—On August 1, 1893, Captain A. S., aged fifty-one years, while at Ivigtut, South Greenland, in command of his vessel, received an injury to the right leg by the fall of a bulkhead or partition which separated the cargo of kryolite from the ballast; a medical man from the shore who was summoned, found the left leg seriously crushed, and an oblique fracture of both bones about the junction of the middle and lower third; he applied

temporary pasteboard splints, and the patient was hoisted from the hold. Four days later, bandages, pasteboard splints and a plaster dressing were applied. Three weeks later the swelling of the limb had so subsided that he observed not only a considerable movement, but a grating of the bone; six weeks subsequent to the injury the dressing was removed when it was found that there was little if any union; posterior board splint was applied, and two weeks later he left Greenland and arrived in Philadelphia on October 17th, seventy-eight days after the accident; he then entered the Pennsylvania Hospital. General condition good. The limb was greatly swollen, skin dry and rough, evidently no attention had been given to the condition of the circulation, for the limb had not been out of splints for many weeks, and had not been bathed since the accident; there was little if any effort at repair in the fracture. Attention was first directed to improving the circulation of the limb by soaking in warm water and by massage; fracture box; subsequently Russia felt splints; finally a brace was applied. He was discharged December 11, 1893, with considerable union, which was not firm until the close of January, when he was able to walk without any support.

# TRANSLATIONS.

## THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

### A LUBRICANT FOR URETHRAL INSTUMENTS.

Prof. F. Guyon (*La Semaine Médicale*, No. 18, 1894) offers the following as an efficient lubricant for urethral sounds, etc.:

℞

| | | |
|---|---|---|
| Powdered Soap | 50 | 0 (℥j ¾). |
| Glycerine | | |
| Water, ana | 25 | 0 (℥vj). |
| Corrosive Sublimate | | 02 (gr. 1-5). |

This preparation is aseptic and does not irritate the urethral mucous membrane. It greatly facilitates catheterization of the urethra and bladder, as it is much more slippery than the substances usually employed: vaseline, oils, fats, and pure glycerine.

### MALE FERN IN HYDATID CYSTS.

Prof. R. Feletti (*La Semaine Médicale*, No. 18, 1894) claims to have obtained favorable results in three cases of hydatid cysts with the administration of the ethereal extract of male fern, in a day's dose of forty to fifty cgms. (six to eight grains); in these patients the cysts which were accessible to palpation rapidly diminished in volume, and in two the tumors completely disappeared under the influence if this drug.

*In charge of the Translator, F. H. Pritchard, A. M., M. D.

### HYSTERIC MUTISM AND ETHERIZATION.

Drs. Fazio and Gioffredi (*La Semaine Médicale*, No. 24, 1894) cured a case of hysteric mutism in a young girl after electricity and hypnotism, both in the waking and sleeping states, had failed. Observing that though while awake she was not able to utter a sound, yet while asleep she had been known to utter articulate syllables and sounds. She was etherized. At the commencement of the procedure she began to cry, talk and complain that they were hurting her, etc. From that instant her disease was cured.

### CITRIC ACID IN DIPHTHERIA.

Dr. H. Laser (*Hospitals-Tidende*, No. 14, 1894) on account of the influence of citric acid on the micro-organism of diphtheria, recommends the following treatment:—Each hour the patient should gargle his throat with a dilute solution of citric acid, which is prepared by adding a teaspoonful of a 5-10 per cent. solution to a glass of water. In small children one may give a teaspoonful every hour or two. In the intervals let the children suck pieces of lemon or drink strong lemonade.

A FRIEND is worth more than a kinsman.—*Ex.*

## EDITORIAL.

### "WORDS FITLY SPOKEN."

Dr. Weir Mitchell delivered the annual address before the American Medico-Psychological Association, at the meeting recently held in this city.

His address was unique in that no time was wasted in laying any flattering unction to the soul. The truth, as the speaker saw it, was set forth in kindly but unmistakable language.

Dr. Mitchell's remarks were directed against the existing systems of management—or mismanagement—of institutions for the insane. But many of his criticisms could be equally well applied to other medical and charitable institutions which are organized on the same general plan.

Without any attempt to present a synopsis of the address, it is interesting to note a few of the just criticisms, the pertinency of which is not limited to asylums for the insane. For instance, he says:

"The mischief begins with the Boards. In some States the appointment and continuance in boards of a physician superintendent is said to be largely a question of politics. Can a man accept such office as a mere bit of party spoil and be fit for it? These Boards have to learn duties and acquire knowledge common enough among neurologists, but what governor comes to us and asks whom he shall appoint? That you depend on such bodies thus made up is a grave evil. Private or endowed asylums are no better off. A managing board has committees and these inspect, I really do not know how often.

"Could not these honest, right-minded gentlemen be brought to know how to do their work with intelligent care?

"What we want is a training school for hospital managers. In appointments I would stand on the scientific record of the physician alone if I had to be limited to one form of knowledge of a candidate.

"Permanent boards acquire the permanent disease of hospital torpor. The ailments of hospitals begin, as a rule, with the governing boards; they do not end there."

Of the special field of neurology as

exhibited in the management of insane asylums—the immediate subject of his criticisms—the speaker concludes that:

"As compared to the splendid advance in surgery and medicine of the eye, and the steady approach to precision all along the ardent line of medical research, the alienist's advance is proportionately little. In your work you have more and more drifted out of relation with the larger life of outside medicine and become a group of physicians who constitute almost a sect apart from our more vitalized existence.

"My fear is that some of you would not change your organization if you could. My belief is that your lives are destructive of energy. You are alone, uncriticized, unquestioned, out of the healthy conflicts and honest rivalries which keep us up to the work. The whole asylum system is in my opinion wrong and has been left to harden into organized shapes which are difficult to reshape. You ought not to live and sleep in your hospitals at all; you ought to be content with the world of sane men.

"In your reports I do not find the urgent repeated demands for obviously needed things. I find too comfortable assurance of satisfaction; too much stress on mere amusement; too little on rewarded work; too many signs of the contented calm born of isolation from the active, living struggle for intellectual light and air in which the best of us live. You hear the regret in every report that patients are not sent soon enough to asylums, as if you had ways of curing which we have not. Upon my word I think asylum life is deadly to many of the insane. You have long, and, as we think, unreasonably fostered the belief that there is some mysterious therapeutic influence to be found behind your walls and locked doors. There lingers a dislike to admit that mechanical restraint should never be used. We think it a question settled past argument. We think, too, of your locked doors and barred windows as being but reminders of that dismal system which we are pleased to think is gone forever. I presume that you have through habit lost the sense of jail and jailor which troubles me when I walk behind one of you and he unlocks door after door. Do you think it is not felt by some of your patients?

"Amid neurologists there is a settled belief that you do not handle your acute cases with sufficient individualization. Once we spoke of asylums with respect; it is not so now. You allow your managers to think you can be farmers, stewards, caterers, measurers, business managers and physicians. It is impossible. Some of you have shed this cumbersome coil of unprofessional business, but still feel overweighted; if so, you need help or are cursed by that slow atrophy to the energizing faculties which is the very malaria of asylum life. Asylum! there is despair in the name.

"When you find a case getting well, and let it go home, do you follow it with most anxious care to avoid relapse? As to the work for the chronic and convalescent, I never yet saw the hospital where all was done that can be done in this direction. I think there must be no effort to make this work pay. The noble object lesson seen at Wernersville, where hundreds of insane practically camped in the open and did work which would amaze many, ought to fill with shame the municipal authorities in this city when they look at our civic insane hospitals where rows of hapless men and women sit watched by attendants, untrained and unintelligent."

The address was delivered by special invitation and although the criticisms were keen and plain stated, the Association showed its appreciation of the sincerity and kindly intent of the speaker by promptly conferring upon him honorary membership in that body.

# ABSTRACTS.

## PRURITUS VULVÆ.

The persistent tickling, itching, and burning of pruritus vulvæ points not only to simple hyperæmic irritation, but to a more marked involvement of the skin-covering and its terminal nerve-bulb filament. Webster, on the basis of microscopic examination of excised portions of skin affected with pruritus, describes a subacute inflammation of the papillary bodies and advanced fibrosis of the nerve-endings, especially marked in the region of the clitoris and the upper portion of the smaller labia. These observations strongly suggest that the disease is in reality an inflammatory neurosis of the vulvar corium.

The severe forms are always associated with local lesion. Even though this is not perceptible to the casual examination, microscopic research will reveal thickening and infiltration.

The pruritus is usually caused by a local disease of the vulva. This region is swarming in germs. It is claimed that in diabetic pruritus the leptothrix and allied organisms occasion the deep skin inflammation, but others of the mycoses, such as that due to the oidium albicans, are often attended with itching.

Webster classifies the cases of pruritus as follows: 1. Endogenous cases. Under this heading are included those in which the blood is altered, as from icterus, chronic nephritis, diabetes mellitus, the waste products circulating in the blood acting upon the terminal nerve-filaments and occasioning itching. Under the same heading would be included the pruritus due to medicines, such as morphine, iodoform, alcohol, etc. Under the endogenous cases would also be classified pruritus caused by varices or congestion of the pudendal veins of the hemorrhoidals or of the pampiniform plexus, such as may come from a weak heart, pregnancy, hemorrhoids, or displacement or overgrowths of the womb. Moreover, certain well-known skin-diseases may occasion vulvar itching. Thus, erythema, herpes, urticaria, and certain forms of eczema may after an acute attack leave permanent alterations of the papillary bodies, which react upon the nerve-endings. Finally, fermentation in the intestinal tract may give rise to products which, absorbed into the blood, may act upon the nerve-endings. The frequent occurrence of constipation in women makes this a causative factor of no little importance.

Under the exogenous cases are classed those due to alteration or increased secretions of the vulvar glands, hyperidrosis, seborrhœa, polyuria with either altered or normal urine, diseased secretion from the vulva, vagina, and uterus, catarrh and suppurative secretions from the rectum, especially discharges from inflamed piles. These secretions are irritative partly from their direct chemical action, partly from their decomposition, irritant products being formed which act directly upon the macerated epithelium, causing erythema, intertrigo, eczema, and in certain cases prurogenous vulvitis. Causes of a parasitic nature are also frequently operative in causing pruritus. Thus, the pediculi, the ascarides, the oxyuris vermicularis, leptothrix, oidium albicans, micrococcus urænæ, gonococcus, smegma bacillus, the ordinary putrefactive bacteria, and the streptococci and staphylococci are said to be, if not the primary and predisposing, at least the secondary exciting causes of itching.

Of mechanical causes, masturbation will perhaps take the first rank; persistent washing and friction, especially when applied by means of sponges which are always unclean, encourages infection. The symptoms are aggravated by the scratching and rubbing occasioned by the symptom. Thermic influences are also operative; thus, there is a winter and summer pruritus.

Usually careful examination as to etiology indicates the most promising method of cure. Thus, where the disease is due to parasites, lack of cleanliness, to drugs, to decomposing discharges, to venous congestion, etc., the efficient treatment is obviously removal of the cause of the diseased local conditions. In those cases dependent upon visceral alteration, the local treatment must be subordinate to attention to the general condition. Thus, the appropriate regimen must be indicated in each instance in accordance with whether the patient be diabetic, jaundiced,

subject to Bright's disease, or suffering from venous congestion incident to heart weakness. The gouty or rheumatic diathesis must be properly treated.

Antiseptics as local applications are most useful. These are generally combined with astringents and with local anæsthetics.

Among the favorite methods of treatment are prolonged hot baths, followed by hot douches. These douches should be antiseptic and anæsthetic; thus, solutions of carbolic acid as hot as can be borne are of special service. It is noteworthy that the area affected by pruritus can stand a much stronger solution than can be used upon a healthy surface; thus, irrigations of 1 to 40 or 1 to 20 may be made. Bichloride is also serviceable, but the anæsthetic effect of the carbolic acid is lacking in this drug. A favorite prescription of D. Hayes Agnew, recommended as almost a specific in pruritus ani, is:

℞ Sulphate of zinc,
Alum, of each, equal parts.

To be mixed and heated until the water of crystallization is driven off. A drachm of this is added to an ounce of water and is applied locally. At times the carbolic lotion proves too irritating; then a simple astringent may be employed, such as fluid extract of hydrastis, 1 drachm to 1 pint, or hamamelis, fifty per cent., or even full strength. After prolonged douching, either with hot solutions of hydrastis or hamamelis, the parts may be bathed with a prescription made up of,—

| | | |
|---|---|---|
| ℞ | Menthol | gr. i. |
| | Cocoaine | gr. xxxvi. |
| | Alcohol | |
| | Water, of each | ʒi. |

Or an ointment may be applied made up of,—

| | | |
|---|---|---|
| ℞ | Menthol | ʒi. |
| | Simple cerate | ʒii. |
| | Oil of sweet almonds | ʒi. |
| | Carbolic acid | ʒi. |
| | Pulv. zinc oxide | ʒii. |

Or,

| | | |
|---|---|---|
| ℞ | Menthol | ʒi. |
| | Carbolic acid | ʒi. |
| | Lanolin | ʒii. |
| | Pulv. zinc oxide | ʒii. |
| | Unguent. zinc oxide | ʒi. |

Or a strong lotion of carbolic acid may be dabbed on, according to the following formula:

| | | |
|---|---|---|
| ℞ | Carbolic acid | ʒii. |
| | Glycerin | |
| | Water, of each | ʒix. |

Painting the vulva with glycerin mixed with a ten-per-cent. solution of chloroform and glycerin, with a ten-per-cent. solution of carbolic acid and glycerin and alcohol, or a solution of nitrate of silver of similar strength, is sometimes serviceable.

Madden recommends oleate of chloral painted over the parts. This is a compound formed of equal parts of camphor, chloral, and oleic acid. Where the disease is due to irritating uterine or vaginal discharges, he recommends the introduction of a tampon of cotton-wool loaded with equal parts of finely-powdered alum and sugar, and carried within the vulvar orifice. He holds that in his dispensary practice black wash is regarded as a most generally useful as well as a very cheap available application in such cases.

Goodell recommends a strong emulsion of iodoform and glycerin (ten to twenty per cent.).

Skene commends vaginal douches of acetate of lead, and dusts subnitrate of bismuth on the labiæ to prevent friction. This he holds is especially serviceable in diabetic cases. In the cases in which the etiology was obscure, he states that the remedies which have given him the best results are bichloride of mercury in emulsion of bitter almonds, one grain to the ounce, applied to the parts affected twice a day; a powder composed of one grain of morphine to two grains of chalk, applied night and morning; equal parts of tincture of opium, iodine, and aconite, and eight per cent. of carbolic acid, applied once a day; and ethereal solution of iodoform, applied by means of an atomizer. In some cases application of equal parts of carbolic acid and tincture of iodine relieved permanently. This was used in one case by means of an atomizer, the spray being driven under high air-pressure. An acute inflammation followed, but after the patient recovered from this the pruritus did not return. In certain cases, in spite of every local and general treatment, disease persists and renders life almost unendurable. Under such circumstances there remains surgical intervention.

Carrard reported the first case of surgical intervention. The clitoris was the part affected; its removal was followed by cure.

Schroeder carefully localized the points of itching, and then removed them by section in five cases. In one of these cases the disease was complicated by carcinoma. In another, in addition to excision of the diseased vulvar surface, a ring of skin was

taken from around the anus. In the three remaining cases the disease was purely pruritus vulvæ. In the first, a small area was removed from the right labium majus; in the second, the right labium majus was excised, and following this several lesser operations were performed; in the third, in which both the clitoris and lower lips were involved, the operation was more extensive. The women all recovered. The operator stated that intervention should only be attempted when the itching was localized, and cautions against attempting to cure a widely diffused pruritus by the knife.

Küstner also reports three successful cases.

Martin reports four, and a number of other operators state that the results were successful.

Sänger (*Centralblatt für Gynäkologie*, No. 7, 1894) contributes the full notes of two cases, both entirely successful.

He closes his thesis with the following statement:

The partial or total extirpation of the vulva is an entirely legitimate operation in cases of chronic pruriginous vulvitis not curable by other means. In younger persons the surgeon should be content with partial operation. In aged persons, when the disease is widely extended, the whole vulva, including the glans clitoris, should be entirely extirpated and the wound closed by plastic operation.—*Therapeutic Gazette.*

## THE ACTION OF LIGHT UPON THE DIPHTHERIA BACILLUS.

A recent number of the *Archives de Medicine Experimentale* contains an article by Dr. Ledoux-Lebard, detailing the results of experiments undertaken by the author for the purpose of ascertaining to what extent sunlight is effective as a means of destroying the microbes of diphtheria. The special purpose of the experiments was to determine whether the influence of diffused light is destructive of germs as well as the direct rays of the sun, as shown by Roux and Yersin. The conclusions to which he arrived are as follows:

1. The action of diffused light does not prevent the development of cultures of the diphtheria germ, either at a tempera ture of 95° or at ordinary temperatures. The direct rays of the sun arrest the development of the germs, and sterilize the culture medium in a few days. Diffused light has no bactericide power in relation to bacilli in neutralized bouillon, but has a marked bactericide power in relation to diphtheria bacilli in distilled water.

2. Diffused light kills dry cultures of diphtheria spread in thin layers, in less than two days (twenty-four hours' exposure to light).

3. The direct light of the sun acts in the same manner as diffused light, but with greater rapidity.

4. The bactericide power of light in relation to the diphtheria bacillus is due almost entirely to the most highly refracted rays of the spectrum.

5. The less refracted rays of the spectrum have little or no bactericide power.

6. Light, by virtue of its bactericide power, sterilizes in less than two days the bacilli of diphtheria, either moist or dry, and hence is a prophylactic agent against diphtheria.

7. In diphtheritic membranes exposed to the light, many of the bacilli are reached only by the light after it has lost a part of its intensity, and hence retain their vitality and virulence for a long time.

8. Light may be utilized in the disinfection of places contaminated by diphtheria.

The persistence of the virulence of the germs of diphtheria is well known, but a careful study of the classical examples of extreme persistence of this virulence shows that in the majority of cases, the contaminated objects had remained a long time protected from the light. In one case, for example, a brush which had been used for making applications to the false membrane of a child, communicated diphtheria to the father four years afterward, having been, in the meantime, wrapped in paper and placed in a drawer.

In other cases the means of contamination has been clothing which had been worn by a diphtheritic patient, and which had been protected from the light in a chest or closet.—*Modern Med.*

# SOCIETY REPORTS.

## PROCEEDINGS OF THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

*Meeting of 1894.*

[STENOGRAPHICALLY REPORTED BY L. C. ALEXANDER.]

The Forty-fourth Annual Session of the Medical Society of the State of Pennsylvania, was held in Philadelphia, May 15th to 18th, inclusive.

### TUESDAY MORNING.

The session was called to order by the President, Dr. H. G. McGormick, of Williamsport, at 10 o'clock.

Prayer was offered by Rev. A. B. Philput.

An address of welcome was made by Hon. Edwin S. Stuart, Mayor of Philadelphia, as follows: "Gentlemen, and Members of the State Medical Society: I was some time ago informed by a gentleman representing a large convention here, that one of the necessary evils of meeting in Philadelphia is an address of welcome by the Mayor, so I will not detain you long. I am glad you will meet in this city, for Philadelphia has been closely allied with the medical profession from its earliest days. As you all know the first hospital for the treatment of the sick was inaugurated in Pennsylvania on the application of Benjamin Franklin, and was erected in Philadelphia. From that time until now it has been doing excellent work.

"The first medical school, and the first school of anatomy were also inaugurated and located in Philadelphia, and for that it is a good reason why your society should meet here. From the time of the founding of these schools, the city has always maintained a creditable position. Philadelphia some time ago was made a place containing many colleges which were a disgrace to the city. They have been wiped out, and I hope never to see them again in Philadelphia, nor in the United States.

"I will not detain you longer, but, in the name of the people of Philadelphia, I extend to you a sincere and hearty welcome. And on behalf of your professional brethren of Philadelphia I also extend to you a hearty welcome, and I hope that the deliberations of your society will be of advantage to the medical profession not only in Philadelphia, but in America generally."

The address of the Mayor was followed by one of welcome by Dr. E. E. Montgomery, Chairman of the Committee of Arrangements. Dr. Montgomery spoke as follows:

"Gentlemen—As His Honor, the Mayor, has touched upon the medical side, it is my part to touch upon the political side. I welcome you to a new Philadelphia. You have seen in the papers the many measures that are being considered to add to the prosperity of this city. These measures are largely due to the gentleman who has just spoken, and his memory will long live in the heart of Philadelphia. We have quite a large programme to be gone over during this meeting, and added to this there have been a number of entertainments provided. In addition also, Philadelphia, with her usual hospitality, will throw open the doors of her hospitals, that the profession may see the latest methods of work. Dr. Roberts invites the delegates to his clinic, on Friday, at the Woman's Hospital. I will not detain you longer. You are welcome to Philadelphia, and we propose to make your stay as pleasant as possible."

Dr. William B. Atkinson, the Secretary, reported that there were fifty County Medical Societies in good standing, and that the State Society at present numbers twenty-five hundred members.

Dr. G. B. Dunmire, the Treasurer, reported the total receipts for 1894 as $4,122.24, and an expenditure of $2,423.45.

An invitation was extended to all members of the Philadelphia County Medical Society to attend the sessions of the State Medical Society.

The Committee on Publication reported that 2,500 copies, containing 300 pages of the report of the Transactions of the Medical Society for 1893, had been printed. Fifty-six of these copies had been distributed among the State Boards of Health, medical schools, and hospitals.

The report of the Committee on Scientific Business, Dr. C. W. Dulles, Chairman, was read and adopted.

Dr. J. A. Lippincott, of Pittsburgh, read the report of the Committee on the Prevention of Contagious Diseases of the Eye in Asylums.

Dr. John B. Roberts, of Philadelphia, Chairman of the Committe on Legislation, read the report of that committee, which was adopted.

The Society took up as new business, a series of resolutions referred by the Philadelphia County Medical Society, to the effect that the Trustees of the Journal of the

American Medical Association, in disobedience of the resolution of the Association adopted at the Detroit meeting, persist in publishing advertisements of secret nostrums.

The discussion of this matter was made a special order of business for Wednesday morning, following the paper of Dr. S. Solis-Cohen, "Should the Journal of the American Medical Association be used to Promote Quackery?"

Dr. I. C. Gable, of York, presented a resolution that, since the medical law of the State has been violated by the illegal registration of physicians, a committee of seven should be appointed to report on Wednesday, regarding the appointment of Inspectors, whose duty it shall be to aid the State Board of Medical Examiners in preventing illegal registration.

A preamble and resolution was presented by Dr. George M. Gould, of Philadelphia: "As it is admitted by all physicians that one-half of the blindness of the world is due to the disease called ophthalmia neonatorum, and as it is well known that treatment by a physician, if he is called sufficiently early in the course of the disease, always results in preventing blindness;—

"*Resolved*, That in the opinion of the Medical Society of the State of Pennsylvania, it is of the most vital importance to the welfare and happiness of the community and to the good name of the State of Pennsylvania, that the law recommended by the Committee of the Section on Ophthalmology of the American Medical Association, shall be adopted by the legislature of the State."

The law already adopted by five States reads: "Should both eyes of an infant become inflamed, or swollen, or reddened, at any time within two weeks of its birth, it shall be the duty of the midwife or nurse having charge of the infant to report in writing within six hours to the health officer, or to some legally qualified physician in the city or district in which the infant lives. The penalty for failure to comply with the law is made fine, or imprisonment not to exceed six months, or both.

The resolution was adopted and a committee appointed to present it to the State Legislature.

A resolution, presented by Dr. S. Solis-Cohen, that the Society is opposed to any revision of the code of ethics, was adopted.

---

TUESDAY AFTERNOON.

The session was confined almost entirely to scientific business.

With reference to the proposed action of Congress to reduce the number of medical officers of the United States Army, a resolution, presented by Dr. Keyser, of Philadelphia, expressing the disapprobation of the Society, was adopted.

The address in Surgery was read by Dr. G. D. Nutt, of Williamsport.

Dr. E. La Place, of Philadelphia, read a paper on "The Radical Cure of Hernia." Dr. J. C. McAllister, of Driftwood, read an article on "Puerperal Eclampsia and its Treatment, Chiefly by the Hypodermic use of Veratrum Viride." "Modification of Pirogoff's Amputation" was the subject of Dr. F. Lemoyne, of Pittsburgh. Dr. J. V. Shoemaker, Philadelphia, gave some interesting "Clinical Observations upon Diseases of the Skin."

"Section of the Tendo-Achillis in Certain Fractures and Dislocations of the Lower Extremity," Dr. Thomas S. K. Morton, Philadelphia, was read by title. Dr. John B. Deaver read a paper on "Chronic and Recurrent Appendicitis." Dr. Orville Horwitz's paper was on "Treatment of Stricture of the Urethra." "Cramming in Medical Schools" was the title of Dr. O. H. Allis' paper. A number of papers were received and read by title, on account of the length of the session.

---

WEDNESDAY MORNING.

The meeting was called to order at 9.30 A. M.

The report of the Committee on Nominations was announced as follows: *President*, John B. Roberts, of Philadelphia; *First Vice-President*, Dr. S. C. Stewart, of Clearfield county; *Second Vice-President*, Dr. J. A. Lippincott, of Allegheny county; *Third Vice-President*, Dr. J. H. Wilson, of Beaver county; *Fourth Vice-President*, Dr. R. Armstrong, of Clinton county; *Secretary*, Dr. William B. Atkinson of Philadelphia; *Assistant Secretary*, Dr. H. G. Chritzman, of Franklin county; *Treasurer*, Dr. G. B. Dunmire, Philadelphia.

*Members of the Judicial Council:* Dr. C. L. Stevens, Bradford; Dr. I. C. Gable, York; Dr. W. T. Bishop, Dauphin.

*Delegates to the American Medical Association:* Drs. J. K. Weaver, Montgomery; J. H. Vastine, Susquehanna; L. B. Kline, Columbia; G. H. Kirwin, Luzerne; J. F. Ross, Clarion; J. W. Hughes, Westmoreland; H. G. Chritzman, Franklin; William Anderson. Indiana; J. M. Beyer, Jefferson; S. Solis-Cohen, E. E. Montgomery and Edward Jackson, Philadelphia; I. Davis, Montgomery; D. M. Weidman, Berks; J. L. Ziegler, Lancaster; J. P. Simpson, Beaver; J. B. McAllister, Dauphin; S. M. Woodburn, Bradford; J. P. Getter, Mifflin; R. B. Hammer, Westmoreland; W. G. Gifford, Chester, and J. C. McAllister, Montgomery.

*Delegates to New York State Medical Society*, Dr. I. W. Groff, Montgomery; *New Jersey Society*: Dr. C. A. Rahter, Dauphin; *Mary-*

*land Society*, Drs. A. C. Wentz, York, and P. R. Koons, Cumberland.

Dr. William S. Foster, of Pittsburgh, read the Address in Medicine.

Dr. S. Solis-Cohen, in his remarks on "Should the Journal of the American Medical Association be used to Promote Quackery?" said:

"The question which I desire to present is of such great importance, the issues involved are so clearly defined, and the duty of this Society so obvious that I feel an elaborate argument would be out of place; that it would hinder rather than help the understanding of the subject, and I shall therefore content myself with a brief statement of facts. If I should make any error in the presentation of the facts I earnestly beg that I shall be corrected, as I desire to be unjust to no one. I would like to say also, that although the attempt has been made in certain quarters to convert this question into a personal question, it is not personal in any sense whatever.

"The trustees of the *American Medical Association Journal*, have committed to them by the American Medical Association, a deed of trust, and we find upon the pages of the Journal of the American Medical Association, advertisements of quack secret nostrums. Every reputable physician will say, 'Surely, the Trustees will not admit of such advertisements were they fraudulent,' and I believe many have been led to prescribe under the auspices of the Trustees. I am not criticising their personal conduct. I believe that official conduct would be a proper subject of public criticism.

"At the meeting of the Medical Society of Pennsylvania, held at Harrisburg, on May 18th, 1892, resolutions were adopted, disapproving of the practice of inserting advertisements of secret medicines in the medical journals. These resolutions were transmitted to the medical meeting at Detroit. In a meeting, crowded in anticipation of the subject, Dr. C. H. Thomas arose, and presented a resolution calling the attention of the Trustees to the violation. That resolution was unanimously adopted. It was received with such applause that no one dared to stand in the presence of his Fellows, for quackery! The Trustees then passed a resolution that any preparation, of which the formula could be communicated to their members, should be published—making all of us partners in this infamous business. I trust that the Medical Society of the State of Pennsylvania shall not be made a partner in the secret nostrum business, and I therefore ask that the Association once more record itself upon this question, and not only to enforce the resolution, but to instruct its delegates to take such action at San Francisco that will secure as Trustees of the Journal of the American Medical Association, men who will obey the resolutions of the Association."

Following Dr. Cohen's remarks, a series of resolutions, forwarded to the State Medical Society by the Philadelphia County Medical Society, condemnatory of the secret nostrum advertisements, and advocating their exclusion from the Journal of the American Medical Association, were discussed. [These resolutions were printed when adopted by the Philadelphia County Medical Society.]

Dr. C. H. Thomas, of Philadelphia, said: "I agree with all that Dr. Cohen has said. I do not see the face of one who I believe takes exception to what he has said. There are men here who were in Washington at the time of the organization and establishment of the Journal of the American Medical Association. Some of us remember that it was put forward as one of the best reasons for establishing that paper, that we would be sure of having an improved standard ethically. We have been treated to the singular spectacle of that journal going further than any other, in the practice of lining its pockets and helping to support itself by the contributions from quack medicines. We become partners under these circumstances, and every man must take shame to himself, unless he clear himself of this state of affairs."

A resolution was adopted that the Trustees of the Journal of the American Medical Association be informed that the American Medical Association prefers to have the publication of the Journal discontinued, if the money from quack advertisements is necessary for its maintenance. It was ordered that a copy of the resolutions of the Philadelphia County Medical Society be sent to each Trustee of the Journal.

Regarding illegal registration, resolutions were adopted that an accurate copy of registrations under the present law, on and since the first day of last March, and quarterly thereafter, in counties where there are no county medical societies, be forwarded to the Secretary of the State Board of Examiners, by the Secretary of each county society; and that where there are no county medical societies, a member living in the locality shall be appointed by the President to procure such list. Should such list not be sent, the State Board of Examiners shall be required to obtain the same. With the view of preventing disregard of the law, the Society appropriated $500 of its funds.

A resolution was adopted setting forth the advantages of an Epileptic colony, to be established for epileptics dependent upon the Commonwealth. It was ordered that copies of the resolution be sent to the Governor, the Speaker of the House, the President of the Senate, and to the President of the State Board of Charities.

Dr. Hildegarde H. Longsdorf, of Carlisle, read a paper entitled, "Christian Science in its Relation to the Medical Profession."

Papers were read by Dr. B. H. Detwiler, of Williamsport, and Dr. Charles Hermon Thomas, of Philadelphia. Others were read by title.

WEDNESDAY AFTERNOON.

At the opening of the session it was announced by Dr. H. G. McCormick, President of the State Board of Examiners, that the first examination under the recent law for license to practice in Pennsylvania, would be held simultaneously in Philadelphia and Pittsburgh, on June 11th. All applicants to be given the same questions.

Touching the appropriation for the support of the Library of the Surgeon-General's Office, at Washington, a resolution was passed urging Congress not to reduce the amount.

THURSDAY MORNING.

Under the head of unfinished business, Dr. S. S. Towler was appointed a member of the Committee on Scientific Business. Drs. Edward Jackson, H. F. Hansell, and J. A. Lippincott were appointed the Committee on Dr. Gould's resolution, by the President, Dr. McCormick.

A resolution was adopted that the Judicial Council of the American Medical Association be requested to take such action as necessary, in regard to the Trustees of the Journal of the American Medical Association, to sustain the integity of the Association and enforce the provisions of its code.

A resolution was adopted requesting the members of the Medical Council of Pennsylvania, and the State Board of Medical Examiners, not to use in connection with the Examining Board representing this Society, any sectarian title.

A resolution was adopted expressing the Society's approval of the establishment of a Bureau of Public Health, believing that the welfare of the country would be benefited; and asking that the passage of the bill be aided by the earnest efforts of our State representatives. It was decided to send to each Senator and Member of the House of Representatives at Washington a copy of the resolution.

An amendment to the By-Laws, providing that it shall be the duty of the Committee on Scientific Business to have the programme arranged and distributed within thirty days of the holding of each meeting, was offered by Dr. C. W. Dulles, of Philadelphia.

Papers were read as follows: The Address in Hygiene, by Dr. J. H. Wilson, of Beaver. Dr. A. M. Cooper spoke of "Psychical Phases in Married Tubercular Folk." "Prophylaxis in the Treatment of Tuberculosis," was the subject of a paper by Dr. Lawrence F. Flick. Dr. Flick's paper, and those of Drs. Hamilton, Thomas J. Mays, and others, bearing upon Tuberculosis, were discussed at length by Drs. S. Solis-Cohen, W. E. Hughes, J. C. Wilson, J. Solis-Cohen, J. M. Anders, and others. Dr. J. Solis-Cohen mentioned the desirability of mare's milk in the treatment of consumptives, from the fact that a horse was never known to have tuberculosis, and from the satisfactory results obtained from its use in the Home for Consumptives at Chestnut Hill.

THURSDAY AFTERNOON.

The Committee on Legislation was announced.

The President-elect, Dr. John B. Roberts, of Philadelphia, was introduced by Dr. McCormick. He took the chair and announced the appointments for the Annual Addresses of next year, as follows: Address in Medicine, Dr. I. C. Gable, of York county. Address in Obstetrics, Dr. W. B. Ulrich, of Delaware county. Address in Surgery, Dr. C. L. Stevens, of Bradford county. Address in Hygiene, Dr. Hildegarde H. Longsdorf, of Cumberland county. Address in Mental Diseases, Dr. F. X. Dercum, of Philadelphia county. Address in Otology, Dr. L. H. Taylor, of Luzerne county.

# THE LIBRARY TABLE.

## BOOK REVIEWS.

*A System of Genito-Urinary Diseases, Syphilology and Dermatology*, by various authors. Edited by Prince A. Morrow, A.M., M.D., Clinical Professor of Genito-Urinary Diseases, formerly Lecturer on Dermatology in the University of the City of New York; Surgeon to Charity Hospital, etc. Illustrated. In three volumes. Vol. II. Syphilology. New York: D. Appleton & Co., 1893.

As we have said in reviewing the first volume of the System, the articles represent the latest thought on the various subjects; and the men who write them, instead of scarcely being heard of till the appearance of the work, are men who stand in the fore front of the medical profession in the lines in which they have chosen their specialty. The editor states in his preface that "With the view of meeting the wants of the general practitioner, the subjects of diagnosis and treatment have received more consideration than is usually allotted to them in works of this class." The editor's promise has been carried out by the contributors—a point that we feel sure the general practitioner will appreciate.

The section on History, Geographical Distribution and General Pathological Anatomy of Syphilis is contributed by James Nevins Hyde, M.D. The author has long been occupied in researches as to the existence of syphilis in prehistoric times, especially among the aborigines of this continent, and in this article are given the fruits of his labors.

The Etiology of Syphilis is discussed by John A. Fordyce, M. D. From analogy with tuberculosis, leprosy, glanders, etc., the author concludes that syphilis is due to some micro-organism, though it cannot be proven with certainty till the discovery of the germ. After reviewing the failures in experimental inoculation of animals, the author concludes: "The future work in the etiology of syphilis must be directed to devising some staining method which will reveal the constant presence of the micro-organism in the products of the disease, and a culture medium upon which it will grow. When these conditions are complied with, opportunities may be afforded for inoculations which will conclusively demonstrate its etiological relationship to the disease."

The article on the "Modes of Infection in Syphilis" is from the pen of L.Duncan Bulkley, M.D. The article is intensely interesting, going into, as it does, the question of the innocent inoculation with the disease, as well as by the more usual channels—direct contact, mediate infection, hereditary transmission, and maternal infection. The author states that it is not believed that the normal secretions—milk, saliva, etc.—can communicate the disease, except when they act as the carriers of a pathological secretion from a syphilitic lesion. The article treats also of the acquirement of the disease through the daily duties of industrial and professional life, as instanced by the inoculation of glass-blowers through the blow-pipe and the physician in his maternity and gynæcological work. It is interesting to note what he says in regard to vaccination: "It is not believed that the absolutely pure vaccine lymph of the eighth day can communicate the disease, but that there must be an admixture of blood, pus, or some other element from the syphilitic person, in addition to the pure lymph. This may occur from the serum which oozes from the vesicle after the first portion of the clear lymph peculiar to vaccinia has been taken, when the surface is urged by pressure to yield more than the normal amount." In regard to razor wounds he says, "It is highly improbable that the razor plays any part in the event, other than causing the abrasion through which the syphilitic virus gains entrance." Indeed, he is rather inclined to doubt that the towels, soap and brush are the carriers of the contagion, but rather attributes the infection to the act of kissing, etc., at any house of prostitution that the subject may visit subsequent to the shaving. In some instances the infection undoubtedly took place from court-plaster which has been furnished and applied by a friend who used saliva to moisten it. The author is inclined to regard the infection of the woman through the semen possible—a theory that has been strongly denied by some—though he thinks it may also be accounted for by the view that a pregnancy of only a week or two duration has resulted from the union and that the woman has been infected through the ovum. We are sorry to note that the author has treated the subject of syphilis insontium, or syphilis innocently inquired, in a very few pages, referring the reader to his work on that particular subject.

The chapter on "Primary Syphilis" is written by Edward Bennet Bronson, M.D. The author would limit the term chancre to the non-infecting sore or the chancroid, designating the infecting or syphilitic sore by the term initial lesion of syphilis. This is on the basis of the meaning of the word chancre—destructive ulceration—which property resides more in the non-infecting than in the infecting sore.

Constitutional Syphilis has been assigned by the editor to Joseph Zeisler, M.D., while the editor himself, Dr. Morrow, describes Syphilis of the Skin, and Samuel Alexander writes of Syphilis of the Appendages of the Skin—the Hair and the Skin. Syphilis of the Mucous Membranes of the Mouth and Tongue is described by Charles W. Allen, M.D. Syphilis of the Joints, Muscles, Bursæ, Tendons and Aponeuroses is allotted to Frank Hartley, M.D., and to W. R. Townsend, M.D., has been given the chapter on Syphilitic Affections of the Bones.

The "Diagnosis and Prognosis of Syphilis" is the subject of an interesting discussion by Hermann G. Klotz, M.D. The author takes the common-sense view that the administration of specific treatment should not be begun

till the outbreak of such symptoms as make the diagnosis certain—in other words, until the appearance of the secondary lesions. The practitioner who sees much of venereal disease will often meet cases where he may feel positive that the sore is an infecting one and yet which will be followed by no symptoms of syphilis, even under no treatment whatever. In such a case it would have added immensely to the uncertainties of the case had the patient been put on antisyphilitic treatment so soon as the sore appeared, and neither physician or patient could ever have been sure that the sore was or was not an infecting one. The exception to this rule is where the seat of the lesions or their grave character demand immediate treatment even though there be a doubt as to their positive nature. The author affirms that syphilis is curable, this opinion being grounded on those instances where reinfection has taken place, since it is a well-known law that a syphilitic cannot be inoculated with the disease. The author affirms also that while the primary and secondary stages of the disease are constant, the tertiary stage is a much less constant consequence of the infection than the secondary; a large majority of the patients doubtedly escaping. In regard to the commonly accepted idea that extra-genital sores are more regularly followed by serious symptoms, the author states that his experience does not warrant any such conclusion. The prognosis of the disease to a certain extent depends largely on the habits of life of the individual, and the author warns against the use of tobacco by syphilitics on the ground that the lesions of the mouth are aggravated by its use. Alcohol is also to be forbidden, though it is a question whether it should be taken from a patient accustomed to its daily use. In such cases it would seem better to continue it in moderate amount simply for its supporting effect.

"The Treatment of Syphilis" is thoroughly described by Dr. J. William White in an able article. The author urges that every adult citizen should be made aware of the danger to himself and his family from syphilis, and every syphilitic should be told the serious character of the disease he is suffering from, and be made to realize that, except after certain intervals and under proper restrictions, his marriage is an outrage to the woman he professes to love, and a crime against society. The author also reviews the results in foreign countries of the police regulation of prostitution and the registration system in use in Paris, and recommends that prostitution be under state supervision. In this article are considered the advantages and disadvantages of the abortive treatment of the disease, and the author decides that the administration of mercury during the existence of the primary sore, unaccompanied by general symptoms, for the purpose of suppressing or aborting syphilis, is not justifyable, unless by confrontation the diagnosis can be confirmed, or unless there are urgent and unquestionable reasons for securing rapid cicatrization of the chancre. He considers the chances of preventing constitutional syphilis by cauterization or excision of the sore very slight, though it may be proper to employ such measures in a sore following intercourse with a person known to have syphilis. He regards the essential point in the treatment of syphilis to be the administration, during a sufficiently long period, of the largest dose of mercury which can be taken and absorbed without prejudice to the general health. In opposition to many, he considers the use of opium in conjunction with mercurials to be an unsafe practice, and especially does he oppose the use of Dover's powder advocated by Hutchinson. When it is necessary to counteract the griping and diarrhœa he prefers to prescribe paragoric, telling the patient to take only the smallest amount which will overcome the irritant effects of the mercury. His objection to the opium is that the secretions both of the skin and alimentary tract are lessened, and in this way the general health of the patient may suffer. Further than this there is nothing new in the article which describes the various methods of administering mercury, and also the so-called "Mixed Treatment." The hypodermic method is also carefully reviewed by the author, who rightly condemns it. He states his belief that "on the whole, while the final outcome of the experience of the last few years will doubtless be for the advantage of science and the extension of our therapeutic methods, the information thus acquired will be at the expense of many patients who will suffer from the direct consequences of the method itself, or succumb to the ultimate developments of insufficiently treated syphilis." In another portion of the article he asserts that "The hypodermic treatment of syphilis has not as yet shown results which warrant its adoption as a routine method to the exclusion of or in preference to other methods, but, on the contrary, has some apparently insuperable disadvantages and even dangers which render it improbable that it will ever be so adopted."

The earliest period at which a syphilitic may marry is placed by the author at four years.

The important subject of "Syphilis in Relation to Public Health" is placed in the hands of Samuel Treat Armstrong, M.D.

The chapter on "Chancroid" is written by Edward Martin, M.D. In it he still advises the treatment of the sore by cauterization. Many will question the advisability of this as the impression seems to be gaining ground in the minds of the profession that any irritation of the sore tends to bring about the complication of suppurative adenitis of the glands of the groin.

The want of space forbids more than the simple notice of the authors of the various other chapters of the work: "Visceral Syphilis" is described by W. T. Councilman. "Syphilitic Affections of the Rectum and Anus" by James P. Tuttle, M.D. "Syphilis of the Genito-Urinary System, Male and Female," by Eugene Fuller, M.D. Dr. B. Sachs contributes the article on "Syphilis of the Nervous System," while "Hereditary Syph-

ilis of the Nervous System" is from the pen of William N. Bullard, M.D.

"Syphilis of the Eye and its Appendages," both acquired and hereditary, is discussed by Dr. Charles Stedman Bull; and "Syphilis of the Ear" by Dr. J. Orne Green. The chapter on Hereditary Syphilis is contributed by F. R. Sturgis, M.D.

As is almost always the case in such works there is some little overlapping of the articles, but as a whole the work is singularly free from this fault. The editor is truly to be congratulated on his work. The presswork is particularly fine, and the publishers have evidently spared no expense to make the book attractive. The plates and illustrations are for the most part from photographs, and as a rule are original and prepared expressly for the book. Four of the plates are reproduced by photography and lithography combined, and the result is startlingly beautiful. Altogether the work stands a magnificent monument to American learning and art. It is not too complex to be of use to the general practitioner, nor too elementary for the specialist. To both alike it will prove of great value. The remaining volume of the series will be devoted to dermatology.

E. J. M.

---

*Pain in its Neuro-Pathological, Diagnostic, Medico-Legal and Neuro-Therapeutic Relations*, by J. Leonard Corning, A.M., M.D., Fellow of the New York Academy of Medicine, etc. Pages 322, with 21 cuts in the text.

This book gives brief accounts of various diseases in which pain is a symptom of more or less prominence, and usually gives the means the author employs for its relief.

The principal novelty in the work appears under the head of Therapeutics—the author's method of applying analgesics by the galvanic battery; his application of drugs directly to deeply-seated nerves, the cauda equina, etc., by a long hypodermic needle; and an elaborate apparatus for (practically) applying dry cups to the jugulars, by applying compressed air to the entire body, and then bringing the skin over the jugulars in contact with the outer air.

---

THE TEXAS SANITARIAN

for April. Dr. Francis H. Atkins, of Las Vegas, New Mexico, writes about

**Pneumonia, especially Broncho-pneumonia, in New Mexico.**

This author thinks croupous pneumonia pretty closely confined to a belt of country extending north and south two or three hundred miles, along a line drawn from Cape Hatteras due west to the great plains. Men who live outside of this belt and yet claim to treat large numbers of cases of pneumonia, the author thinks, probably include in their lists a large proportion of broncho-pneumonia. He gives the differential diagnosis: a lobe uniformly affected in the one case, with a sudden onset from perfect health to a great rigor, with high fever, pain, hurried respiration, rusty sputum, etc. On the other hand, a case where typhoid fever, influenza, or some other depressing disease is followed by a cough, slight rise in temperature, dullness in spots of varying size throughout one or both lungs, most easily found posteriorly, varying in degree, and perhaps, the author says, in position from day to day.

Most authorities find the greater number of cases of broncho-pneumonia in young children. This has not been the experience in Las Vegas; but the cases which resulted seriously usually showed plain symptoms of tubercle, and were probably either tuberculous at the outset or caused the lungs to take on a condition favorable for the development of the more serious disease.

So far as treatment is concerned, the author believes in full doses of calomel at the onset, and the use of cotton, covered by oiled silk jacket, muriate of ammonia with ipecac as an expectorant. As cardiac and respiratory stimulants the author uses strychnia, nitroglycerine, belladonna, etc., sometimes finding caffeine very useful, sometimes very badly borne. Fresh air is, of course, very important.

Other papers in this issue are "Erysipelas," by Dr. N. B. Kennedy, a study of *Chaparro Amargosa*, by J. L. Pulegnat, Jr., Ph.G., and a letter from Dr. Arthur S. Wolff, in regard to the same drug.

---

THE BROOKLYN MEDICAL JOURNAL

for May. Dr. E. A. Day has a paper on

**Recto-Colonic Alimentation.**

After concisely reviewing the steps his predecessors have taken in the direction of feeding patients through the rectum, he points out the requisites for a useful food for use in this manner: It must be a nutrient fluid, sterile, bland, absorbable, easily obtained and readily prepared. Failure to observe these points has been one reason that it has been heretofore impossible to support the life of a patient, by rectal feeding alone, for more than a few weeks at the outside. If the preparation used is not bland and sterile, we have, in a varying length of time, an attack of diarrhœa which prevents any further use of this means, and, if all of the injection is not absorbed, the residue creates an irritation which has the same result.

Another point brought forward is that the rectum is not suited for any purpose but that of excretion, and the mere presence of anything in the passage sets up involuntary ex-

pulsive movements; the colon, however, is quite different—it will readily contain several quarts of fluid, and in a reasonable time this will be absorbed.

Acting on the principles mentioned, the author makes use of a firm rubber tube about thirty inches long, fitted with a funnel which he fills with liquid at about the temperature of the body, and elevates enough to secure steady flow.

The tube need be introduced only from three to six inches within the sphincter ani, and, to show how much might be retained when given in this way, one case was mentioned which received and retained an average of eighteen ounces of fluid every hour for twenty-nine hours. At the end of this period the bowels moved freely, and an abundant excretion of urine occurred.

The preparations which Dr. Day is in the habit of using are the Liquid Peptonoids of the Arlington Company, and Panopepton of Fairchild Bros. He insists on the necessity of using from two to six ounces of sterilized water in every enema, and the use of a free enema some hours before an injection is given —even if it seem impossible that any residue can be in the bowels.

The length of time for which this method may be employed was well shown in a case, cited at some length, in which for a year, except during a few short intervals, it had to be mainly depended on to sustain life.

Other articles are "Methods of Drainage and a New Aseptic Drainage Tube," by Dr. Joel W. Hyde, and "Small-pox in Brooklyn," by Dr. F. A. Jewett.

---

THE AMERICAN JOURNAL OF OBSTETRICS

for May. Dr. D. Berry Hart, of Edinburgh, contributes an article on

**The Extraperitoneal Form of Extra-uterine Gestation.**

While there is no doubt that the fetus is often intraperitoneal, this is no positive proof that the gestation is intraperitoneal. The position of the placenta alone determines the nature of the gestation, and the attachment of the placenta to the free surface of the peritoneum has never been demonstrated. The author states that evidence is now rapidly accumulating to the effect that extra-uterine gestation at or beyond the fourth month is extraperitoneal—*i. e.*, while the fetus may be intraperitoneal or extraperitoneal, the placenta is always extraperitoneal. In opposition to the older teaching on the subject, the author declares that the necessary elements for the placenta are on the one hand the fetal villi, on the other hand the connective tissue of the scrotina; that the covering of the villi is entirely and always fetal; and that the villi at their tips have an active phagocytic action. In the early tubal stages of extra-uterine gestation we do not know what relation the placenta bears to the epithelium, or whether, indeed, epithelium is present at the site of its earliest growth. In the latter stages, however, it develops entirely in relation to connective tissue. He therefore believes that the extraperitoneal development of the placenta is quite in accordance with modern views of the structure of the human placenta, and the belief that the extra-uterine placenta in so-called abdominal cases has developed on peritoneal epithelium is quite unwarranted.

While in the treatment of extra-uterine pregnancy no hard and fast rules can be laid down, there is no doubt in the author's mind that operative treatment is indicated, and that all attempts to cure by means of electricity, morphia, etc., are effete, or should be. While there is no difference of opinion as to the advisability of the removal of the fetus in the operation, considerable difference exists as to the placenta. The separation of the placenta in many cases has been attended by so much hemorrhage as to deter the operator. The author, in the present paper, records a case showing that this can be done with comparative safety when the iodoform tampon is employed, and that the placenta can be removed on successive days with advantage. Indeed, in certain cases, he does not see why the operator should not incise the sac abdominally and remove the fetus, plug the sac with iodoform gauze, and then remove the compressed placenta in a day or two.

In the case reported both fetus and placenta developed extraperitoneally. In all cases of extra-uterine gestation the site of the placenta determines the nature of the gestation. The fetus may become intraperitoneal after being tubal or extraperitoneal; but, as a rule which as yet knows no exception, the placenta, while arising in the tube and developing in the connective tissue of the pelvis, does not become intraperitoneal in the sense of ever grafting itself on the free surface of the peritoneum.

In conclusion, the author emphasizes his belief that the treatment of extra-uterine gestation must be operative, and that the operation should be undertaken as soon as possible. In early non-pediculated cases the fear of hemorrhage from the necessary separation of the placenta is irrational. The operator can separate and plug the sac with gauze; and if entire separation is impossible at first, it can be completed in a few days afterward. The opening in the sac should be left large, and it will be found that drainage goes on perfectly by means of the gauze until a glass tube can be substituted.

Appended to the paper is a report by Dr. Gulland as to the structure of the placenta removed by Dr. Hart.

**Clinical Contributions to Abdominal Surgery**

is the title of a paper by Dr. Paul F. Munde. The cases reported comprise the following:

1. Six cases of celotomy for ectopic pregnancy, all of which occurred during the past twelve months—four of them, indeed, with the mysterious habit of rare cases, within four weeks. All the patients recovered.
2. A large double pyosalpinx; recovery.
3. Epithelioma of the corporeal endometrium, with fibroids of the body; vaginal hysterectomy; recovery; relapse six months later.
4. Sarcoma of the body of the uterus, with small fibroids; complete abdominal hysterec-

tomy; practical recovery from operation; death after five weeks from the consequences of an old œsophageal stricture and gastric diverticulum.

5. Abscess of the ovary, with perforation into the large intestine; enucleation of the abscess sac; suture of opening in the bowel; recovery.

In the first two cases of extra-uterine gestation the diagnosis of unruptured tubal pregnancy was made, with almost absolute certainty. In the other four cases the probable diagnosis of ruptured tubal pregnancy was made, and verified by the operation. In no case was the fetus found. Curious to say, in five cases the left tube was involved; in one case only the right. The author states that he has, to his knowledge, seen but six other cases of undoubted ectopic pregnancy.

The author reports the case of double pyosalpinx as an instance of what he considers should be called by that term—that is, tubes distended with pus so as to form an appreciable tumor of oblong shape. The presence of a small amount of pus or muco-pus in an inflamed and hypertrophied tube does not, in his opinion, constitute a true pyosalpinx. True pyosalpinx he has not found to be very common. Tubes containing pus or muco-pus in so small a quantity as not to distend the tube, and apparent only after the tube is opened after its removal, are merely purulent salpingitis, not true pyosalpinx. The author thinks this distinction should be made, since the majority of cases of inflamed, hypertrophied, occluded and adherent tubes are of the latter variety, and do not represent tubes which are liable to rupture and cause fatal peritonitis. The author is also of the opinion that such tubes are not dangerous to life necessarily, and do not call for speedy or immediate removal. A tube distended with pus is always dangerous to life and indicates either removal by abdominal section, or, if adherent to Douglas' pouch and pointing at the vaginal roof, incision and drainage through that channel. When both tubes are distended with pus, whether loose or adherent, their removal by abdominal section is unquestionably the best and safest method.

(Many abdominal surgeons will take exception to the incision and drainage of pus tubes through the vagina, advocated by the author. We believe that the best treatment of true pyosalpinx, whether adherent in the pouch of Douglas or not, is their removal by abdominal section. We are sure by this means of removing all foci of pus, all collections of purulent matter, which cannot certainly be done by the incision and drainage method.—ED.)

In regard to the case of epithelioma of the corporeal endometrium, with fibroids of the body, the author states that the occurrence of fibroids with malignant disease is not by any means so rare as was formerly supposed. He has several times seen cancer of the cervix together with fibroids of the body; but the occurrence of fibroids and malignant disease in the body of the uterus is rather more rare, although there is no logical reason why a fibroid should not develop in the outer tissues of the uterus and malignant degeneration of the deeper structures occur subsequently. In this case the disease appeared to be limited to the uterine mucosa; but it must have been more deeply seated, since it reappeared six months after, in the cicatrix. The patient died one year after the operation. The ultimate result in this case has shaken the author's confidence in the radical cure of carcinoma uteri by vaginal hysterectomy. No more favorable case for a permanent cure could be imagined, he says, so far as previous examination could determine.

The article is illustrated with photographs of the specimens removed.

**The Antiseptic Treatment of Endometritis**

is discussed by Dr. C. S. Bacon. After discussing the microbic theory of the origin of inflammations, the author gives the following rules for the introduction of the sound, curette or any other instrument into the uterus:

1. Do not expect to complete the preparation of the patient with less than fifteen minutes of hard work.

2. Never make the examination at the first visit of the patient. Instruct her how to take a vaginal douche, and direct her to use sublimate douches twice a day for three or four days. If immediate examination is required, let it be done at her home or in a hospital, with all the preparatory details of a surgical operation.

3. Thoroughly disinfect the external genitals and surrounding skin.

4. Disinfect the hands and instruments, including the irrigating tip, which should be a glass tube.

5. Wash the vagina with a solution of lysol or creolin. A liquid soap, like Lee's or Johnstone's, is quite necessary. With two fingers, either with or without sterilized gauze or cotton, thoroughly scrub every part of the vaginal wall.

6. Introduce a Neugebauer speculum, which is better than any form of Cusco's bivalve, for it is asepticizable; and better than a cylindrical speculum, for it is much easier to work through.

7. Disinfect the cervical canal by means of a cotton swab, using first the liquid soap, then a strong creolin solution, and finally alcohol. Never introduce an instrument without seeing the cervical canal.

The author believes that the carrying out of these rules will prevent all except postpartum, post-abortum, and gonorrhœal endometritis and salpingitis.

The prevention of the extension of an acute gonorrhœal inflammation from the vagina to the endometrium is an important and serious problem. The tenderness generally prevents the thorough use of a vaginal douche. In children we must keep in mind the possibility of the irrigating tube being so firmly grasped by the vaginal sphincter that the fluid and secretion may be carried into the uterus; this can be prevented by providing a return flow. In addition to the use of the douche, every four to six hours a suppository of iodoform or bismuth subgallate can be used with advantage.

A useful adjunct to the various methods of treating endometritis, by means of applications, the curette, etc., is drainage; but gauze is, in the author's opinion, very poor material for a drain, the cross fibres keeping back or wholly preventing the flow. The author prefers wicking; but in the use of drainage he utters a note of warning in that the drain may furnish a ladder for the bacteria to enter the uterus, hence the vaginal end should be as well protected from the outside as possible by cotton tampons. While the value of drainage is unquestionable, he believes that many cases have been made worse by its use. This is because the plug of gauze acted as a dam instead of a drain, and because no attention was paid to the reverse current from the vagina. The curette is only one part of the treatment—simply an auxiliary to prepare for the antiseptic agent. In this respect it differs from the strong caustic, which has both a denuding and a germicidal action. When the curette is used carefully and thoroughly, however, and followed by an efficient germicide, the author believes that it is a more reasonable surgical procedure than the caustic. The debris produced can be at once removed and the extent of the curettage definitely controlled. The caustic causes a slough that must come away, and during this process there is the persistent danger of fresh infection.

Mild astringents or stimulants, like weak zinc chloride or iodine solution, are often harmful, because they serve as carriers of contagion; but when they are used with antiseptic precautions they may in suitable cases be of considerable benefit. The author regards their action as not solely nor chiefly antiseptic, but believes that they also modify the blood and lymph circulation and thus stimulate the antiseptic properties of Nature.

In speaking of the use of electricity in endometritis the author says: "A current of sufficient strength to have direct germicidal properties is too strong to be used in the uterine cavity. It is not advisable to use a current strong enough to produce a cauterizing effect. The galvanic current is a valuable agent in controlling hemorrhage, in cases of hemorrhagic endometritis, by virtue of its well-known effect on the circulation. The anode should be applied to the endometrium.

Dr. Joseph Eastman furnishes a contribution to the

**Technique of Suprapubic Hysterectomy.**

The great problem, in suprapubic hysterectomy has been what to do with the pedicle. In the method of suprapubic hysterectomy which the author has been working to perfect, it is sought to have no pedicle at all. For the last four years the author has also been trying to reduce the number of ligatures used. Recently he has devised an instrument, in appearance much like a gouge, which he states has enabled him to perfect his method of dispensing with ligatures, except those which tie off the ovaries, Fallopian tubes, and the upper part of the broad ligaments. The abdomen being opened and the broad ligaments tied off so as to secure the ovarian arteries, with button-pointed scissors he girdles the tumor below the place where the elastic ligature would usually be placed. He begins with these scissors and cuts around the line mentioned, drawing up the capsule anterior and posterior. He then peels down the capsule of the tumor and cervix with this gouge, as a glove finger would be pushed down and off with a spatula. He then passes his hysterectomy staff up the vagina, cuts into its groove, and draws a strip of bismuth subgallate (dermatol) gauze through the fenestra of the staff. Withdrawing the staff, the gauze is drawn down into the vagina. Then packing the pocket with the upper end of the gauze, folding the flaps of the capsule and uniting them with silkworm gut so as to secure sero-serous approximation with drainage from the vagina, he closes the abdominal wound, only keeping in a small Eastman drainage tube.

Dr. John T. Winter contributes a paper on

**Puerperal Eclampsia—Its Therapeutics.**

The author says that Bright's disease existing before pregnancy should not cause an unfavorable prognosis, and reports a case in support of this opinion. A knowledge of the premonitory signs is necessary to an early and successful adoption of preventive treatment, consequently the urine of the pregnant woman should be examined at least once every two weeks during the latter months of pregnancy, especially in those cases where there is œdema of the face, in primiparæ, and in those whose urine has at any time contained albumen. Having detected any of the well-known premonitory symptoms, we must vary our treatment according to the condition of the patient. If she is strong and plethoric, we should give an active saline cathartic and put her on an unstimulating diet. If, on the other hand, she is anæmic, a mild laxative and a nutritious diet should be ordered. If there is œdema with albuminuria, diaphoretics and diuretics should be given, jaborandi being, in the author's opinion, perhaps the best. The wine of colchicum, in as full doses as can be borne, is said to be an excellent remedy. The author also believes that cups applied freely over the kidneys might be of value in these cases. During a convulsive seizure certain precautionary measures should be adopted. The tongue should be properly protected from injury, the clothing should be loosened to prevent any obstruction to free circulation and respiration, and the patient be unrestrained as far as possible. In order to remedy any possible irritation from the presence of undigested food in the stomach, an irritant emetic should be given. Ten grains of the sulphate of copper dissolved in a wineglass of warm water, or the hypodermic injection of the one-tenth of a grain of apomorphia, will usually be found efficacious. If the irritation is in the intestine, or if there is constipation, a seidlitz powder, calomel, elaterium, or even croton oil should be given, or an enema of an ounce or two of Epsom salts in half a pint of warm water should be thrown as far up the bowel as possible. Cathartics do good not only by

unloading the intestinal canal, but by causing general as well as local depletion. The production of catharsis is the surest method of relief in dropsies, as well as in hyperemia of the brain, where cathartics do good not only by depleting but by acting as revulsives. In regard to the use of anæsthetics, the author advises the use of chloroform not so much during the paroxysm as in the interval, keeping the patient under its influence till the time of the expected recurrence is passed. By a judicious interruption of its employment it can be continued, in suitable cases, for twenty-four hours or longer; but it requires to be used with great caution, its exhibition being contra-indicated where the circulation is depressed or where there are any apoplectiform symptoms.

The various somnificants are also considered, and the author warns against the use of chloral in persons with weak or fatty hearts. Opium is also advised in the treatment of eclampsia. In convulsions from irritation following labor, as from a clot of blood in the cervical canal, the removal of the clot and the hypodermic injection of one-fourth of a grain of the sulphate of morphine is all the treatment that the author has found necessary in several instances. In regard to antipyretics, two fifteen-grain doses of antipyrin are reported to have caused the cessation of the convulsions in a woman six and a half months pregnant. She went to full term but the child was still-born. In regard to diaphoretics and diuretics, the author speaks of jaborandi as perhaps as safe in dropsies as any other remedy comparable with it in power. He further says that to him jaborandi seems to be the most valuable single remedy that we have as a prophylactic against puerperal convulsions. It produces excessive diuresis and diaphoresis, and proves a most valuable agent in relieving the dropsical accumulations. He has used the remedy in several instances with excellent results. Of the depressants he says that calabar bean is rather limited in its therapeutics. Nitrite of amyl may be useful after a paroxysm when the heart beat is almost imperceptible, on account of its power of dilating the blood vessels and increasing the heart's action. The remedy must not be pushed too far, nor must it be given when the face is flushed or if the pulse is full and strong, as it might produce not only uterine contractions but uterine hemorrhage as well. The bromides have superior claims as curative agents in puerperal convulsions, though the author would not like to discard either chloroform or morphia for them. He uses bromide of potassium because of its action as a sedative to the motor system, followed by general nervous sedation. The drug does not act during a paroxysm, but restores tone and diminishes the tendency to spasms. Veratrum viride and venesection are also discussed and the opinions of various observers quoted as to their usefulness.

Induction of labor should only be resorted to when there is no longer any possibility of saving both mother and child. The author advises the injection of an ounce or two of glycerin between the placental and uterine walls for the prompt induction of labor pains.

Dr. Casey A. Wood contributes a paper on

**Puerperal Panophthalmitis due to Septic Embolism,**

reporting a case. The author says that it is a fact not dwelt on in any of the text-books on ophthalmology, or even in the larger works which treat of the diseases incident to the puerperal period, that a woman, during or shortly after parturition, should be liable to complete loss of vision, in consequence of the carrying of detached intra-uterine particles through her circulation into the blood vessels of the eye. He asserts that the disease begins in the deeper structures of the eye instead of beginning in the superficial coverings of the eye and working inward, as has been taught. The prognosis, so far as the life of the patient is concerned, is always very grave. The case reported by the author is one of the very few on record where both eyes were affected and yet life was preserved.

Dr. Weller Van Hook discusses "Abscess Formation in the Patent Urachus," reporting a case. After discussing the pathology of the condition very thoroughly, the author gives, among other causes, the obstruction to the outflow of urine in post-natal life as responsible for the dilatation of a persisting duct to a channel of considerable size. The diagnosis of the case reported was made by exclusion. The treatment at first was daily irrigations with peroxide of hydrogen solution, with drainage by means of gauze introduced into the umbilical opening. Later, the opening was dilated and a small drainage tube introduced. The cavity closed in about a week.

Dr. Howard A. Kelly, in a paper entitled "The Advantage of Atmospheric Distention of the Rectum, with Dislodgment of the Small Intestines, in the Bimanual Examination of Uterus, Ovaries and Tubes," advocates the procedure, which is done by opening the anal orifice by means of a small speculum or tube, with the patient in the knee-chest position, thus allowing the rectum to become distended with air. By this means the author says that the rectal examination of the uterus and adnexa is rendered easier and diseased conditions are discovered more readily. It is needless to say that, before making such an examination, both bladder and rectum should be emptied.

Dr. Henry L. E. Johnson reports "A Case of Double Ovariotomy," and Dr. Grace Peckham-Murray concludes her paper on the "Mechanism and Treatment of Complete Procidentia Uteri," giving in this number the various methods of treatment advocated by different writers and operators. Massage has not been of much use in this condition. Alexander's operation is condemned. Ventrofixation and hysterectomy are regarded as too radical. The new operation devised by Freund is looked upon as offering good results. This consists in encircling the vagina with silver wire sutures, quilted in at equal distances, beginning near the cervix. The article is copiously illustrated with cuts of the various operations advocated by writers on the subject.

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## MEDICINE

### Labor and Heart Disease.

Tarnier (*Jour. des Sages-Femmes*) notes that in heart disease all great and sudden efforts put the patient in peril, and labor is no exception to the rule. Running upstairs, racing to catch an omnibus or train and sexual intercourse may all cause fatal syncope. The danger of labor is not special in this sense; it is dangerous in heart disease simply because it involves much effort. Tarnier induced premature labor in a lady who was subject to advanced heart disease. Notwithstanding all precautions, she became moribund in the course of her labor. Directly she died, he turned and delivered a live child, which survived. A woman was brought into Tarnier's wards in January, 1894, in labor, with advanced heart disease and asystolism; she was apparently dying. Immediately about 300 grammes of blood were withdrawn, and the symptoms of suffocation diminished. The patient grew calmer. As it was extremely advisable to bring on labor quickly, as the forceps is apt to fatigue the patient, and as, in particular, the child was dead, the basiotribe was applied and delivery effected. A few days later the mother was doing very well.

### Radical Method of Curing Corns Between the Toes.

Dr. A. M. Phelps advises that in case of corns between the toes, which after ordinary treatment recur, the skin between the adjacent toes should be entirely removed and the toes brought together by a line of sutures and allowed to unite. The webbing of the toes is entirely unimportant.

### A Rarely-Noted Symptom in Nervous Affections of the Intestines.

Dr. Lahnsen (*Muench. Med. Wochenschr.*) after describing the usual symptoms in so-called nervous dyspepsia, calls attention to a peculiar pain on pressure of the celiac plexus, which is commonly overlooked. This plexus lies upon the anterior wall of the aorta, immediately below and in front of the aortic opening of the diaphragm on the left side. The continuation of this plexus is the superior mesentric plexus which supplies the whole of the small and large intestines, with the exception of the rectum and descending colon. If we press downward from this situation, after previously emptying the abdomen, if necessary, the patient will invariably complain of pain. This pain, on pressure of the nerves on the left side, is a very characteristic symptom.

His method of treatment is as follows: He allows the patient a general mixed diet, forbidding only carbonic acid drinks and food causing flatulence. At night the whole abdomen is surrounded by moist towels, followed in the morning by cold rubbings, then a glass of a natural spring water, a walk and a light breakfast consisting of coffee, bread and butter. Later, electric or steam baths, followed by massage of the abdomen. After dinner, consisting of a mixed diet with a glass of wine, rest for one and one-half hours, followed by electric sitz-baths and gymnastics, with especial regard to abdominal movements. Supper at seven o'clock, at which one or two glasses of beer can be allowed. Patient to go to bed at 9.30.—*American Medico-Surgical Bulletin.*

### Bites or Stings of Insects.

A saturated solution of camphor or salol in ether may be applied with benefit. Or the spot may be painted with:—

℞ Collodion ..... ℥iiss.
Salicylic Acid ..... gr. xv.
Benzoic Acid ..... gr. xv.
M.

—*La. Med. Mod.*

### The Removal of Gunpowder Stains.

Dr. W. M. Nelson describes in the *New York Medical Journal* a case in which he employs the method of Dr. Ohmann-Dumesnil for removing the tattooing produced by explosions of gunpowder. The process consists of tattooing the affected surface with a glycerole of papoid. The case cited by the author was one in which the papoid was applied soon after the injury was received; and it would be interesting to know if the same process would apply to cases in which the pigmentation had been of long standing.—*Times and Register.*

### Phthisis.

Professor Bouchard prescribes:—

℞ Beech-wood Creasote..... 5j.
Balsam of Tolu..... 5i¼.
Terebinthine ..... ... ..... gr. xv.
Benzoic Acid ..... q. s.

M. Make into 80 pills, and let 10 pills be taken daily.

Or,

℞ Beech-wood Creasote..... 5iss.
Codliver Oil..... Oi¾.

The formula for hypodermic injection devised by Morel-Lavallee is:—

℞ Iodoform..... 5j.
Guaiacol ..... 5i¼.
Eucalyptol..... 5iij.
Sterilized Olive Oil..... 5ij.

M.

To relieve cough Grasset gives the following pill:—

℞ Terpine..... gr. iij.
Codeine..... gr. 1-6.

M. Four or five such pills may be taken daily.

In the chronic form with adenopathies Grasset prescribes:—

℞ Iodide of Sodium..... 5iiss.
Bromide of Sodium..... 5v.
Chloride of Sodium..... 5x.
Water..... 5ix.

M. Sig.: Teaspoonful in a glass of milk morning and evening.

### A New Method of Treatment for Tonsillar Hypertrophy.

Ruault describes his method of removing hypertrophied tonsils. He claims it is superior to both the tonsillotome and ignipuncture in cases where such methods are usually employed. It does not cause bleeding like the former, nor pain, either immediate or consecutive, as does the latter. It enables one to operate with a precision and surety lacking in other methods. Cocaine having been applied to the tonsil, any crypts containing secretions are cleaned out, and such adhesions as may exist between the tonsil and soft palate destroyed. By means of a cutting forceps, one blade of which is flat and fits into the opposite one, which has a sharp cutting edge, small pieces of the projecting tonsil are then removed. After several pieces have been cut off, the raw surface is energetically rubbed with a swab of cotton moistened with iodine one part, iodide of potassium one part, and water six to eight parts. The discomfort arising from this passes off in a quarter or half hour. In a few days secondary reaction will have reduced the size of the remainder of the tonsil and, if necessary, any projecting pieces may be removed as before. Of eighty cases treated by the author in only three was there a necessity of operating a third time, except in the case of infants.

### The Dangers of Cocaine

Are recapitulated in the *American Journal of Ophthalmology* in a paper by Dr. Albert R. Baker, of Cleveland, who collects a list of ten fatal cases of poisoning by the drug. The smallest fatal dose where a measured quantity was given was two-thirds of a grain, which was injected into an eye with the result that immediate unconsciousness was produced, followed by death in four hours. One grain injected into the gums by a dentist produced death in a few minutes. The application of a ten per cent. solution to the larynx with a brush was also fatal, unconsciousness following almost at once and death in three hours. The author also reports a case where the instillation of a six per cent. solution into the eye was followed by alarming depression, with periods of unconsciousness attended with delirium. Other and similar cases have been reported.—*Northwestern Lancet.*

### Rubber-Tissue Gloves for Protecting the Hands during Operations, etc.

Dr. T. S. K. Morton has called attention to thin rubber gloves, which have been in the market for some time and are coming into use for general surgical purposes and for handling strong solutions. "I have found these rubber-tissue gloves extremely useful in handling offensive cases. With them it becomes a pleasure to make rectal examinations, because the skin of the hands does not become saturated with fetor, and it is wonderful how many more examinations one makes. Also in handling strong solutions, or even in operating upon septic cases they have an excellent field. The rubber is so very thin that it interferes very little with the tactile sense. As a rule, they go on with great ease and come off readily. The dealer said he was not sure that they would last very long in handling instruments, but thus far I have used them considerably, and they are still practically in perfect order. But if they could be used only a few times, the price, $2.50, with 40 per cent. discount to hospitals, is not excessive. I think them of great value when handling morbid growths, or making post-mortems, where it is possible to be inoculated. They bear steam sterilization and soaking in strong solutions of carbolic acid or bichloride."

## ORIGINAL ARTICLES.

### IMMEDIATE CAPSULOTOMY FOLLOWING THE REMOVAL OF CATARACT.*

L. WEBSTER FOX, M.D.,† Philadelphia.

All ophthalmic surgeons endeavor to obtain perfect vision after the removal of a cataract. On account of its prevalence, the loss of one of the most valued of the senses, and the restoration to vision by a bloodless and painless operation, have concurred to render this operation an object of the highest attention to surgeons; and the progress of improvement in the operation has been commensurate with the advances made in surgery elsewhere in the economy. Unfortunately, with all our skill and knowledge, success does not always follow the removal of an opaque lens. The many contingencies incident to the healing of the wound, the distortion of the cornea, the subsequent change in the media caused by iritis, or a thickening of the posterior capsule—one or all of these factors play a very important role in the subsequent restoration to vision.

The opaque lens, with its capsule, obstructs the vision, causing blindness of the patient. To remove this obstruction requires considerable dexterity; to restore vision, absolute cleanliness and most careful after-treatment. The most disheartening factor in a cataract operation is that sooner or later the posterior capsule thickens, and again dimness of vision follows; the lessening of the sight is not so great as it was before the removal of the lens, but still the patient is debarred the comfort of reading, writing, or attending to business matters in which it is necessary to have perfect vision. It is to prevent this latter change that I advocate the splitting or parting of the posterior capsule at the time of the primal operation.

Having had the opportunity of following many operators, good, bad, and indifferent, and noting the after results, I frequently saw excellent vision follow bungling manipulation. The surgeons did not possess that delicate sense of touch so essential in making the corneal incision, snipping the iris, lacerating the anterior capsule, and delivering the lens. They lost courage, or their hand became so tremulous after they had ruptured the capsule, that the operation would have been a failure had they not taken a lens scoop in hand, entered the eye, and fished out the cataract and its capsule, with always more or less loss of vitreous. With very great care in the after-treatment, many of these patients would recover, and in the majority of cases which did recover, no capsule interfered with their visual acuity. It was witnessing such operation that led me to think that a parallel process, carried out, however, on more delicate operative lines, at the time of the primary operation, would still lessen the dangers that such harsh measures would be sure to excite.

The ancient method of removing cataracts from the direct line of vision was by *couching;* that is, passing a delicate needle through the sclerotic coat on the temporal side of the eyeball, posterior to the ciliary bodies; pressing it forward and into the

* Read before the State Medical Society of Pennsylvania, May 17, 1894.

† Professor of Ophthalmology, Medico-Chirurgical College.

crystalline lens. Then, by a backward sweep of the point of the needle, lens and capsule were torn from their position and deposited down and out in the vitreous chamber. Celsus, the celebrated Roman physician, who lived at or about the commencement of the Christian era, describes, and is generally esteemed the father of this operation. It was not very satisfactory in its results, according to the data obtainable from the earlier writers. Fabricius, who flourished in 1600, speaks with great despondency of this operation; later on, Hiester, 1711, says: "Though the operation is easy to be performed the success is so very precarious, that amongst a great number of persons couched by the most distinguished oculists, very few met with the desired results; and upon the vast number of patients upon whom the celebrated itinerant, Taylor, operated, not one in a hundred recovered his sight." He further says, "that in several different places he saw many miserable objects in tormenting pain, arising from inflammation consequent upon the operation, and that of those who regained their vision, there was scarcely one in ten who did not sooner or later lose it again." For eighteen hundred years this puncturing of the eyeball, with its most deplorable results, was the only method held out to the blind. It was the outgrowth of an accident which gave birth to the rival plan of extracting the opaque lens through an incision of the transparent cornea. It was the failure to remove a cataract which had escaped into the anterior chamber by couching, that led M. Mery to recommend, in the year 1707, the practice of extraction in all other cases of this disease. It was left, however, for Daviel, the celebrated surgeon of Paris, 1745, to bring forward this method as one infinitely less dangerous than couching. From that day to this the incision is made through the cornea, or along its margin, and the percentages of loss is to-day what the gain of vision was one hundred and fifty years ago.

### PRELIMINARY TREATMENT ESSENTIAL IN CATARACT OPERATIONS.

I deem it of the greatest importance to interrogate all cataract patients presenting themselves for an operation, as to their general habits and family history, and to make a careful examination of the urine, restricting meat diet and increasing a vegetable one; while last but not least, placing the patient, one week before the operation on the mixed treatment, also paying particular attention to bathing both eyes with a boracic solution containing sulpho-carbolate of zinc; examining the eyelashes and particularly the nasal cavities. If any catarrhal affections are found in these cavities, it is of paramount importance that they receive the proper treatment before an operation is performed. The day before the operation, the patient is given a warm bath and a saline purgative, kept in bed, and his face washed with castile soap and water, then washing the skin around the eye to be operated upon with ether, following this again with a 1:5000 solution of corrosive sublimate, after a German method (Schweigger).

The reason I call attention to these minute details is that the patient may suffer from some defect which would not affect an eye in a comparatively healthy state, but might exercise an extremely pernicious influence on the eye after the irritability following the operation. The effect to be dreaded is inflammation, and therefore every measure calculated to prevent its occurrence must be taken. There are still a few ophthalmic surgeons who think it quite unnecessary to take these preliminary precautions, but, happily, the number is growing less year by year.

At the time of the operation, still greater precautions are taken; the patient's face, neck and mouth are thoroughly cleansed; clean underclothing, over which, and fitting close to the neck, a sterilized sheet is wrapped; head bandaged in a sterilized towel, and the eye irrigated with an aseptic fluid, as hot as the patient can bear it. The instruments are also sterilized; all fluids, such as atropine and cocain, are sterilized in a Llewellyn flask. The operation is performed then in the usual manner.

After the delivery of the lens (cataract) and all cortical matter is washed out of the anterior chamber, I proceed with the rupturing of the posterior capsule—the subject of my paper. The instrument used is a gold enameled hook, made as delicately as is consistent with keeping its shape. It is of malleable steel, so that it may be bent to any angle which I find is convenient, especially when the eye of the patient lies deep in the orbit. The hook is passed into the anterior chamber,

and behind the lower pupillary margin of the iris, on its flat side. It is then rotated backwards, hooked into the capsule, drawn gently upwards to the mouth of the incision, rotated on its flat again, and then taken out of the chamber. By this means, the capsule is torn, and the vitreous presses forward between the rent. Very little or no vitreous shows at the mouth of the wound. If it does, I snip it off.

When the operation is performed after the simple method (without iridectomy) the same manipulation is carried on with but one exception; and that is, the line of incision is not so long. The ophthalmostat is removed, and the eyeball again irrigated with hydrostatic eye-douche, followed by dropping one drop of sterilized Atropia solution into the eye; the lids closed and thickly anointed with vaseline, which has been sterilized by boiling; over this, specially devised eye-pads, which have also been sterilized by heat, held in place by adhesive strips, which keep the bandages, securely fixed, permitting the patient to change his position in bed as often as desirable. In twenty-four hours the dressings are removed, and both eyes bathed with warm water, and irrigated with the sulpho-carbolate solution, another drop of Atropia applied, and similar eye-pads adjusted with as much care as at the primal operation; and so continued from day to day until the eye is out of danger.

Is this a new operation? Some of the older writers of fifty years ago, hint at the removal of the lens and its capsule, but they are not explicit enough to say that they did so. The only authority that I can find saying so positively, is Richard Middlemore, who on page 138, Vol. II, in his great work on "Diseases of the Eye," published in 1835, after speaking of the removal of the lens, when the pupil is not clear, on account of the thickening of the posterior capsule or the hyaloid membrane, says: "In every such instance, I have found it absolutely essential to the successful result of the case, to lacerate the posterior capsule and hyaloid membrane, and permit the escape of a portion of the vitreous humour." Coming nearer to our own day, I must say a few words about the distinguished surgeon who left his impress upon all who witnessed his wonderful skill as an operator. I have reference to the late Dr. Richard J. Levis, of this city. I have had the opportunity of examining quite a number of patients, from whom cataracts were removed by this eminent surgeon. In nearly every instance the posterior capsule was evidently ruptured at the time of primal operation. Whether this was a constant practice of Dr. Levis' I am unable to say, but I am sure he realized the importance of removing the posterior capsule at the time of the original operation. Pagenstecher, of Wiesbaden, is also an advocate of removing the lens and its capsule at one sitting. Hasner, another German ophthalmologist, is an advocate of this radical operation. It has recently come to me indirectly, that Dr. Knapp, of New York, is also lacerating the posterior capsule at the first operation.

Is the operation always successful? Laceration of the capsule alone does not prevent the hyaloid membrane from becoming slightly translucent. When this takes place, we may follow with a needle operation, and not provoke cyclitis by trying to tear a tough, inelastic tissue.

I have been in the habit of performing this operation in alternating cases, for ten years. In those patients upon whom the operation was performed, I had to repeat a needle or capsulotomy (scissors) in about fifteen per cent. of the cases. Where it was not performed, in about seventy-five per cent. In the fifteen per cent. of the cases where it did not succeed, I can only attribute it to a very thick posterior capsule, the vitreous receding after closing of the eye-ball, and thereby not keeping the capsule separated, but practically closing again. My experience has led me to believe that there is less danger of inflammation of the eye-ball in immediate capsulotomy, than in a subsequent operation.

The elder operators recognized the gravity of puncturing an eye-ball with a needle, and hailed with delight the improved method which completely revolutionized statistics. My own experience is fast leading me to adopt the cutting through the cornea with keratome and the incision of the capsule with a De Wecker's scissors, disregarding the needle altogether. With the preliminary treatment, and with the aseptic methods now employed, success is almost always assured; whilst with the treacherous needle, almost every surgeon has had reason to regret this modus operandi in more ways than one.

# BATHING, SWIMMING, AND DIVING AS CAUSES OF AURAL DISEASE

LAURENCE TURNBULL, M. D.,* Philadelphia.

Before entering into an account of the manner in which the ears of bathers are affected, it will be of interest to consider the construction of the ear in animals living a portion of the time submerged in water. A large number of marine quadrupeds may be included in this class, such as the crocodile, seal, hippopotamus and the like. These animals can remain under water a long time before coming to the surface for the purpose of breathing, and it is found that the construction of their ears is such that no damage occurs to the organ from frequent excursions under the water, which is colder than the surrounding atmosphere and would be irritating to delicate structures.

Some of the lower orders of marine life living exclusively in the water, have no special auditory nerve but receive sound impressions by means of shock imparted to the body.

The tympanic membrane and other parts necessary to sound transmission in mammalia are said to be absent in snakes and many saurians, though lizards and frogs have an exposed drum-head. Moles are said to have a closed external auditory meatus which excludes earth in burrowing; and the camel when exposed to the sand-laden simoon of the desert has the ability to contract the nostrils at will.

Swimming and diving in cold water is a frequent cause of disease of the external auditory canal and external surface of the membrana tympani, as also of the middle ear, though bathing in river or sea water is, when wisely and properly regulated, both healthful and pleasant. The evils attending bathing and swimming in cold water are the entrance of this cold fluid, not only into the external meatus, but as far as the membrana tympani, causing inflammation of the lower portion of the auditory canal, and of the anterior surface of the tympanic membrane. A still greater evil is from sudden deglutition, *i.e.* making the effort to swallow during diving or swimming, by which—the mouth, nose and pharynx being filled with cold water, and the mouths of the Eustachian tubes open—a portion of water passes into the middle ear. This result rarely occurs in expert swimmers and divers, but is most common in beginners, who from cold, or the shock of the contact with the water suddenly breathe or swallow in a sobbing manner. We have, however, known it to occur in old and experienced swimmers while plunging head foremost, termed a "header," owing to the intense coldness of the water the act of deglutition being involuntary. Bathers in the surf are liable when off their guard to be struck by the waves upon the ear with much violence, especially in boisterous weather at full tide. Cold salt water may thus enter the external auditory canal with sufficient momentum to rupture the drum-head, especially in persons having a large, freely open canal. Swimming or floating upon the back, especially the latter, when the ears are submerged, or diving and swimming beneath the surface, often exposes the ears very much to the entrance of the water.

The lovers of sea-bathing will learn with much interest the result of a series of observations on the temperature of the sea, which were completed some time since by the Scottish Meteorological Society. The observations were made every day during a period of four years and nine months, and the result was to confirm the impression that the changes of atmospheric temperature influence the sea but slowly. The variations in the warmth of the sea-water occur within a range one-third less than that of the air; and the mean temperature of the sea is found to be warmer than that of the atmosphere in seven months out of the twelve. The summer warmth penetrates the sea very gradually, and is more gradually given off. January is the coldest month, but the sea-water is coldest in March. July is the hottest month but the sea-water attains its maximum warmth toward the end of August. From that time the sea becomes warmer than the air, and cools so much slower than the weather that in November the average warmth of the water is six degrees, and in December seven degrees, higher than that of the atmosphere. The balance is reached at the end of March,

* Aural Surgeon to the Jefferson College Hospital, etc.

and then for the next five months the air is warmer than the water.

These figures, which result from careful observations made at Peterhead, justify the custom of extending sea bathing late into the autumn. Sea bathing should, in fact, begin late and may safely end late. It is more dangerous in the warm days of early summer than in the chilly days even of the late autumn. The sea is as warm at the end of October as it is in the second week of June, and the period between these two dates is the healthy bathing season for those who are strong enough to begin early and leave off late.

If the water is not removed by placing the head to one side, and drawing the external ear forcibly outwards, shaking the head at the same time and opening the mouth, also striking the external ear with the palm of the hand, it is apt to cause inflammation as the water decomposes, followed by perforation of the membrana tympani; or, the inflammation with the formation of pus, if neglected, may pass inward to the middle ear, cochlea and labyrinth, and implicating the brain, may terminate in death.

It is a well recognized maxim among those who devote special attention to diseases of the ear, that no cold fluid should be allowed to enter even the external auditory canal; still this important fact is not sufficiently recognized by the profession at large. The entrance of warm water into the ear is less objectionable, but even this is not quite free from danger, and has its disadvantages; and the water should in all cases contain a few grains of saline ingredient, like borax, soda, or common salt, a teaspoonful to the pint, when employed in washing out the ear. The symptoms of water in the middle ear are, in the first stage, an uncomfortable sensation followed by earache or pain, which after a time, if neglected, becomes agonizing, and is accompanied with great tenderness behind the auricle. In proof that water in the ear is injurious and causes deafness, we might cite a number of instances. It is a well known fact that dogs which are *thrown* into the water become deaf.

Many cases of this form of disease in its chronic stage, come under treatment during all seasons, but acute cases from swimming and diving, occur during the spring and summer months, chiefly in boys from eight to sixteen years of age; a much smaller number occurring in the fall and winter. If the acute form be promptly treated, entire recovery takes place; but should the case not be seen until after the chill, it is always followed by a discharge of shorter or longer duration.

The following is a summary of the aural diseases and complications of existing diseases for which patients applied for treatment:*

Acute purulent otitis media; chronic purulent otitis media (from repeated exposure in bathing); acute catarrhal otitis media; subacute catarrhal otitis media; acute exacerbation of existing chronic purulent otitis media; otitis externa diffusa; otitis externa circumscripta; otitis externa exudativa; myringitis (either independently or in connection with inflammation of the external auditory canal); impaction of cerumen; otalgia due to exposure, etc.; aggravation of symptoms arising from chronic catarrhal inflammation by abuse of sea bathing (bathing frequently and remaining in the water too long).

In cases not recognized, the symptoms of violent headache, furious delirium and coma, give the physician the impression that disease of the brain is present, and the cases thus improperly treated sometimes terminate in death. The morbid condition in the first stage consists in acute inflammation of the extremely delicate mucous membrane lining the middle ear. The inflammation is followed by effusion of fluid, and after twenty-four hours by the formation of pus. It is in every instance attended by fever, with swelling and inflammation of the naso-pharyngeal space and great pain. If this fluid or pus be removed by incision into the membrana tympani, followed by the use of the air douche and injections of hot antiseptic wash, the patient recovers and the ear is saved. The patient is apt to remain deaf for several weeks, and the use of Politzer's air douche is necessary to keep the Eustachian tube open; the local application of tincture of iodine brushed over the mastoid facilitates the removal of the inflammatory thickening. To diminish the discharge of pus, should it continue, we may employ a powder of boric acid, blown into the meatus before it is washed out,

* Sexton—"The Ear and its Diseases."

and reapplied twice a day until the discharge shall have ceased and the perforation become closed.

In Australia and India, where they have a very hot climate and most of the towns are on the sea coast, the people bathe very frequently, some even three times daily, from June to October. During these months it has been noticed (Dr. Kenny) that the number of patients suffering from ear troubles has been considerably augmented. They bathe in large enclosures for fear of the sharks, and these baths have a depth of water from twelve to sixteen feet. At these great depths the bathers are constantly diving, and added to the irritation of saline water in the auditory meatus, there is also the great increase of pressure to which the membrana tympani is subjected.

Dr. Macnaughton Jones has noticed the occurrence of exostosis within the meatus to persons very fond of sea bathing. The ears, when tender or diseased, in ladies should be protected in bathing by an oil silk cap, while gentlemen should place a piece of wool in the ear, or some form of protection which can be removed as soon as the bathing is over.

*Russian and Turkish Baths.*—Acute inflammation of the middle ear, etc., is liable sometimes to occur after the use of these baths, which render the patient extremely susceptible to cold and consequent catarrh of the upper air-passages.

Sexton reports four cases of aural disease resulting from long continued indulgence in the Turkish bath. Two of these patients had chronic purulent otitis media, and one chronic catarrh of the middle ear, while one patient was suffering from acute inflammation of the auditory canal.

Six cases of acute purulent inflammation of the middle ear, resulting from the effects of getting water in the ears or from the susceptibility induced by baths of various kinds, were recorded: A shower bath in 1 case; hot water baths in 2 cases; hydrant water falling in the ear in 1 case; exposure after ordinary bath in 1 case; bathing when overheated in 1 case.

One patient, a male 40 years of age, who was suffering from chronic catarrh of the middle ear, attributed a marked increase of tinnitus aurium to taking a cold bath.

## THE INJURIOUS INFLUENCE OF WATER INTRODUCED INTO THE EAR BY THE NASAL DOUCHE OR SNUFFING UP COLD WATER.

We have explained the injury which results from the introduction of water into the auditory canal, also the serious disturbance produced by the same when passing into the Eustachian tube by very sudden efforts at swallowing, now the same results will follow the improper use of what is known as the nasal douche or in snuffing up cold water or solutions of medicinal substances. The first great point is to remember that the fluids should not be cold; the second, is that the head should be kept level and not thrown very far back; third, individuals using this method of cleansing the throat and back of the nose should not expose themselves to the open air for some time after using either of these methods. It is much better to use the steam or spray form of apparatus as less risk to the ears, and the result in a medical view will be as good, if not better, as cleansing agents.

The same results will occur from the post nasal syringe when improperly employed.

---

## COLD WATER TO THE SCALP AS A CAUSE OF EAR DISEASE.

The present fashion in young boys and even men in cutting the hair close to the scalp, both in summer and winter, is a cause of disease of the ear. It is a well-recognized fact that we hear with the skin of the scalp and the bones of the head, and irritation by dampening the skin impairs the hearing, and when cold water is applied too freely it will produce coryza and earache. Again, young girls saturate their hair in bathing and then allow the air to dry it. Bathing caps should be always used under such circumstances. The hair is a great protection from cold, and during the winter should be used to protect the scalp and throat. The new form of clipper by which the hair is cropped very close is a cause of earache, likely to follow inflammation of the middle ear, especially if the person is afterward placed in a car or carriage or cab, and the wind allowed full play on the part.

# COMMUNICATIONS.

## APPENDICITIS FROM A MEDICAL STANDPOINT.

T. L. McDERMOTT, M.D., Louisville, Ky.

The unfinished report of Dr. Cartledge on the classification of appendicitis, which was interrupted at our last meeting, and the exhibition of specimens of some late operations, suggested some comments on the subject from a medical standpoint. It was, therefore, made the special order for this meeting, and as I feel no more important question is agitating the public expectancy both here and abroad than this, I invoke by this method the local sentiment favorable or otherwise as to its advisability, and the character of cases deserving its application.

In this, as in many other of those heroic operations that enkindle the enthusiasm of the original promoters, and startle the laity with the wonders of science that thrills even the initiated, snatching from death the innocent victim, and restoring to health the misanthropic cripple, it certainly seems inexpedient for the unsurgical brother to dampen the ardor or quench the fire that illumes such desolate pathways. But, on the other hand, as license runs wild with its sensuous victories, and culprits stalk where angels fear to tread, the history of all these grand successes is blotted frequently by unrestrained excesses and the brilliant progress of the art destroyed by the unwary and the charlatan; and it does become at times the duty of the peaceful practitioner, standing apart as it were from the conflict between the knife and dissolution, to stay the hand grown riotous by acclamations.

Not that I expect to say anything new on the subject, worn threadbare possibly already, but simply to bring to a more vivid experience its faults and triumphs, as demonstrated at home. The unalterable fact obtains, however, that a sentiment is fast gaining assertion amongst the medical members of the brotherhood, who formerly after diagnosis relinquished without question their subjects to the knife, and contrawise amongst many of the adroit surgeons themselves there is already a disposition to eliminate many of their former operable cases.

Only a few years ago it became an open boast that laparotomy was, in skillful hands, a decidedly safe operation, so entirely harmless that it took rank among exploratory procedures, and it was growing as common to cut open the belly to elicit or confirm a diagnosis as to perform many of the minor operations; so much so that in many instances life was sacrificed in the useless search for supposed disease in healthy organs. Nor do I wish to affirm here that the quest was uncalled for, nor to blight the fame achieved in some of those undertakings, but I *do* assume that in many instances the gravest concern must follow imprudent proceedings.

The most serious obstacle to the fullest enlightenment naturally occurs from that want of frankness in the ranks of the profession itself, which interposes an almost insuperable barrier to a quick and decided solution of its utility; and for many reasons, but primarily because the experimentation which naturally opens so many new fields of conquest in surgical enterprise, only proves their availibility by continuous research, and they traverse many tortuous courses before the danger signal calls a halt. Secondarily, I presume the implied acquiescense to doubtful results, and the frequently unquestioned exhibition of specimens that do not fully bear out the alarming aspect the operator would have us affirm.

I have no doubt that many lacerated appendices could trace their origin to the inevitable rudeness that attended their separation, and seem to give credence to an urgency that calmer retrospection would deny. Of course the gravity of the responsibility where fatal results attend these operations, militates strongly toward the defense of measures attended by such fateful consequences, and whether the operation were wise or incompetent, a fellow feeling for the author would bias an untoward criticism of his work.

As I intend this introduction to the discussion of the evening as a prelude ot more statistical facts in its elaboration, I

shall not enter fully into the etiology (which is somewhat obscure), nor to the technique (which belongs properly to the surgeon), nor the diagnosis (which is the property of both), nor the pathology (which is the rock that divides the limpid stream of life, and the election of either channel after its passage, whether it be medical or surgical, decides in a large degree the fate of the eventful voyage). Of course the supreme comprehension of them all merges into the general field of treatment, when the battle-gauge is given and upon which depends the weal or woe of the subject.

To those painstaking, erudite, thoughtful, conscientious surgeons who bring to their task, in these monumental trials, the unimpeachable strength of purpose that wavers before no disaster, nor incriminates their courage, be the results what they may, always remembering a human life is in the balance and at the mercy of their prowess, I wish to bow in humble gratitude and sublime devoir. If there is any lofty pinnacle to which ambition towers and upon whose crest reposes its godliest hero, I believe the crown is theirs. In silent chamber and with bated breath the hovering circle waits his wondrous coming, and the canticle of joy or the deep-toned requiem, his departure.

Is it wonderful, then, that we should pause in contemplating the risks and adventures that environ every step, or stop in this debatable territory? In this connection it is interesting to note that Talamon of Paris, Guttman of Berlin, and Treves of London, affirm that from 85 to 90 per cent. of patients suffering from appendicitis recover spontaneously without the use of the knife, and Maurin and Hektoen through many hundred autopsies demonstrate the fact that from 16 to 30 per cent. of peri-appendicular adhesions, some even where perforation itself had occurred, were found with no antecedent history that tokened their existence. With this fact staring us in the face it becomes a moot question, whether the late day recognition that appendicitis is the cause of 95 per cent. of diseases invading this territory, mostly in the hands of some, demanding operation for relief, has been a blessing or a curse to humanity.

As regards its etiology, much commendation can be taken from the assurance that fæces, calcium salts, etc., are the concretions met with, rarely seeds or foreign bodies, so that we can return with renewed enjoyment to the small fruits of early life when we devoured baskets full without consequences.

The diagnosis, coupled with its subsequent prognosis, is, I take it, the foundation stone of the whole fabric, mysterious as it must be in an affection which may be acute or chronic, continuous or relapsing, with great variation of often indefinite symptoms comparable to typhoid, peritonitis, strangulation, typhilitis and others. Pain, the most prominent of all, is frequently referable to other regions, though in males (and I have not seen it mentioned) it is mostly located in the testes, and is of great intensity. It may be absent, although the most prominent symptom. The temperature is vexing; tympanites and vomiting are variable in their appearance and conflicting; acute indigestion and nephritic colic are most confounding; the pelvic derangements lend no small assistance to the general confusion; to the practiced eye the semi-shock in the acute, and the peculiar malaise in the chronic cases, accentuate its intuition.

As I said before, the condition of the viscera and appendix furnish food for controversy, even after removal.

As regards treatment, whether it shall be medical or surgical, brings the issue for yourselves to decide.

There is no question that the literature of this subject has changed rapidly during the past few years to more conservatism in the use of the knife, and personally and from individual experience I have not found the relief from appendisectomy that is claimed or I had expected. Without citation of individual cases, the results have been far from gratifying, nor do I believe the death rate as light as reports would make us believe.

I present here an extract from one of the daily journals of last week, which probably escaped the notice of even the majority of the profession, bearing mute but inglorious witness to the prevalence of its abuse:

"VICTIM OF EXPERIMENT.

Death of Norman Munro, the New York publisher. Submitted to an operation for appendicitis when it was unnecessary.

"NEW YORK, February 24.

"Norman Munro, the yachtsman and publisher, died at 6.15 o'clock to-night, at the Hoffman House. The cause of death was heart failure.

"Mr. Munro had undergone an operation for appendicitis, but it was afterward found that the patient was not suffering from the disease, and that the operation was not necessary.

"Henry, Mr. Munro's eleven-year-old son, who attended a private school at Dobbs' Ferry, had his vermiform appendix removed by Dr. Abbee on Sunday last. The boy had complained of a pain in his right side immediately after coasting. He is convalescent now.

"HAD THE SYMPTOMS.

"Mr. Munro complained of a soreness in the right side early in the week, and suspected that he had appendicitis. Under ordinary circumstances, he would not have given the matter much thought, but his symptoms being similar to those of his son led him to believe that he was suffering from the same disease. Mr. Munro became interested in the subject of appendicitis, and decided to have the appendix removed. The patient was put under the influence of ether on Friday and the operation was performed.

"No foreign substance was found in the appendix of the parent or in that of the son. There was *only a gangrenous inflammation of the appendix.** Mr. Munro recovered from the effects of the ether and conversed with his physicians half an hour after the operation.

"He seemed confident that he would pull through just as his son had done. During the night and early morning his condition grew rapidly worse. At two o'clock in the afternoon Dr. Abbe said the end was looked for any moment. His family was present when he died."

A "Victim of Experiment" was the flashing headline in large type that chronicled the catastrophe, although the operation, it appears, was performed by Dr. Abbe, one of the leading men in our ranks.

The discussion of this interesting subject cannot fail of the most salutary effect at all events, and for the sake of that great medical enlightenment that is making our age more brilliant and progressive than any of its predecessors, I hope it will continue until the veil is lifted from its present obscurity, and the refulgence of its promise becomes brighter for the ordeal it has endured.

## A CASE OF MULTIPLE NEURITIS (ALCOHOLIC).

HERMAN D. MARCUS, M. D.,* PHILADELPHIA.

The following case is interesting, owing to the markedly low temperature and its duration for 132 hours.

L. N., female, aged 34 years, was brought to the Philadelphia Hospital on December 31, 1892, in an entirely helpless condition. Her condition was as follows:

*Mental State:* Somewhat variable, seems at times rational, again wandering, mistaking those around her for former friends. Occasionally a mild muttering, delirium and hallucinations. At times believes herself at home, not recognizing her surroundings, although she has been in hospitals before.

*Motor Condition:* Complete paralysis of both legs, with the exception of being able to move left thigh from pelvis, flexing it slightly. Limbs remain in whatever position placed. No foot-drop. Great toe slightly depressed, other toes slightly curved. Has marked double hand-drop; also partial paralysis above elbow, but is able to partially elevate the arms. No facial or ocular paralysis.

*Sensory Condition:* Lower extremities are everywhere anæsthetic, showing difference in degree, mostly marked below the knees and decreasing on ascending, continuing to ensiform cartilage. Partial anæsthesia of upper extremities, decreasing from distal to proximal ends. Retardation of sensory condition in areas of anæsthesia. Handling of nerve trunks in lower extremities causes severe pain. Squeezing of feet, moving limbs and compressing muscles, or very deep pressure

* Italics are ours. Comment is unnecessary.—ED.

* Late Resident Physician at the Philadelphia Hospital.

causes severe pain. Patient is in constant fear of being touched. The hyperæsthesia on deep pressure is also imminent in upper extremities.

*Vaso-motor and Trophic Condition:* Dark, softened areas on heels. On buttocks and in lumbar region skin shows some change, and in one place the skin is broken, resembling a bed-sore. Left knee is apparently increased in size, an apparently acute atrophy. Has involuntary evacuations of bowels and yellowish green vaginal discharge.

*Treatment*: Following treatment was prescribed by Dr. Mills, the visiting physician: Bathe lower limbs once daily, for 10 minutes with hot water (115°), followed by inunction in legs of

℞ Atropine sulph..... gr. 1-6
Ung. hydrarg..... ʒv.
Lanolin..... ʒiii.
M. Use ʒ¼ twice daily.

℞ Tr. nucis vom..... mv.
Tr. digitalis..... mx.
Every 4 hours.

℞ Sodii salicyl..... gr. x.
Sodii iodid..... gr. v.
Sodii boom..... gr. v.
Aquæ..... fʒi.
Every 4 hours.

Wash eyes with Boracic acid.

Vaginal douche (bichloride mercury 1-5000) once daily followed by hot water; sand bags to arms and legs.

Two days after admission, January 21, 1883, following was noted. Almost constant delirium—mind not as clear to-day as on 31st ult. Rambles almost continually, but by a strong effort her attention can be held and she can be made to respond sensibly to some questions. Complains of pain when her limbs are moved. Anæsthesia of legs continue, paralysis of legs unchanged. Paralysis of upper extremities increased somewhat, having now no control over movements of upper arm. Her feet tend to fall into crucial position, probably due to a paralysis which is merely below knees and less marked above. Her tongue is dry and brown. No urine passed from this morning until 2 P. M. Treatment continued and ordered catheterized every four hours.

January 3d. Pulse between 115 and 120, weak and compressible; temperature about 99°; respiration shallow and hurried (about 30); still incoherent, but her mind is clearing up. On examination paralysis of extremities has increased since yesterday, so that now she is barely able to make a slight movement of elevation or adduction. Some slight increase in sensibility in both arms; knee and muscle jerks abolished.

From this on her condition became variable, at times rallying then again relapsing into her former state.

Strychina sulph. gr. $\frac{1}{30}$, was prescribed three times daily on the 9th, and to this was added whiskey ʒiii, milk fʒiii every half hour, in divided doses. The sodium mixture was discontinued. On the 12th, her temperature became subnormal, 96.6°, and from then on sank gradually until the 16th, it reached 91.2° at 7 P. M., rising to 92° at 11 P. M., and remaining at this point until her death on the 17th, at 8.30 A. M.

The temperature was taken both in the mouth and rectum, with a Hick's thermometer. This thermometer was afterwards tested and was found positively correct.

---

**The Awakening Effect of Cocaine.**

A few days ago a patient who had toothache, wishing to stop it immediately, secured nine grains of cocaine in solution, and took it into his mouth a little at a time, holding it until the accumulation of saliva become so abundant that he had to spit it out. He began using the cocaine in this manner at 5 P. M., and did not cease till 10.22 P. M., same evening. As it was then bedtime, he thought he would make sleep certain by taking 20 grains of chloral. Immediately after taking the latter drug, he took into his mouth some more cocaine and went to bed. He "swashed" the cocaine solution about in his mouth a while, then spat it out, turned on his side, and tried to go to sleep. Sleep, however, did not come; on the contrary, he did not even become drowsy. Having lain awake till midnight, and not feeling sleepy at that hour, he took, as nearly as he could tell, about *one teaspoonful* of laudanum. He went to bed again, and remained awake till three o'clock. Sleep lasted only four hours. Following this was headache.

I have often had my attention called to the fact that cocaine will keep patients awake at night when the drug is administered late in the day, but I did not know that 20 grains of chloral and a teaspoonful of laudanum would not overcome "cocaine wakefulness."—*Medical Record.*

# TRANSLATIONS.

## THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

### A PILL FOR ANÆMIA.

Prof. Edlefsen (*La Semaine Médicale*, No. 24, 1894) recommends the following pill in anæmia:

℞ Iron reduced by Hydrogen,.....
Powdered Camphor,.....āā 6 | 0 (ʒjss).
Extr. Gentian,.....5 | 0 (ʒji 1-4).
Mucilage Gum Arabic.....q. s.

Sufficient for ninety pills. Two to three pills three times a day.

He has found this formula of value both in anæmia and in chlorosis, especially when they are accompanied by cardiac disturbances as weakness and irregularity of the pulse.

### ECHINOCOCCUS CYSTS.

Prof. Bacelli (*Medicinische Nenigkeiten*, No. 15, 1894) treats echinococcus cysts by injection of a solution of sublimate. If the parasite is situated in the liver he punctures with a well sterilized trocar of a diameter of two and a half mms. the cyst at its highest point, and withdraws a moderate quantity of the fluid, following this with an injection of about twenty grams of a 1-per-cent. solution of sublimate. The tube is withdrawn and an antiseptic bandage applied. In five days the dressing is removed. The parasite is then destroyed and the subjective and objective symptoms gradually retrogress.

### SENECIO IN FUNCTIONAL AMENORRHŒA.

Dr. Murrel (*Hospitals-Tidende* No. 15, 1894) has experimented with senecio as a remedy in functional amenorrhœa on account of its being employed in England as a domestic remedy in this affection and with good results. He used a 10-per-cent. tincture of this plant in doses of an ounce four times a day. In amenorrhœa, due to general anæmia, it was inactive.

### MIGRAINE.

Dr. Freudenberg (*La Semaine Medicale*, No. 16, 1894) advises the use of the following formula in migraine:

℞ Mur. Morphine,.....0 | 01 (gr. 1-6).
Salicylate Soda,.....0 | 25 (gr. iv).
Phenacetine,.....0 | 25 (gr. iv).

Sufficient for one powder. One or two according to circumstances.

Dr. Tchetius (*ibid.*) recommends the following:

℞ Saccharine,.....0 | 01 (gr. 1-6)
Mur. Quinine,.....0 | 05 (gr. j).
Salicylate Soda.....0 | 15 (gr. ijss).
Phenacetine,.....3 | 0 (gr. xlv).

Sufficient for ten capsules. One at a dose.

### ECZEMA IN CHILDREN.

Dr. Marfan (*Hospitals-Tidende*, No. 15, 1894) distinguishes two forms of eczema in children: a seborrhœic, and a dry and patchy form. In the seborrhœic variety, in fat children, he reduces the amount of food and administers calomel, or removes the crusts and applies the following salve:

℞ Precipitated Sulphur,..... 1 | 0 (grs. xv).
Oxide Zinc..... 4 | 0 (ʒj).
Lanoline,.....
Vaseline,.....15 | 0 (ʒiv).

In the other form he applies locally:

℞ Salicylic Acid..... 0 | 05-.10 (grs. j-jss).
Starch,
Oxide Zinc.....āā 40 | (ʒ j).
Lanoline,
Vaseline.....āā 15 | 0 (ʒ jv).

### EARACHE.

In the (*Progrès Médical*, No. 16, 1894) the following is praised in earache of inflammatory origin:

℞ Powdered Menthol..... 1 | 25 (grs. xix).
Camphor..... 1 | 25 (grs. xix).
Vaseline..... 24 | 0 (ʒ vj).

Introduce a little into the ear several times a day.

### A CASE OF SORE THROAT FROM COPAIVA.

Dr. Mendel (*Le Bulletin Médical*, No. 24, 1894) had under observation a young man of twenty-two years, who, for gonorrhœa, took for several days nine capsules of copaiva a day, and then broke out with a pronounced erythematous copaiva exanthem of the ordinary appearance, and with the following throat symptoms: the soft palate, uvula, tonsils and the anterior portion of the faucial arch were very red and œdematous. The œdema of the uvula was so great that it was increased to double its

*In charge of the Translator, F. H. Pritchard, A. M., M.D.

size. The whole of the hyperemic portion was covered with numerous miliary, deep-red and vesicular prominences. This state persisted for three days, when it disappeared with the erythema.

---

FALLING OF THE HAIR AND RINGWORM.

Dr. Brocq (*Progrès Medical*, No. 16, 1894) recommends the following, both in falling of the hair and ringworm:

℞ Carbolic Acid,
Chloral,
Tinct. Iodine.....āā 100 | 0 (℥iij ℥j).

Apply once a week with a brush. Three to four times for ringworm.

---

CHOLERIFORM DIARRHŒA IN CHILDREN.

Dr. Braithwaite (*La Semaine Medicale*, No. 24, 1894) has had good results in choleriform diarrhœa in children with the following:

℞ Salicylate Soda
Sulphate Iron.....āā 0 | 60 (grs. lx ).
Neutral Pure Glycerine.. 10 | 0 (℥ ijss).
Water..... 40 | 0 (℥ jss).

A teaspoonful four times a day.

---

LOCAL ANÆSTHESIA IN EXTRACTION OF TEETH.

Dr. C. Karacatsanis (*La Semaine Medicale*, No. 24, 1894) extracts teeth without pain by first applying a strong solution of tufts of absorbent cotton to each side of the tooth, and as soon as anæsthesia is complete, the gum is separated from the tooth by means of a bistoury, and fresh pledgets of cotton are again placed into these cavities. The patient should be cautioned not to swallow his saliva, as it is more or less saturated with cocaine. Then a little of the following mixture is sprayed onto the gum:

℞ Chloroform .....25 | 0 (℥vj).
Ether .....40 | 0 (℥j ¼).
Menthol..... 3 | 0 (grs. xlv).
Mur. Cocaine .....
Essence Peppermint .....āā.. 1 | 0 (grs. xv).

The tooth is then extracted. There will be no pain with all forms of toothache, except with alveolo-dental periostitis, it is where it is impossible to subdue the pain entirely.

(This procedure would seem rather bothersome and slow. I employ a hypodermic syringe, and inject at the base of each root of the tooth to be pulled, a few drops of a 2-4 per cent. solution of cocaine with strong carbolic acid added, massage the gum for a minute on each side, and after cutting around the root, extract. In order to avoid pain the solution must be deeply injected around each root until the gum turns white. There is some danger of dangerous effects from the cocaine in such vascular tissues as the gums even with a 1-2 per cent. solution; excitement, slight delirium, paleness, faintness, coldness of the hands and feet and nervous twitchings, or even chilly sensations. I have had as many cases of untoward effects from weak as with stronger solutions. Carbolic acid acts as a preservative for the solution, and aids the action of the cocaine as has been noticed by various observers, as Gluck, Vau, etc. Atropine has been proposed as an efficient antidote to be added to the solution, but I have found it of very little or no service. The best antidotes are those vaso-dilators and cardiac stimulants as which act rapidly as nitro-glycerine and amyl nitrite. With the latter I have had no experience, but the former I can heartily recommend as worthy of confidence. I have employed it both with the solution to be injected and apart. It acts satisfactorily and at once, but only little is to be added to the injected solution, or it will spoil the action of the cocaine, much of which influence as an anæsthetic is due to its vaso-constrictive properties. I employ now a five-per-cent. solution of the cocaine, add to this watery preparation, eight drops of strong carbolic acid and five drops of a one-per-cent. solution of nitro-glycerine. I never have observed any disagreeable effects from the use of this, though without the nitro-glycerine the same preparation will give rise to trouble. Cocaine is always to be employed with caution and respected decidedly, for no one knows when it will act diasagreeably).—*Trans.*

---

**Ichthyol.**

This drug is proving itself to be one of the most valuable in the materia medica. An ointment consisting of twenty-five per cent. of ichthyol and seventy-five per cent. of lanolin, is the very best remedy for erysipelas. Ichthyol is also useful in rheumatism, in the form of an ointment consisting of equal parts of lanolin and ichthyol.—*Modern Medicine.*

# BACTERIOLOGICAL NOTES.

## THE ACTION OF LIGHT UPON THE DIPHTHERIA BACILLUS.

Ledoux-Lebard (*Archives de Med. Experimentale*) gives the results of his experiments to determine whether the influence of diffused light is destructive to germs as well as the direct rays of the sun. The conclusions reached are as follows:

1. The action of diffused light does not prevent the development of cultures of the diphtheria germs. The direct rays of the sun arrests the development of the germs. Diffused light has no bactericide power on bacteria in neutralized bouillon, but it has a marked bactericide power on the diphtheria bacilli in distilled water.

2. Diffused light kills dry cultures of diphtheria spread in thin layers in less than two days (24 hours' exposure to the light.)

3. The direct rays of sun light acts in the same manner as the diffused rays, but with greater rapidity.

4. The bactericide power of light in relation to the diphtheria bacillus is due very largely to the most highly refracted rays of the spectrum. The less refracted rays of the spectrum have little or no effect.

5. Light by virtue of its bactericide power, sterilized in less than two days the diphtheria bacilli either moist or dry, and hence is a prophylactic agent against diphtheria.

6. In diphtheritic membranes exposed to the light, many of the bacilli are reached only by the light after it has lost part of its intensity, and hence the bacteria retain their vitality and virulence much longer.

8. Light may be utilized in the disinfection of places contaminated by diphtheria.

[The results here reported are of considerable interest when the persistent nature of diphtheria is considered. There are well authenticated cases, where the disease has been contracted from rooms or clothing used by diphtheria patients, years after the disease. It has been noticed that in these cases the infected article has been kept away from the light, and if a room, it has been kept darkened. About two years ago, Dr. Sternberg brought out anew the importance of sunlight in disinfecting against Asiatic cholera. It is also well known that other bacteria are exceedingly susceptible to the influence of sunlight. These facts should be carefully considered by all physicians and the use of sunlight freely indulged in. It seems to be effective and its more extended use may render it a much more valuable prophylactic agent than it now is.—ED.]

## AN EPIDEMIC OF TYPHOID FEVER CAUSED BY MILK.

In the *Zeitschrift fur Fleisch und Milchhygiene*, Jan., 1894, there is an interesting account of an epidemic of typhoid fever in which the source of infection is very clearly shown to have been in the milk supply. An epidemic of this disease broke out in the two prisons of Strasburg in 1880, after twenty years of freedom from the disease. All of the inmates attacked had consumed milk from a particular locality. Of those who had used this milk once or more, 17 per cent. were attacked with typhoid; while out of the three hundred other persons who did not use the milk not one was attacked with the disease. The milk was used in an unsterilized condition, and when its use was stopped the epidemic came to an end.

[The continued and constantly increasing number of epidemics of typhoid fever traceable to the milk supply as the channel of infection, is a signal for more rigid inspection of dairies furnishing milk to cities and communities. The danger, as is well known, is largely confined to the contamination of the milk with water containing typhoid bacteria. This fact renders it of great importance that the sanitary conditions surrounding the dairy should be carefully inquired into, and in all cases where there is a possible chance of the water used in rinsing the milk pans,

pails, etc., being contaminated with the dejecta from typhoid patients, the milk should not be used, excepting the most careful methods of sterilization are employed. Milk is one of the best media for the multiplication of typhoid bacteria, and the fact that these bacteria produce no visible change in the milk by which their presence can be detected renders it a most favorable channel for these bacteria to gain entrance to the system. Too much care cannot be exercised to keep milk from becoming contaminated with these bacteria.—ED.]

## THE RELATION OF THE BACILLUS OF TUBERCULOSIS IN FOWLS TO THE ONE OF TUBERCULOSIS OF MAN AND OTHER MAMMALS.

Mafucci (*Zeitschrift f. Hygiene*, 1892) has studied the tuberculosis of fowls, and arrives at the following conclusions in reference to its bacillus:

1. It does not produce tuberculosis in guinea-pigs, and seldom produces general tuberculosis in rabbits.

2. On the various culture media it grows with an appearance different from that of the bacillus of mammalian tuberculosis.

3. It grows at temperatures between 35° C. and 45° C., and it is destroyed at 70° C.

4. In cultures at 45° and 50° C., the bacillus grows in long, thick, branched forms.

5. The bacillus retains, even after two years, its vegetative and pathogenic powers.

6. The destruction of the bacilli produces a substance which is poisonous for guinea-pigs and less so for adult fowls.

7. The tubercle excited by the growth of the bacillus in fowls is destitute of giant cells.

The bacillus of mammalian tuberculosis differs from that of avian tuberculosis according to Mafucci, in the following respects:

1. It produces tuberculosis in guinea-pigs and rabbits, but not in fowls.

2. Its cultures differ in appearance from those of the avian bacillus.

3. It grows at a temperature between 30° and 40° C.

4. It is destroyed at a temperature of 65° C. for one hour.

5. At temperatures between 43° and 45° C., it does not change its form in the cultures.

6. At 45° C. it loses its vegetative power in a few days.

7. The old moist cultures, after a year, are with difficulty induced to grow on fresh culture media or in the animal body.

8. The destruction of the bacilli gives rise to a substance that is poisonous for guinea-pigs, and often also for adult fowls.

9. The mammalian tubercle generally possesses giant cells.

On these grounds Mafucci holds that the bacilli of these forms of tuberculosis belong to two varieties, but he is not sure of specific differences. He is not decided as to whether man can take tuberculosis from fowls.

[It is of interest to add that the thermal death-point of the tubercle bacillus is much lower than that given by the author. —ED.]

### For Ringworm.

Iodine has been found to be one of the most effective agents for destroying the parasite upon which this disease depends. An excellent method of applying it is the following: Thoroughly cleanse the scalp with soap and water. Dry perfectly, then apply a solution of one part of pure iodine in thirty parts of flexible collodion. Renew the application each day for four days. At the end of fifteen days, remove the collodion, wash the scalp first with soap and water, then, after thoroughly removing the soap, wash with a hot solution of bichloride of mercury, 1-2500. After allowing the bichloride solution to remain in contact with the scalp for half an hour, wash with pure water, dry, and apply vaseline or zinc ointment. If necessary, repeat the application.—*Modern Medicine.*

# THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

Address care P. O. Box 843, Philadelphia, Pa.

HAROLD H. KYNETT, A. M., M. D.
Editor

RODERIC C. PENFIELD
Publisher

147-149-151 North Tenth Street, Philadelphia

**TERMS:**—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

**REMITTANCES** should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

**NOTICE TO CONTRIBUTORS:**—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JUNE 9, 1894.

## EDITORIAL.

### STYLE IN MEDICAL WRITING.

The responsibility of the editor of a medical journal is very great. It is his duty to promote the diffusion of medical knowledge, not only by his own writing, but by seeking from contributors articles that will be useful to this end, and by selecting from contemporary publications the most valuable papers, of which usually only abstracts are presented. The medical journal is a most important means of professional aid and education. It ought to help the practitioner in his daily work, and it ought to enlarge the sphere of his knowledge, and stimulate him to active thought.

But whatever information, advice and instruction are given, the manner of their presentation is of great importance. "The style is the man," it has been said, and certainly the style of a medical contribution has much to do with its ready reception. Dr. Samuel Johnson, in his memoir of the illustrious Boerhaave, wrote: "Nor was he unacquainted with the art of recommending truth by elegance, and embellishing the philosopher with polite literature; he knew but a small part of mankind will sacrifice their pleasure to their improvement, and those authors who would find many readers, must endeavor to please while they instruct." Accepting this statement from a great essayist in regard to a great physician—a physician so famous in his day that a letter sent to him from India, having on it only his name and Europe, came into his hand with reasonable promptness—we trust that a brief consideration of style in medical writing may not be unacceptable, and may prove of some value.

When the physician purposes writing a paper, let him, so far as possible, understand his subject, be reasonably certain that what he writes will be useful to the profession, and let him select a proper title for his essay. Probably there are more frequent mistakes in the last matter than in any other, causing no end of worry and trouble to those who are studying a subject, or who are preparing an

index of medical literature. Every child has a right to his own name, and so the medical contribution ought to have a distinctive title. To call the paper "A Remarkable Case," or an "Extraordinary Case," is almost meaningless, and quite mischievous. A similar criticism may be made of many other designations—designations that do not designate—applied to articles too often found in medical journals. Let the title be not only distinctive, but also brief. Then let the story be told in simple language, told as briefly as possible; "boil down," provided clearness and completeness are not sacrificed in condensation.

Of course the ordinary rules of syntax will be observed, and verbs and nouns will not be allowed to indulge in promiscuous intercourse. This may seem an unneeded direction, but it is often unheeded, for violations of it are not uncommon even in well-known writers.

Let strength be first sought rather than beauty. Richness of ornament and wealth of illustration must not be suffered to obscure thought or lead the reader away from the essential points; if these assist, make clearer and more attractive, and if spontaneous and incidental, like the rainbow that arches the waterfall telling the force of the rushing waters, very well. But let the writer never get on stilts and attempt to lift his head into the clouds. The subject and the style should correspond, and, as Voltaire has said, there is nothing more rare and difficult than to make this correspondence.

In a further consideration of the subject, we will speak more fully and plainly of the errors of composition as observed in professional writings, and of the means by which a good medical style may be be acquired.

## LECKY AND GRANT ALLEN ON PROSTITUTION.

Those who have read Lecky's "History of Morals in Europe" will recall his eloquent language in regard to the prostitute and prostitution, and his quasi-defence of this accursed form of social impurity.

This is the defence: In referring to the prostitute, he says: "Herself the supreme type of vice, she is ultimately the most efficient guardian of virtue. But for her, the unchallenged purity of countless happy homes would be polluted, and not a few who, in the pride of their untempted chastity, think of her with an indignant shudder, would have known the agony of remorse and despair."

Grant Allen, a name so well known in science and literature, in a little volume of poems recently published, entitled "*The Lower Slopes*," has one called "*Sunday-Night at Mabille*," terrible and pathetic in its picture of the suffering and sacrifice of these miserable victims of man's lust. The poem concludes with a question that probably may set those who are content to say that prostitution is a necessary evil, and that it protects the purity of countless happy homes to thinking at least:

> "One question ever rises to my lips,
> One question that I scarcely dare to breathe:—
> If woman's virtue cost so much to keep,
> Good friend, is woman's virtue worth the price?"

# ABSTRACTS.

## URTICARIA: ITS NATURE AND TREATMENT.

By Dr. Stephen Mackenzie (*British Journal of Dermatology*. March, 1894).—As here pointed out, all the phenomena concerned in the development of an attack of urticaria can be easily followed out in cases of "factitious" urticaria, and in this way: A scratch at once brings out a white streak, due to contraction of the irritated cutaneous vessels, from stimulation probably of vaso-constrictor nerves; then we have a line of redness, wider than the original white streak, caused by vascular dilatation, quasi-paralytic in character; dilatation is succeeded by stasis, transudation of serous and corpuscular elements, this constituting the "wheal." There is usually but little diapedesis of colored corpuscles, hence the white or pink color of the wheal; but this may be more marked, or rupture may occur, hence *urticaria hæmorrhagica;* or the transudation may raise the stratum lucidum and stratum corneum of the epidermis, hence *urticaria bullosa*. The whole process is reflex, so that we must have efferent nerve fibres and a centre, the latter being probably constituted by "the dense plexus of fine nerve fibres in the superficial layer of the corium." This seems to be the mode of action of *direct* irritants; but what of *urticaria ab ingestis?* Dr. Mackenzie, while admitting that it may be a *central* reflex phenomenon starting from an irritation of the gastric mucous membrane, thinks it more probable that "*something* is absorbed which circulates in the blood, and reaches the nervous plexus in the skin," a view which the author finds supported by the facts that factitious urticaria is most easily provoked in cases in which the original cause of the disease is indirect, connected with some error of diet or some idiosyncracy, and that urticaria is nearly always more or less widely and indiscriminately distributed over the cutaneous surface, and not in the territory of any definite nervous supply—entirely unlike the distribution of zoster.

The mucous membranes are sometimes affected in urticaria; that of the mouth may be seen to be swollen; there may be asthma or dyspnœa, from urticarial swelling in larynx or bronchioles; or hæmatemesis from an urticarial condition of the gastric mucosa. On the skin, also, the urticarial papule may pass into an inflammatory papule, when we have the so-called *lichen urticatus*.

Dr. Mackenzie refers to some of the less common causes of urticaria, particularly to the association of the disease with hydatids; it sometimes follows pregnancy; in one case it occurred fifteen times in succession after the passing of a uterine sound; it may occur during menstruation or pregnancy, or from simple emotion.

After giving some details of a few very unusual cases, the author passes on to discuss treatment under two heads—removal of cause, and mitigation of effects. Local irritations must be removed—animal parasites, irritating clothing, unusual articles of diet. In acute cases very mild measures suffice—a simple and bland diet, a stomachic, and a warm bath. In more obstinate cases the skin must be soothed by a nightly warm bath (for fifteen minutes) containing starch or potassa sulphurata (2 ounces to 30 gallons of water), followed by a rubbing with a lotion of carbolic acid and glycerine, or smeared with a 2 per cent. salicylic vaseline. Ointments of carbolic acid and salicylic acid are often useful. Menthol is not of much service. In the severe form much good often results from swathing the affected parts with lint soaked in glycerine of lead (1 ounce to 20 of water). Internally the author has found the greatest benefit from antipyrine (20 or 30 grains at bed-time), which may be repeated each night in chronic cases. Salicylates, atropine, bromide of potassium (with or without atropine) are all recommended. In gouty cases, or when there is defective action of the kidneys with lessened excretion of urea, colchicum has been found valuable. Pilocarpine also is sometimes found to be useful.

### Odorless Iodoform.

Iodoform, it is said, can have its disreputable odor successfully masked in the following combination: Iodoform, powdered benzoin, powdered cinchona, and magnesium carbonate, equal parts, and a little oil of eucalyptus. The formula is credited to Lucas-Championniere.—*Ex.*

# SOCIETY REPORTS.

## THE LOUISVILLE MEDICO-CHIRURGICAL SOCIETY.

*March 9, 1894.*

STENOGRAPHICALLY REPORTED BY C. C. MAPES.

### MICROCEPHALUS.

DR. A. M. VANCE: This patient is three years of age, and my object in presenting the case is to make a continued report. It is a typical case of microcephalus. On the fifth of April last, I opened one side of the head, and on the sixteenth of the following June operated upon the other side. It has now been nearly a year since the first operation, and there has been practically no improvement in the child's condition. There was no unfavorable symptom following either operation; the child left the hospital each time on about the sixth day, and both wounds healed perfectly. One rather pecul ar feature about this case is that the child has never been induced to partake of anything in the way of food except milk, and that is taken from a bottle. The mother reports that she has never been able to persuade the child to take any solid food.

As I stated at a previous meeting of this Society, I have come to the conclusion that craniectomy for microcephalus is an unjustifiable operation. This conclusion has been reached from my observations in the two cases upon which I have operated, and from reports of others who have done the operation.

#### DISCUSSION.

DR. C. SKINNER: What result was noticed from the operation?

DR. A. M. VANCE: At the time I performed the first operation upon this child, I felt quite encouraged, as there seemed to be an indication of improvement in intelligence, but now after nearly twelve months have elapsed, I fail to see any improvement whatever. Epileptic seizures still occur; they have been somewhat modified under the administration of bromides, but as soon as the bromides are withdrawn the attacks return.

DR. WILLIAM CHEATHAM: I looked at this child's eyes, and from the restlessness exhibited to-night, may be imagined the difficulty experienced in making an ophthalmoscopic examination; I was finally able to get a reasonably satisfactory view, and am satisfied that there is atrophy of both optic nerves. The mother states to-night that she thinks there is some vision. She bases this statement upon the fact that when the child is lying quietly on the bed, and she is moving about the room, the child seems to recognize her presence as she comes closer to it. I doubt if there is any vision at all, as we know there are other means by which a child can recognize its mother's presence. The optic nerves are perfectly white.

### TRAUMATIC ANEURISM.

DR. A. M. VANCE: At the annual meeting of this Society, last may, Dr. Turner Anderson exhibited a patient having traumatic aneurism of the femoral artery. I present the patient now to show the result of removal of the aneurism by dissection, and also show the specimen.

The history of the case is that the patient, about two and a half years ago, while working with a hammer and chisel upon a piece of steel, a piece of the hammer or steel flew off, penetrating his thigh. The bleeding was quite excessive, but he was seen soon afterward by his physician and the hemorrhage stopped by a compress. Subsequently the aneurism developed. On September 19th, 1893, I dissected out the aneurism carefully, and exhibit both the patient and the specimen. He has had a pretty rough time of it. Both the vein and artery were involved—aneurism of the femoral artery and a varix condition of the large vein in that situation—requiring a very careful dissection. I dissected the whole mass and applied a ligature above and below. On the twenty-third day after the operation he had secondary hemorrhage due to the fact that the femoral was double, commencing just above the aneurismal sac, and the ligature was applied so near the bifurcation that it was not permanent. There was no swelling of the foot on that side due to the ligation. It is evident in this case that collateral circulation had already been established. It was necessary to make a long incision to get sufficient space in which to work, and altogether the operation was a very difficult and tedious one. I believe complete dissection of the aneurismal sac is the best treatment of this condition, and the result in this case shows the wisdom of it.

#### DISCUSSION.

DR. A. M. GARTLEDGE: I agree that the probable cause of the secondary hemorrhage was that the ligature was applied so close to the bifurcation of the artery. This is evident from the fact that there was a little leakage on several occasions. I also agree that there is only one way to treat these aneurisms and that is to completely dissect out the sac.

Dr. T. L. McDermott read an essay on

APPENDICITIS FROM A MEDICAL STANDPOINT.

(See page 813)

DISCUSSION

DR. A. M. VANCE: I agree with McDermott that appendicitis is one of the most interesting subjects before the medical and surgical world at the present time. The question arises in each case whether it is a case for the physician or surgeon, and I must say at the beginning that I think one of the greatest faults in the outcome of a great many of these cases is that the doctor does not call the surgeon sufficiently early. I have operated for appendicitis ten times and lost four patients. Of the four patients that died, two were the subjects of general peritonitis, and were practically moribund before the operation was performed. In one case the first symptoms had appeared about eighteen hours before; the other, about three days. I believe if both had been operated upon at the very onset, they would have been saved. Of the other two cases, one was in active sepsis at the time of the operation; Dr. Bailey and several of the other members present witnessed the operation. The man died from sepsis, without the paresis of the bowel that we nearly always see, because the bowels moved freely and there was no tympanites at any time. I believe firmly that unless a case of supposed appendicitis is practically well in twenty-four hours from the first symptom that attracts attention, an operation should be performed. It is my opinion that this will be the treatment hereafter. Surgical statistics are positive; while statistics from a medical standpoint are of no value whatever; because the ordinary medical man (without operation) cannot tell absolutely whether his patient had appendicitis or not. In proof of that fact, Richardson has gone over the death statistics of Boston, Cambridge, and various other cities in that section, and the facts show that the death rate in adult males from *peritonitis* in the last decade has been very great. What else in the young male can produce peritonitis except appendicitis, excluding traumatism? I am appointed to write a paper upon the "Determination for Operation in Appendicitis" for the next meeting of the State (Kentucky) Medical Society, and I believe the whole subject can be covered in one line—"Diagnosis; then Operation."

DR. WM. BAILEY: I do not feel that I can do the subject under discussion justice; in fact I do not know that I have any very thorough convictions about it. There is great difficulty in making the diagnosis of appendicitis. I am not sure about the many cases claimed as having been cured by the physician really having been appendicitis. There is great difficulty sometimes in differentiating appendicitis from what we used to call typhlitis and perityphlitis; those cases in which the appendix is not involved. I believe that a large number of them get well even under the care of the ordinary physician. But in cases of undoubted appendicitis I am doubtful of recovery without surgical procedure, and I think the greatest difficulty is in making that differential diagnosis. Great stress is laid upon the McBurney point, a prominence midway between the anterior superior spinous process of the ilium and the umbilicus. It is evident at first sight that this cannot avail because of displacement of the appendix. There cannot be a stated point of prominence, if, as has been proven by operations, the appendix is displaced, and I doubt if, the appendix being behind or external to the cæcum, there would be a point of prominence. There is, however, one important diagnostic point that occurs to me, and that is tension of the muscle on that side, even before a tumor can be recognized or there is any marked tenderness. I do not believe that we can recognize a tumor as soon as an operation ought to be performed. I do not think we ought necessarily to wait for a tumor. I think the impression made by perforation would be manifested by the impression made on the pulse. Now, in the case Dr. Vance speaks of, the heart was decidedly impressed; and, while the operation was well and quickly performed, I do not think recovery could have been possible under any circumstances. There was a large abscess, from which very offensive pus was removed, and the man was evidently under the influence of sepsis before the operation. He did not die from the operation or its effect. I doubt if he died as soon as he would have done if the operation had not been performed. The patient was sick only three days; the surgeon was called on Friday, operated on Saturday, and the boy died twenty-four hours afterward. The heart could not be maintained, the usual remedies made no impression upon it whatsoever. Of course we have all seen cases of so-called typhlitis, accumulations of fecal matter in the cæcum, etc., give rise to symptoms similar to those in appendicitis. The tumor may even be more marked than in an ordinary case of appendicitis, and I think the great difficulty is in the physician determining whether it is appendicitis or not. I would make it largely a question as to surgical interference, whether or not we can demonstrate that it is a case of appendicitis. I have seen a number of cases of so-called appendicitis—I regarded them as such—recover under medical treatment. In my observation of thirty or thirty-five years, in my own practice I have never had occasion to resort to surgical measures in the

DR. WM. BAILEY: I do not feel that I can do the subject under discussion justice; in fact I do not know that I have any very thorough convictions about it. There is great difficulty in making the diagnosis of appendicitis. I am not sure about the many cases claimed as having been cured by the physician really having been appendicitis. There is great difficulty sometimes in differentiating appendicitis from what we used to call typhlitis and perityphlitis; those cases in which the appendix is not involved. I believe that a large number of them get well even under the care of the ordinary physician. But in cases of undoubted appendicitis I am doubtful of recovery without surgical procedure, and I think the greatest difficulty is in making that differential diagnosis. Great stress is laid upon the McBurney point, a prominence midway between the anterior superior spinous process of the ilium and the umbilicus. It is evident at first sight that this cannot avail because of displacement of the appendix. There cannot be a stated point of prominence, if, as has been proven by operations, the appendix is displaced, and I doubt if, the appendix being behind or external to the cæcum, there would be a point of prominence. There is, however, one important diagnostic point that occurs to me, and that is tension of the muscle on that side, even before a tumor can be recognized or there is any marked tenderness. I do not believe that we can recognize a tumor as soon as an operation ought to be performed. I do not think we ought necessarily to wait for a tumor. I think the impression made by perforation would be manifested by the impression made on the pulse. Now, in the case Dr. Vance speaks of, the heart was decidedly impressed; and, while the operation was well and quickly performed, I do not think recovery could have been possible under any circumstances. There was a large abscess, from which very offensive pus was removed, and the man was evidently under the influence of sepsis before the operation. He did not die from the operation or its effect. I doubt if he died as soon as he would have done if the operation had not been performed. The patient was sick only three days; the surgeon was called on Friday, operated on Saturday, and the boy died twenty-four hours afterward. The heart could not be maintained, the usual remedies made no impression upon it whatsoever. Of course we have all seen cases of so-called typhlitis, accumulations of fecal matter in the cæcum, etc., give rise to symptoms similar to those in appendicitis. The tumor may even be more marked than in an ordinary case of appendicitis, and I think the great difficulty is in the physician determining whether it is appendicitis or not. I would make it largely a question as to surgical interference, whether or not we can demonstrate that it is a case of appendicitis. I have seen a number of cases of so-called appendicitis—I regarded them as such—recover under medical treatment. In my observation of thirty or thirty-five years, in my own practice I have never had occasion to resort to surgical measures in the

treatment of so-called appendicitis, and have never had a case die. Perhaps they were simply cases involving the cæcum, yet local peritonitis developed in some cases. Frequently I have seen marked tumor in the appendicular region with constitutional impression, elevation of temperature, quickened pulse, tenderness on pressure and rigidity of the muscle, etc. Yet I do not know whether they were appendicitis or not.

DR. J. G. CECIL: I have no very pronounced opinion in regard to appendicitis because my individual experience in that direction is very limited. Like my friend, Prof. Bailey, I have never seen a case in my own practice that I can say positively was appendicitis. Those cases that I thought were appendicitis have recovered without operation. In the cases that I have seen, operation has not been indicated; the cases that I had every reason to believe were appendicitis have gotten well without it. However, I recognize the fact, which is established beyond any reasonable doubt, that many of these cases do necessarily require an operation to save them. Any opinion of a given case that I might have would, of course, be based upon the diagnosis of the case. My judgment as to operation would depend upon the diagnosis, and I am prepared to say if I were called to see a case of supposed appendicitis and could make out from the symptoms and history of the case that suppuration or perforation had occurred, I would not hesitate a moment in advising an operation. Until this feature could be substantiated I should be inclined to hesitate. I do not believe that every case of *supposed appendicitis* requires operation at once. It all depends upon the diagnosis. If a case of suppurative appendicitis is established beyond question, then an operation is demanded; but neither the surgeon nor the physician, to my mind, has yet given us a schedule of diagnostic points which will enable us to say one way or the other just what is the proper procedure. Notwithstanding the very pronounced and decided views taken by both sides, I am still "on the fence."

DR. J. L. HOWARD: I certainly think that appendicitis is a surgical disease so soon as the diagnosis is made, and should be operated upon without further delay. I have been unfortunate enough in the last year to have had two cases of appendicitis, one operated upon the other not. The first case was a young man whom several of the Fellows will doubtless remember. He was taken on Wednesday with pain in the right iliac region; there was no tumor, the pulse was not accelerated, and the temperature up to the time collapse came on, did not exceed 101° F. The next morning (Thursday) I made diagnosis of appendicitis; I did not pay any attention to McBurney's point, because I do not see how we can expect to have any defined point in an organ as large as the cæcum, when it varies so much in shape from distension, etc. The diagnosis I made was catrrhal appendicitis, which I shall always regret because I think it is very misleading and we should not classify appendicitis as catarrhal. It does not matter what the nature of the inflammation in appendicitis is, it should be operated upon. I called in a surgeon immediately who agreed with me in the diagnosis, but as the patient had a pulse of 74 and was getting along so nicely, he advised waiting a day or two before operating. The case went on until Saturday night, when suddenly symptoms of general peritonitis set in, perforation evidently having taken place. Owing to the time of night I was unable to get a surgeon immediately, and operation was not performed until the next day. The patient was in collapse at the time.. Right here is an important point: If I were a surgeon I would never operate upon a patient in collapse. The operation was quickly completed and the patient died a short time afterward. The other case had a similar history, and showed about the same condition. In both cases the appendix was almost entirely destroyed. In the last case it was very hard to find the appendix, only a small portion of it being left, and the cavity was filled with pus.

DR. TURNER ANDERSON: I have expressed myself so often upon this subject before this Society that I feel I have little to add to what I have already said on the question of appendicitis. I can talk only about my own experience, what I have seen, etc., and perhaps there will be little interest attached to it. I say now, as I have on a great many occasions, that the reports and specimens that have been presented at different times have not changed my views in regard to this trouble.

The first case of appendicitis I saw was in 1866, it was then called perityphlitis. That man is alive and well to-day. The name "appendicitis" was not known at that time, the nomenclature has been changed since. From that time to the present I will say that I have never seen a case not operated upon which terminated in abscess or in death. Within four months of the present time I saw a little girl ill with abdominal pain, having a tumor as large as a man's fist immediately beneath the McBurney point, that went on with dysenteric symptoms until it looked very much like a case in which an abscess had formed, and that operation would be nothing more than opening an abscess. Dr. W. O. Roberts saw the case with me. The child's pulse was good, inspection of the abdomen showed the tumor—it was not neces-

sary to palpate as it could be plainly seen. We concluded to wait until the next day, and the day following we waited again. There was a sudden subsidence of the pain and discomfort, the tumor entirely disappeared and the little girl made a perfect recovery. Her temperature on several occasions was 103° F.

Nine months ago I was asked to see a case with Dr. Roberts, a little Jewish child. The patient was lying in bed, with the leg flexed and all the evidences of perityplitis abscess, tumor quite large. The mother strenuously objected to any operative procedure, and I told her that I belirved the child would get well if let alone. I was not sent for in consultation at request of Dr. Roberts, but was asked by the people. I believed that the child would get well and wouid not force the operation. That child is running about now, going to school.

From 1866, when I saw my first case, up to the present time I have not seen a case that has terminated in suppuration, nor terminated in death, which was not operated upon. That is a queer personal experience. I do not mean to criticise the surgeons on the subject, nor their operative procedures; I simply state facts.

Some months ago I thought Dr. Cartledge had advanced views which were entitled to most important consideration. He suggested that the appendix was an organ which had some special way, when attacked with catarrhal inflammation, of getting rid of that inflammation by discharging into the cæcum—some special way which was not understood. I thought it might be possible for the appendix to fill up with a semi-liquid material and form a tumor without closing the proximal extremity of it. I thought there might be something in what Dr. Cartledge said, and the course he suggested might be pursued, which would explain recovery of some of the cases treated medically. I was much surprised at the last meeting of this society, when Dr. Cartledge, without prefacing anything he had previously said on the subject, exhibited a specimen of an appendix he had removed (the man having presented symptoms of recurrent appendicitis) calling attention to stenosis of the proximal extremity of it. I could not see anything the matter with it. I could not see anything abnormal about it simply from an occular inspection. There had been no perforation of that specimen. So that my idea is that it was a case of catarrhal appendicitis, where the tumor had discharged into the caecum, the accumulation having been gotten rid of in that way. Though Dr. Cartledge declared there was no such thing as "catarrhal appendicitis," he presented an appendix which, so far as I could see, had nothing the matter with it. It shows how difficult it is for us to arrive at a satisfactory classification, or to intelligently discuss this subject from a pathological standpoint. Therefore, discussion of the subject from a clinical standpoint at the present time is the only standpoint from which we can get any special information. I believe if I were called upon to demonstrate whether an operation should be performed for appendicitis in an individual I had a great deal of interest in, I would decide in the negative. I have seen a great many cases of appendicitis; have been present at the operation; have seen the appendix removed and have not seen positive evidence of disease, nor evidence sufficient, in my judgment, to justify operation. And, as I say, I have not seen a case terminate fatally which was not subjected to operation.

There is one case to which I want to call attention without mentioning any names, where I think a man would have had better chances of life if he had not been operated upon. He was a beer drinker. Obese, flabby, had a weak heart, a depressed nervous system, and perhaps kidney trouble in addition. I think that man would have stood a much better chance to have gotten well if he had been let alone. He died soon after the operation, and so far as I am able to offer an opinion, there was nothing in the appendix that could have caused the symptoms under which he was laboring at time of the operation. I believe that operations for appendicitis are being performed too frequently; that there is entirely too much being done in this line. This thing of talking about recurrent attacks of appendicitis and operation to prevent the dangers that may come, I think is a grave mistake, and I believe it is a great deal better to trust to our old methods of treatment in these cases than it is to open the belly upon the slightest evidence of pain or distension. There are a great many people who suffer from constipation, indigestion, flatulency, etc., which might cause the same amount of pain and tenderness, and I believe that many mistakes are made when the belly is opened. It is a very difficult question, as the essayist has said, to determine what the condition is; I believe in a great many cases those conditions which were supposed to have been the cause of the disease are largely *post-mortem*.

DR. E. R. PALMER: I would like to ask Dr. Vance the final outcome of the case (Mr. W.) he operated upon some time ago for appendicitis?

DR. A. M. VANCE: The history of that case was that the man had suffered several attacks of severe pain, and everything pointed to appendicitis. At the operation, from a macroscopical examination of the appendix, I did not think it was diseased, but the microscope revealed that it was in a state of

active inflammation. The man has had a similar seizure since the operation, and there must, of course, be something outside of the appendix as a causative agent. He is a very nervous, hysterical man.

DR. A. M. CARTLEDGE: Did Dr. Anderson take the trouble to examine two other specimens I exhibited at the last meeting of this Society? He only mentions one. If he had examined the other specimens he would have observed a pathological condition certainly demanding operation. One was a large perforated appendix, and the other a necrotic stump of appendix with fecal matter pouring in the surrounding abscess.

DR. TURNER ANDERSON: I think those specimens were undergoing a form of resolution which may be common in tumor cases. Very recently I was asked to see a woman where I believe such a condition existed.

DR. A. M. VANCE: Did not Dr. Anderson see pus in the belly of a case of appendicitis upon which I operated in his presenee some time ago?

DR. TURNER ANDERSON: I do not remember to have seen any pus; there may have been the remains of a hematocele, but I believe the appendix was in a healthy condition. I did not examine the specimen Dr. Cartledge presented with a great deal of care, but I could see no pus or anything else to indicate disease. I do not know whether rupture had occurred or not, or whether there had been an inflammatory exudate outside which had marked the effusion of pus. I asked him where the morbific evidences were, and he said I would have to take his statement that the appendix had contained liquid feces, etc. I told him that I would accept the fact that it was a case of appendicitis, and asked him to point out the point of stenosis which was supposed to be near the proximal extremity. He made the attempt, but I was unable to see anything wrong with it.

DR. J. L. HOWARD: How many cases has Dr. Anderson seen in which he has noted the formation of pus, or an abscess causing general peritonitis?

DR. TURNER ANDERSON: I have never seen a case terminating in suppuration or death.

DR. C. SKINNER: I do not know just where I do stand on this subject. It strikes me, though, that since the matter has been brought up, it has about resolved itself into a factional discussion. I am going to claim to belong to both sides. Some of you know that I sometimes do work in this line, and I also practice medicine. It would be a very hard matter to reconcile the statements made by the different speakers, but when we hear the statement from such men as Drs. Bailey and Anderson, who have been thirty-five and twenty-eight years respectively in active practice, that operation in the majority of these cases is not required, it would seem that their views are entitled to mature consideration. I am going to bore you with the recitation of two cases; one operated upon followed by recovery, the other not operated upon also got well.

The first case was a very thin woman, seen by me three years ago at the city hospital. She was about thirty years of age, and one peculiar feature was that she had no teeth. She was suffering at the time from what appeared to be an undoubted attack of appendicitis. She was carefully watched by both myself and the Interne. There was an exquisitely tender spot in the right side of the abdomen at about the McBurney point. In the first attack, under the application of cloths wrung from hot water to which had been added a little turpentine, all tenderness disappeared. I kept her under observation for two months, and in this time she had three attacks of this sort, and I pronounced the trouble fermentative indigestion. The woman, on account of the absence of teeth, was not able to masticate her food at all. As stated, diagnosis had previously been made of appendicitis. This woman became apparently well, but I left her in the ward at the expiration of my term of service. I did not operate upon her. My successor took this patient out of the hospital—some repairs were being made and it was deemed wise not to operate in the hospital—and removing her to one of the Infirmaries, operated for appendicitis. I was not present at the operation, and did not see the patient until several days afterward. From those who did see the operation I learned that the appendix was in a normal condition. Shortly after the operation and before the stitches were removed, she had another attack of the same character, and came very near dying. She finally recovered from the effects of the operation and went to Indiana. Last year, during my service at the City Hospital, this woman turned up again. She came into the ward and said that she had been having those attacks right along since the operation. I then secured for her a set of false teeth, and after several trials we succeeded in getting a set that would fit. Then arose the difficulty of getting her to properly masticate her food with the new teeth. I practiced the lavage treatment of the stomach, and up to the time I left the ward no more attacks had occurred. In about a month absolutely all evidence of trouble ceased.

No. 2.—In June I was called to see a young woman in this city who had always been the perfect picture of health, and another physician, her relative, had attended her for three days when I was called. She was taken ill very suddenly with intense pain in the right

iliac region. At the time I saw her she had been given a cathartic, the bowels h ad moved freely, but there was no cessation of pain. The pain increased and though the bowels were still open the temperature ran up, reaching 106° F., with a tumor in the right iliac region seemingly the size of two fists. I recognized the gravity of the case and called Dr. Bailey in consultation at once. I had already planned out a line of medical treatment—the use of opium and hot applications. This woman went along for two weeks under that treatment, making a good recovery, and is well now. Here was a case of unmistakable appendicitis which recovered under full doses of opium, keeping the patient sleeping nearly all the time, and the use of hot applications, changing these every thirty minutes. The tumor disappeared and in two weeks she was up.

I hardly know where I stand on a question of this sort. I believe, though, where there are unmistakable signs of pus, or any evidences of perforation, that operation is justifiable.

[Continued in issue of June 16th.]

## CINCINNATI OBSTETRICAL SOCIETY.

### OFFICIAL REPORT.

*Meeting of February 22, 1894.*

Dr. E. G. Zinke exhibited the following specimens:

FIBRO-CYSTIC TUMOR OF THE UTERUS.

This specimen was removed from a patient who presented herself at the German Hospital a week ago last Tuesday, the 13th of this month:

Mrs.—, age forty-seven, very much emaciated, which made the presence of an abdominal tumor quite perceptive; mother of but one child, born twenty years ago. Never had a miscarriage. Has not felt well since the birth of the child. The first appearance of the tumor was noted some eighteen years ago, having grown steadily until it attained its present large size, filling up, as it did, the whole of the abdominal cavity. The tumor was fluctuant two inches above the symphysis, and absolutely solid below that point. The sold mass of the tumor filled out completely the pelvic cavity, so that the os externum could notbe reached except by forcing the finger high up between the growth and the symphysis. The diagnosis was a fibro-cystic tumor, either of the uterus or ovary, or a fibroid tumor of the uterus complicated by a large ovarian cyst. The patient was very weak; her temperature ran up every afternoon to 101°; pulse 130, wiry and compressible. It was evident from her general condition that her days on earth were few if not relieved from this growth. Her physical condition was such that even operative interference promised very little. However, the family, as well as the patient herself, embraced the only opportunity that was left. She was operated upon the 16th of this month. A free incision was made in the median line, probably seven to eight inches in length. A cyst universally adherent presented itself. The adhesions were very strong, firm and exceeding difficult of separation. The tumor was punctured with a trocar, with a view of emptying it and in this way facilitate removal. A large amount of chocolate-colored fluid escaped. After reducing the tumor in size, I found it impossible to separate the adhesions, and most of them had to be ligated and severed by the knife. After the tumor was freed anteriorly, and from the omentum and intestines above, I attempted to get my hand behind the tumor to separate the adhesion In this attempt I broke through the cyst, and its contents freely flooded all of the abdominal viscera. After a good deal of hard and persistent work I succeeded in eventrating the growth, but it proved absolutely impossible to liberate the solid portion from the pelvic cavity, and was obliged to fix this large and solid mass in the abdominal wound, abandoning the idea of liberating the tumor entirely. A clamp was put around it and the tumor transfixed. About twenty hypodermic injections of whiskey, as well as a transfusion of sterilized salt water solution, had to be made to keep the patient alive long enough to get her off the table. The following morning the temperature was 99°, the pulse 130.

She died of exhaustion forty-eight hours after the operation. The fluid removed from the cyst consisted of degenerated fat globules; no streptococci could be discovered. The tumor had its origin in the posterior wall of the uterus.

---

TOTAL VAGINAL HYSTERECTOMY OF A FIVE MONTHS' PREGNANT UTERUS FOR CARCINOMA COLLI.

The other specimen which I would present this evening is the contents of the uterus, removed after I had extirpated the uterus per vaginam. The patient was a woman, age thirty-nine, the mother of a large family, the youngest of which was only four years of age. The patient was referred to me by Dr. Koehler, of this city, who had made a diagnosis of epithelioma of the cervix. Upon examination I confirmed his diagnosis, and we determined to make a vaginal hysterectomy. There was some suspicion at the time that this woman was pregnant, but upon digital examination I could not feel the fundus of the uterus. She is a very large, heavy, fat woman, and I expressed it as my opinion that she was not pregnant, although I did not preclude the possibility of it. She had bled constantly, because of the cauliflower excrescences in the cervix. I operated a week ago last Saturday, at the German Hospital. After I had separated the cervix from its attachments I tried to pull the organ down. I could not feel the end of the uterus, and the organ was quite soft, and I recognized the fact that she was pregnant. Of course there was no use of hesitating any longer, and I had to put on the clamps and remove the whole pregnant uterus. I did not apply any ligatures. After we removed the organ we incised it and removed a four months fetus from it. The patient is now virtually well. She did not suffer from shock any more than a woman ordinarily does from an operation of this kind. It is highly probable that, had I known of the existence of pregnancy, we would not have operated upon this woman, and yet had we done so we would certainly have placed her life in great jeopardy, because the result would have been inevitable. Had this woman advanced to full term we would have been obliged to have made Cæsarean section, and the disease by that time would have made such inroads as to preclude the likelihood of a recovery. So, notwithstanding I did this without being in the possession of all the facts of the case, I have done the very best thing that could possibly have been done for her. She has not had an untoward symptom at any time.

The first specimen presented itself to me in this way: Had I been politic, or permitted policy to actuate my conduct in the case, I should have preferred to send her home without an operation, but it appeared to me to be an act of cowardice not to make an attempt; for, although the appearances are unfavorable, it seemed to me to be my duty to present the case to her friends and leave it to them to refuse or accept.

---

**The Electrical Treatment of Infantile Paralysis.**

Dr. Lewis Jones, at the London Medical Society, March 5 (*The Lancet*, March 10th, 1893) read a paper on the above subject based upon an extended experience in the Electrical Department of St. Bartholomew's. His conclusions are that prolonged electrical treatment would do much good in nearly all cases, providing that the children were young and that not more than three years had elapsed since the incidence of the disease. He assumes that in many cases a considerable number of muscular fibres, damaged perhaps, but not destroyed, remain in the affected muscles, and that the motor or ganglion cells in the anterior horn of the spinal cord, which supply the muscles have a considerable vertical space and many of these might thus escape destruction. His purpose appears to be to bring the fibres which may happen to remain to the highest possible state of nutrition by applying treatment directly to them; if he expects to improve either directly or indirectly the cell in the cord he makes no suggestion of it. He divides the cases into two types.

The electrical treatment is to be applied twice a week, and the affected limbs bathed in warm water and well rubbed every night. Any form of electricity is of value which will stimulate living tissues, but if it has to be placed in the hands of the mother, faradism is best because most easily managed. Care should be taken not to frighten the child by sudden shocks. He summarizes as follows; 1. It is important in every case of infantile paralysis which has lasted for more than four weeks to try electrical treatment for six months or a year, if necessary. 2. It is exceptional for the muscles to be so completely destroyed as to have no functional fibres left. 3. A great development of these remaining fibres might be gained by a preseverering stimulation of them by electricity. 4. When the electrical reaction is entirely absent or reduced to the lowest point some improvement may still be hoped for.

# THE LIBRARY TABLE.

## BOOK REVIEWS.

*An American Text-book of the Diseases of Children*, including special chapters on essential surgical subjects: diseases of the eye, ear, nose, and throat; diseases of the skin; and on the diet, hygiene, and general management of children. By American teachers. Edited by Louis Starr, M. D., assisted by Thomas S. Wescott, M. D. Published by W. B. Saunders, 1894.

The diseases of children, though a part of the study of general medicine, form a chapter in the healing art which is more or less distinct and separate from the rest of the subject. The symptoms, the cry, the cough, the expression of the face, all demand a special interpretation in babies which is not furnished by our knowledge of the diseases of adult life. For better understanding of the subject, therefore, we naturally look to the works of eminent authors; and since the tendency of the day is toward specialties, we rightfully expect from the pens of these specialists a terseness and exactness of statements which we can rely upon in any emergency.

The present volume is really an encyclopædia upon the diseases of children, embracing all that has proved valuable knowledge in the hands of no less than sixty-three American teachers, including the most eminent authorities on their respective subjects that the country has produced, among whom may be mentioned such names as Pepper, Ashurst, Da Costa, Gray, Hirst, Osler, White, Griffith, Deaver, and a host of other men holding prominent teaching positions in the leading medical colleges of America.

The work is edited in a masterly manner by Dr. Louis Starr, of Philadelphia, who has, in addition contributed chapters upon the discussion of "*Simple Atrophy*," "Measles," and the "Clinical Investigation of Disease and the General Management of Children."

Among the more strongly written chapters may be mentioned those of Osler's article upon tuberculosis, in which the most practical points are as to prophylaxis and treatment. The former consists in the destruction of the sputa and the disinfection of milk by boiling, when the source of the milk is of doubtful purity. The treatment he resolves into three essentials—sunshine and fresh air, nourishing food, and reconstructive tonics, such as cod liver oil, hypophosphites and creasote.

Starr's article on "Measles" is to the point, and at the same time written in an easy, agreeable style. The chapter on "*Simple Atrophy*" is condensed into five pages.

Among the other attractively written parts of the book may be mentioned the contributions of Ashnrst on "*Appendicitis*" and "*Intussusception*," respectively. The nine chapters by Chas. K. Mills, especially those upon "*Headache*" and "*Insanity*," and of William White's "*Vesical Calculus*" and *Gonorrhœa*."

The work is printed on excellent paper in large, clear type, and is profusely illustrated; and in every respect deserves a first place in the physician's library. W. H. H.

*The Standard Dictionary.*

The announcement is made of the completion of Volume 1, of the Funk & Wagner Standard Dictionary, and the statement is made that the second volume will be completed during the year 1894. An examination of the volume shows that it will meet the daily needs of the reader, perhaps better than any other dictionary in existence. It certainly will prove of invaluable service to all English students. It is the result of more than four years of constant labor by two hundred and forty-seven office editors and specialists, assisted by hundreds of other men and women. The estimated cost of the dictionary is over one million of dollars. The vocabulary is extraordinarily rich and full. The number of words and terms found in the Standard Dictionary is nearly three hundred thousand.

There are certain distinguishing characteristics of the work which greatly add to its value. For instance, in definitions of words, the most common meaning is given first; that is, preference is given to the order of usage, rather than the historical order generally followed in other dictionaries. The etymology is placed *after* the definition; a great convenience for ready reference. In the pronunciation of words, the scientific alphabet prepared and recommended by the American Philological Association is used. The quotations in the work, are located by book, page and edition from which the quotation has been taken. By a simple and comprehensive system, the best judgment of the English speaking world on all disputed points of pronunciation and spelling is clearly indicated to the reader. A systematic treatment of the compounding of words has been thoroughly undertaken. Obsolete, foreign, dialectic and slang words are given places only if likely to be sought for in a general English dictionary. Great care and labor has been bestowed upon every page and every article. Specialists in every department of science and learning have supplemented the learning of the editor-in-chief and his immediate associates.

A marked feature of the dictionary is found in the magnificent illustrations especially prepared for the work. For instance, under the heads of Architecture, Coins, Fowls,—fine illustrative plates have been prepared which greatly aid the reader, and are in themselves an education on the subject treated. Under the word decorations a handsome colored double plate shows the various decorations of honor used in the world. Under the title of Flag, the various flags of the world are exhibited, under the title of Gem,

a remarkable plate is given, showing the various colors and forms of the leading precious stones.

In technical and scientific matters, the Dictionary is far in advance of any other published. It is without doubt the best working dictionary that has yet appeared. Its scope appears to be almost unlimited, and the work is as complete and reliable as possible. It is a great monument of exact scholarship; and it is not too great praise to say it is the best of English dictionaries. We unhesitatingly commend it to our readers as the Standard dictionary of the English language. It will be published in a single volume, as well as the two-volume edition. A. G. K.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D., AND SAMUEL M. WILSON, M. D.

---

THE ANNALS OF GYNÆCOLOGY AND PÆDIATRY

for May. Dr. A. H. Buckmaster discusses

**Hemorrhage after Abdominal Section: Its Place in Statistics.**

The author is of the opinion that the reason that so little is heard of the deaths after abdominal section lies in the fact that men report only their successful cases and try, as much as possible, to make their results conform to the low rate of mortaliy that those expert in the operation have set. The author says, that since he has had the misfortune to lose a case from hemorrhage after operation, he has had over forty such cases narrated to him by almost as many operators. All of these cases are unpublished.

The author is further of the opinion that the drainage tube as a means of detection of hemorrhage has been overestimated, though in rare instances it may be of service. In support of this he quotes the experiments of Delbert both on dead subjects and dogs, in which it was found that it is almost impossible to keep the peritoneal cavity in communication with the open end of the tube, for if the intestines do not crowd into the end of the tube, it is soon sealed off by the exudate. The author is aware that this is not the general view of the profession, but, nevertheless, it has been borne out by his experience.

In studying the cases which he has been able to collect, the author has noted the following facts:

The greater number arose from the slipping out of the hypertrophied broad ligament from the grasp of the ligature. Next in importance to this cause was the reliance on pressure by means of sponges or gauze. Two cases were due to the slipping of a clamp after hysterectomy. A cause of hemorrhage to which the author claims to have first directed the attention of the profession, is occasioned by the use of the Trendelenberg position. In this position the flow of blood may not be noticed, because, with the hips elevated, the blood pressure in the pelvis is much reduced; but let the pressure be increased, by placing the patient in a horizental position, and the hemorrhage may become free. But of all the cases given none are so fruitful in occasioning disaster as those which presented a broad stump that contained hypertrophied broad ligament.

From his own experience and that of others, the author has come to the following conclusions:

1. When the abdomen is closed after section the case is closed. No treatment short of that which is aggressively bad will influence the after-result. Nothing, therefore, should be left undone with the reservation that the case may require reopening. It is often better to run the risk of death from shock than the risk of death from hemorrhage. Many of the fatal cases were the result of that state of mind which the operator revealed when he said "I was afraid that the patient would die on the table, and therefore quickly terminated the operation by pressure on the bleeding-points by the gauze drain or sponges."

2. When symptoms of concealed hemorrhage are present it is too late to afford the patient more than a forlorn hope.

3. The use of the drainage-tube to indicate hemorrhage is not to be relied upon.

4. It is best, when possible, to enucleate all cases where the hypertrophied broad ligament forms a part of the pedicle.

5. In all cases of suspected hemorrhage the pelvis should not be elevated, for in this position the blood will gravitate out of the pelvis and collect under the diaphragm, where it is impossible to remove it without eventration. This blood will in many cases set up a peritonitis, and it is this peritonitis which it has been blamed for many deaths due primarily to hemorrhage.

6. That a patient may have no bleeding in the pelvis when she is in the Trendelenberg posture, because the arterial pressure is diminished; but when the pelvis is lowered, bleeding of a dangerous character may occur.

Dr. William Wotkins Seymour reports

**Three Successful Cholecystotomies for Gall-Stones,**

with remarks based on six cases. The author feels that excision of the gall-bladder has no field save in gangrene or malignant disease, because its removal does not remove the laboratory in which the stones are formed. He also believes that the performing of the operation in two stages is a retrogression, markedly circumscribing our field of action in the cases with complications which are not to be foreseen and certain to result in incomplete and discrediting operations. The belly can by aseptic pads be thoroughly safeguarded

against bile, and the operation in two stages has no advantages which the simple operation does not possess many times over. The author prefers the incision parallel to the liver border to all others. This oblique incision gives the most perfect access to the gall-bladder and ducts of any incision that the author is acquainted with, at the same time admitting of perfect coaptation with a minimum danger of hernia.

Between cholecystotomy with suture of the viscus to the parietes and cholecystotomy with suture and dropping of the gall-bladder, leaving the peritoneum undrained, he believes the advantage to lie with the former. When the gall-bladder can be sutured well, he can see not only no objection, but an advantage, if the belly is safeguarded by temporary drainage and tamponade. If the stitches hold, the tube can be withdrawn in a few days at least, and convalescence materially shortened. In the cases where it is impossible to bring the gall-bladder into the wound, or where we are obliged, after failing in crushing or needling stones in the common duct, to excise them we can, according to the facility with which it can be done, either suture the opening, safeguarding it with drainage, or we may simply introduce a tube onto the opening and surround the tube with gauze till the belly is shut off. In cases where a fistula persists and proves detrimental to the patient's health, cholecystoenterostomy ought to be done, and the most rapid method seems to be with the Murphy's button. The use of the button, the author thinks, to sidetrack, without removing, stones obstructing the common duct is, in view of the irritative effects of gall-stones, an abuse of an instrument which promises much in its proper field.

The author is of the opinion that the time has come to regard gall-stones as a surgical affection; an affection which requires prompt intervention when the recurrences become at all frequent and severe. Neither Carlsbad water, nor olive oil, nor chloroform and turpentine can dissolve them when once formed, and to expose the patient to the many risks and unutterable tortures of many recurrences is downright wicked. Especially is this so when the mortality of the operations for this disease is extremely small.

Dr. Daniel Longaker, in a paper entitled

**Two Symphysiotomies and an Induced Labor,**

says, that his own personal decision would be not to employ symphysiotomy when the conjugate is below two and three-quarters inches (6.7 centimetres), but to regard the case as one demanding delivery by Cæsarean section under the absolute indication. The author believes that it is preferable to have a vertex presentation after symphysiotomy. Forceps should not be applied until the head has passed through the os, and not until bladder, anterior vaginal wall, and cervix have been retracted. In every case the author has thus far seen these structures accompany the head in its descent to the pelvic floor. In one the forceps were applied early and the head could be seen passing through the os outside vulva. Manually we can supply the support which is lost through the spreading asunder of the divided pubic bones, thus there will be secured less disturbance of the anatomical relations of the post- and infrapubic regions, earlier escape of the head through the os uteri, and less danger of laceration. Failure of fœtal vitality would indicate speedy extraction of the child by forceps even before descent and escape of the head from the os uteri.

Dr. George M. Boyd discusses

**Injuries to the Pelvic Floor and their Immediate Repair.**

The author believes that the forceps is the cause of many tears of the pelvic floor. In his experience we have a new factor in the axis traction rods of the modern instrument as the cause of these injuries. He cautions that the operator should be mindful that while he is making traction in the axis of the pelvic canal he may also be producing, by pressure, serious damage to the pelvic floor. The author also discusses the question as to whether the use of the bichloride douche is objectionable on account of drying the secretions of the vagina, though he comes to no conclusion in the matter. He states that even if it should be proven that the douche did dry or remove the secretions, he would yet favor its use on account as a prophylaxis against gonorrhœal, ophthalmia, and septic infection.

Perineal support has been of no service in his experience, except when extension of the head was favored by pulling the rectum forward. Direct pressure or guidance of the head presenting part in some cases seemed beneficial. In case of laceration of the perineum after labor, the injury should be immediately repaired under anæsthesia, and with this end in view the author has frequently commenced the use of the anæsthetic on the first evidence of injury, with the result that when the third stage of labor was completed the patient was fully under its control, thus avoiding delay. The suturing of the rent should begin from within out, and the first skin suture should be placed much as the crown stitch in the Emmet operation. The author believes that Chinese silk is better for suture material than silkworm gut. After operation the patient should be kept rigidly quiet—catherized every six or eight hours—given bichloride douche, 1 to 8000, daily. In the place of the ordinary vaginal iodoform suppositories, the author prefers the use of a pencil, 4 to 5 centimetres in length, made of iodoform grs. xxv, and sufficient starch and acacia to make the mass, when dry, hard, not easily broken. The advantage of the pencil over the suppository is, that while the suppository will dissolve within one hour and iodoform possibly escapes, the pencil will dissolve more slowly, requiring twelve hours. The pencil is also of advantage when it is desired to carry iodoform into the uterine cavity. The ordinary suppository melting or breaking to pieces in the grasp of fingers or forceps.

The author presents the following conclusions as the result of his experience:

First.—As every obstetrical case is greatly a mathematical problem, so is the safety of the pelvic floor; if the passenger is too large for the passage-way (something must give), a tear, either vaginal or perineal, will follow.

Second.—As it is our duty to study all obstetrical cases before labor by palpation and pelvinity, just as much is it our duty to examine the perineum and vagina after labor.

Third.—That having any injury of the pelvic floor, it should be at once repaired, and a good method to follow is to perform the operation under constant irrigation, using sterilized Chinese silk for sutures, and avoiding infection of the wound by placing the stitches without inserting the finger in the rectum.

Dr. J. A. Freeman contributes a paper on

**Retroversic Uteri.**

The only rational treatment, according to the author, is hysterorrhaphy, or ventral fixation; and he takes the stand that all cases of excessive retroversion should be subjected to this operation, which (according to him) is perfectly successful and safe when done under strict asepsis. The author further says that "Girls should be taught from early childhood to habitually lie upon the side, or, rather, sides alternately, and not in the supine position." The alternate sides should be used in order to produce symmetry of the body.

Dr. John G. Kerr, of Canton, China, concludes his interesting translation of

**The Tat Shang Pin.**

or midwifery made easy. The section on the regulation of the lying-in room is curiously like the same instructions one sees in modern books on the subject. The author states that when the period of confinement has come, two "of those steady, quiet, steady persons" must be selected to be in attendance. "There must not be too many, and it is better that they be relatives. They must with pleasant words request persons not to enter the room. In hot weather it is important not to have too many in the room, for the air becoming vitiated will be bad for the patient, and will cause giddiness, the evil effects of which will not be small. All persons in the room must walk lightly, speak gently, and must not indulge in much talking in order that the patient have quiet repose. It is of the utmost importance to exhort the patient to dismiss all fear, to be quite, to bear the pains, and not to be tossing about. Any remarks about strange and alarming things are especially to be forbidden, also whispering or sighing, for all these things cause her to be in doubt and troubled, and may result in evil.

"Everything in the room must be kept quiet, and in the patient's presence there must be no worshiping of the God, or making vows or invocation of heaven or earth.

"The midwife must enter the room alone, sit down quietly and not make confusion.

"A little food must be given to the patient frequently, such as chicken or duck, or the stomach and lights of hogs; but a little clear broth is better." Then follows certain rules for the determining of true from false labor-pains with reports of cases from the author's practice illustrating his meaning. Another section is "On Nourishing the Womb" while "Diet and Drinks" are discussed further on. Abortion is also considered. In regard to the after-treatment, the patient is instructed to get on the bed and recline on a high pillow, but is not to sleep. Her knees are to be flexed and she must drink a cup of child's urine (though for what purpose we are not informed). The attendants are not to disturb her by loud talking.

The cause of retention of the placenta is said to be because the birth has been forcibly brought on too soon. "During labor the joints are forced apart. In strong persons they close up in a few days, but in weak persons a month is required. Now, if the delivery is forced before the joints naturally open, they will close up again suddenly, so that the after-birth cannot come away." This condition is not considered dangerous. "There is no occasion for fear, and it is unnecessary to take medicine. When the after-birth does not come away, tie a hemp threaded to a fold of the cord and attach a weight to it to keep it from going back. Then cut the cord off short. In from three to five days the placenta will shrink up and come away. The patient must be plainly told not to be alarmed and that she must not listen to the midwife who will want to take it away with the hand, which would be the cause of much damage." Insufficient milk is said to be caused by thinness of the blood and directions for remedying it are given.

[The "Tat Sin Shang Pin" is a popular work on midwifery, in common use among the people of China, and is the standard authority in all difficult cases, so Dr. Kerr states in his translation of the first part of this work which appeared in the Annals of Gynecology for March. Dr. Kerr has endeavored to give a literal translation of the work, the author of which he could not discover, though in all probability the work is several centuries old. Dr. Kerr is to be thanked for giving the profession this curious insight into the teaching of a people that we are accustomed to regard as barbarians. He has already, in a paper read before the College of Physicians of Philadelphia, some years ago, giving an interesting account of operative obstetrics among the Chinese, and we look with interest for whatever he may have further to say on the subject.—Ed.]

The remaining papers in this issue are descriptions of a number of specimens removed by abdominal section, by Dr. William Easterly Ashton, and the discussion of "Fæcal Fistulæ," by Dr. Mordecai Price. In the "Department of Pædiatrics" is a clinical lecture by Dr. J. P. Crozer Griffith.

## MEDICINE.

### Typhoid Fever.

Dr. Jno. Eliot Woodbridge, of Youngstown, Ohio, claimed before the Mahoning County Medical Society that he has been able to abort all cases of typhoid fever coming under his care before the eighth day of the disease. He claimed that typhoid fever can invariably be cured when proper treatment is instituted at a sufficiently early period.

If the treatment (outlined in a very imperfect way by the doctor), merits the attention of the profession, we fear the dogmatic assertions of the writer will find, in time, a level much beneath their asserted value. Prescriptions Nos. 1, 2, and 3 are as below. The trend of the rationale of therapeusis set up in this "shot-gun" is that somewhere here is a specific antiseptic against a predicated typhoid germ:

No. 1.

℞
Podophyllin..... gr. i.
Hydrarg. chlor mitis..... 3i.
Guaiacol..... 3vi.
Thymol..... 3v.
Menthol..... 3i.
Sacch. alb..... 3ii.

M. In very minute doses every half hour to one hour.

No. 2.

℞
Potass acet..... 3i.
Spir. nit. dulc..... 3ss.
Aquæ dist. q. s. ad ..... 3iv.

Sig. One teaspoonful every half hour in water or lemonade.

No. 3.

℞
Eucalyptol..... 3ss.
Spir. rect ..... 3i.
Guaiacol..... 3ii.
Aquæ dist. q. s. ad..... 3iv.

Sig. One-half teaspoonful every three or four hours.

The only drug here with which we are not all familiar is guaiacol, a derivative of creasote. It is an anti-pyretic, even said to be such when applied to the skin. Da Costa very recently speaks of his experience with it:

"He finds that the reduction of fever, which in one case was from 105.4 degrees to 98.6 degrees, is not attended with marked change in the pulse, nor by cerebral disturbances. In the case mentioned, and a few others, a very great reduction was followed by a slight chill, but in one instance, in which the temperature was brought down to 97 degrees, there were present no effects upon the pulse, respiration or nervous system and no chill. The reduction of temperature was most striking in cases of typhoid fever. In pneumonia of a severe inflammatory type, the reduction was comparatively slight, except about the time of the crisis, when a natural reduction would occur.

"As compared with that of the cold bath, the effect of guaiacol is produced more slowly, but is decidedly more lasting. Thus in a case of typhoid fever, the application had to be repeated but 16 times in 7 days.

"The proper dose to be employed will rarely be over thirty minims; excessive reduction of temperature followed the use of forty drops. It is to be painted or rubbed upon the skin which has first been prepared by washing with soap and water. It may be rubbed in slowly with the hand, taking five minutes for the purpose, and the surface then covered with lint or waxed paper. With a temperature of 103 degrees, it would be proper not to use more than twenty minims at the first trial.

"The chief objection to it thus far discovered, is its odor, which DaCosta has found to be best overcome by use of the oil of cloves.

"In private practice, the efficient use of the cold bath is often difficult or impossible, and it may be that here the external use of guaiacol will possess advantages that will give it a wide application."

### Vomiting of Pregnancy.

When a physician has a very stubborn case of the above nature—a case that will not yielded to anything that he has tried—patient of a nervous and excitable temperament—cannot retain even a sip of tea or water—and fast growing into an alarming condition—please try the following promptly, and if the second dose fails to give relief, then I shall write no more; it has never failed in my hands, when ever other known remedy has:

℞
Fld. ext. valerian,..... 3i.
Fowler's sol. arsenic,..... mxvj.
Sodii bicarbonas..... 3i.

M. Sig.—Teaspoonful every two or three hours.

The second dose usually relieves, and your patient will feel grateful indeed. Of course, all are familiar with these drugs, but the above combination is recent with me, and it has done what all known remedies have failed to do in my hands. Small doses of the valerian aggravate the nausea, while large ones quiet the whole system.—Julian Berry, M. D., in *Memphis Medical Monthly.*

### Therapeutics of Phenacetine.

Dr. James T. Whittaker, Professor of Theory and Practice of Medicine, Medical College of Ohio, in his recent popular text-book on medicine, discussing the treatment of influenza, says: "The pain is best relieved by broken doses of Dover's powders, or in the presence of much nausea by phenacetine. Phenacetine may be given in a single dose of ten grains to secure a peaceful sleep." In measles he states that, "Any case of fever above 103° is best controlled by warm baths which may be gradually cooled, or by occasional administration of phenacetine, gr. iii-v, more especially in the relief of the

associated nervous symptoms." In scarlatina he prefers to reduce fever by cold, tepid or warm baths, or ablutions, but if as sometimes happens, it is necessary to resort to the use of antipyretics, he recommends phenacetine as the least injurious." It may be given to a child in a dose of iiss-5 grains, to an adult in double this dose, once or twice in the course of a day. It is of especial value in headache or other nervous distress. It is best administered in capsule or in powder taken directly upon the tongue, stirred—that is, suspended—in milk, or in case of high fever with dry tongue, floated upon the surface of a teaspoon of water." While an adherent of the cold bath treatment in typhoid fever, Dr. Whittaker recognizes the fact that it is sometimes impracticable and impossible. Speaking of the use of chemical agents for reducing fever in this disease, he says that, "the safest of the modern antipyretics is phenacetine, which is best given in a large dose, three grains to a child, five grains in adolescence, ten grains to an adult, at the height of the temperature, which it will reduce in the course of fifteen or twenty minutes, a degree or two with some slight sweating, which in turn aids in sustaining the antipyresis." Dr. A. A. Stevens, in his "Manual of Therapeutics" recently published, sums up his experience with phenacetine as follows: "It may be used to lower temperature in diseases associated with higher fever, such as typhoid fever, scarlet fever, rheumatism and pneumonia. As an analgesic it is an extremely valuable remedy in neuralgia, headache, migraine, influenza, rheumatism and the crises of locomotor ataxia. It has been used with success as an antispasmodic in whooping cough."—*The Medical Fortnightly.*

---

### The Reciprocal Relations of Mitral Stenosis and Pregnancy.

In the April issue of the *Univ. Med. Mag.*, Dr. Herman B. Allyn publishes a very profitable article with the above caption and relates ten very interesting cases of heart disease complicating pegnancy, or pegnancy complicating heart disease. The subject of the paper, he explains, is the reciprocal relations of mitral stenosis and pregnancy—that is to say, on the one hand, the effect of pregnancy upon the heart lesion, and, secondarily, upon the patient in general; and on the other hand, the effect which the heart lesion exerts upon the course of pregnancy and, secondarily, the effect upon the fœtus.

This is brought out admirably by his reports of cases.

Coughs, dyspnœa and pulmonary congestion, with bronchitis are the most common symptoms of mitral stenosis in pregnancy. They appear after the fourth month and increase in intensity as pregnancy advances.

General œdema is not a common symptom. It occurs only in advanced stages of severe cases.

Albuminuria also is rare.

Convulsions or unconsciousness, occurred in six cases.

Cardiac pain, at times amounting to severe angina, occurred in six cases. Palsies apparently embolic in origin occurred in three cases.

His special point in the treatment is bloodletting, preferably by venesection. His indications for it are increase in the engorgement of the lungs or heart, or when constant orthopnœa, cyanosis, edema of the feet and legs, an irregular pulse and weak second pulmonary heart sound developes.

There is no doubt as to the great value of blood-letting in suitable cases. It relieves the engorged right heart, and by lessening the volume of blood upon which it must contract, permits of compensatory hypertrophy. The value of loss of blood is shown practically by the statistics already quoted—hemorrhage in some form occurring in 18 of the 37 favorable cases and in only eight of the fatal cases.

The puerperium should be closely watched and the patient prevented from rising or doing anything to cause overdistension of the dilated and weakened right auricle and ventricle.—*Ft. Wayne Med. Mag.*

---

### Habitual Headache as a Prominent Symptom of Some Nasal Diseases.

Dr. Scheinmann makes the statement that most nasal diseases are accompanied by more or less headache, in many instances the headache becoming habitual. In both neurasthenic and hysterical persons, local examination of the nose should not be forgotten, as oftentimes the seat of the trouble is entirely within the nares. Headache is sometimes the only symptom of a diseased nose or accessory cavity, and by cure of the nasal disease the headache vanishes. In neurasthenic persons cocainization of the diseased parts will oftentimes cause a disappearance of the headache. One of the most frequent causes of headache (from nasal disorder) is hypertrophic swelling of the turbinateds, though the observations of the author prove that empyema of the antrum of Highmore, even combined with phlegmon of the orbit may be only indicated by headache. Cure of the empyama removes the headache. The author has found that carious gummatous processes, crests and spines of the nasal septum, and oftentimes lesions that seem quite unimportant, may be the cause of violent headaches, as proven by cases coming to his notice. He concludes by saying that in all cases of headache it is important that the nose should be thoroughly examined.—*Berliner Klin. Woch.*

---

### Mucous Disease.

This is a very frequent disease of children, and is most common between 3 or 4 and 10 years of age. It consists of an increased secretion of mucous from the internal surface of the alimentary tract, which interfers mechanically with digestion and absorption of food, and by its influence in impeding nutrition, often excites suspicion of the existence of tubercle.

The symptoms are slight at first, and become more severe as the disease advances in

its course. The child is dull; disinclined to exercise, and complains of weariness. He becomes pale; loses flesh; his spirits are low; takes no pleasure in amusements, and is listless; sometimes crying without cause. He is drowsy during the day, and restless at night; his sleep often being disturbed by frightful dreams. Sometimes he arises from bed while asleep, and walks from room to room. Nocturnal incontinence of urine is frequently complained of. The appetite is capricious, and each meal is followed by flatulence and uneasiness. The appetite may remain good; sometimes the hunger cannot be satisfied.

The tongue is flabby and indented by the teeth, and has a glossy, shiny look, as if it had been brushed with mucilage.

The bowels are either constipated, or move frequently and scantily, and the stools contain large quantities of mucus.

The complexion is often jaundiced. The skin becomes rough and harsh.

The glands of the neck are liable to become enlarged on irritation.

The temperature of the body is seldom elevated above normal.

Worms form a frequent complication of this derangement.

*Treatment:*—Pay strict attention to the diet. Farinaceous foods must be forbidden, and the child nourished on meat, eggs and milk. Regulate the amount of food taken at each meal, and have them often.

At night bathe patient with hot water, and after drying rub in oil.—*Extract.*

---

### Ice in Phlegmasia Alba Dolens.

Dr. John A. Miller (*Pacific Med. Journal*), in treating on the subject of "milk leg," speaks highly of the efficacy of the cold treatment of the disease. He first used it in 1886, and since then has used it in six cases with uniform and decided success. The procedure was in the following manner. An ordinary large towel was dipped into iced water, wrung out and clapped around the affected limb; a heavy flannel roller bandage was then applied from the toes upward to the groin. On the most painful parts, like the inner aspect of the thigh, the popliteal region and the calf of the leg, were laid rubber bags filled with ice. These were kept in place by a circular binder, independent and outside of the roller bandage. The patient was a little shocked when the cold towel was first applied, but the unpleasantness was only momentary, and then the reaction brought ease and comfort. She desired the ice bags to be renewed quite often at first, as she claimed they relieved the pain, as anything else had never done before. The pain was entirely controlled by the cold. The temperature dropped from 103° to 100° the next day, and the patient commenced to improve, which continued uninterruptedly. The towel was freshly dipped from four to six times in the twenty-four hours. As soon as the patient experienced relief, she was quite anxious to endure the temporary chill from a fresh compress, because the limb felt always better for it afterward. The towels soon became dry and hot, and this gave rise to painful symptoms again.—*St. Louis Medical and Surgical Journal.*

---

### Period of Infection.

The period of infectiousness of contagious diseases, according to the State Health Board of Pennsylvania is:

Small-pox.—Six weeks from the commencement of disease, if every scab has fallen off.

Chicken-pox.—Three weeks from the commencement of the disease, if every scab has fallen off.

Scarlet-fever.—Six weeks from the commencement of the disease, if the pealing has ceased and there is no sore nose.

Diphtheria.—Six weeks from the commencement of the disease, if sore throat and other signs of the disease have disappeared.

Measles.—Three weeks from the commencement of the disease, if all rash and cough has ceased.

Mumps.—Three weeks from the commencement of the disease, if all swelling has subsided.

Typhus.—Four weeks from the commencement of the disease, if strength is re-established.

Typhoid.—Six weeks from the commencement of the disease, if strength is re-established.

Whooping-cough.—Six weeks from the commencement of the disease, if all cough has ceased.

Under judicious treatment the period of infectiousness may be considerably shortened, but no child suffering as above should be admitted to any school after a shorter absence, and then should be provided with a medical certificate that he or she is not liable to communicate the disease.

Length of Quarantine.—Teachers or children who have been exposed to infection from any of the following diseases may safely be re-admitted to the school, if they remain in good health (and have taken proper means for disinfection) after the following periods of quarantine:

Diphtheria, 12 days; scarlet fever, 14 days; small-pox, 18 days; measles, 18 days; chicken-pox, 18 days; mumps, 24 days; whooping-cough, 21 days.

Adults may be re-admitted immediotely, if they disinfect their clothes and persons.

---

### Olive Oil and Chloroform for Gall-stones.

It is now generally understood that olive oil taken in large quantities is a useful remedy for facilitating the passage of gall-stones through the common duct into the intestine. Numerous cases have been reported in which this remedy has succeeded. In some cases, doubtless, the round, greenish colored masses which may be found in the stools of a patient who has taken considerable quantities of olive oil, may be mistaken for gallstones by one who is inexperienced in detecting these calculi; but a sufficient number of well-authenticated cases in which actual calculi have been observed, have been recorded to

give the remedy a standing sufficient to make it worthy of trial. The efficiency of the remedy may be greatly increased by simultaneously administering chloroform in medicinal doses. Opium is to be avoided in these cases, for while it relieves the pain, it at the same time increases constriction of the duct, whereas chloroform both relieves the pain and relaxes the involuntary muscular fibers of the duct, thus facilitating the passage of the calculi.—*Modern Medicine.*

### Antiseptic Mouth-Wash.

In his "Treatise on Disease of the Mouth" E. Maurel gives the following formula:—

℞ Alcohol of 850 degrees.....3ij.
Tincture of eucalyptus.....3v.
Tincture of cinnamon.....3iiss.
Tincture of rosemary.....3i¼.

M. Sig.: A teaspoonful to a glass of warm water.

### Treatment on Enteric Fever.

Maillart (*Rev. de. Med.*, November, 1873.) begins a study of cases of enteric fever treated by the internal administration of large quantities of water. The first object of treatment is to destroy the micro-organism, but failing this the action of their products must be neutralized. These toxalbumins are excreted by the kidneys. In enteric fever the urine is diminished in quantity, and the skin does not act, hence the object should be to encourage these emunctories. In order that a large quantity of water should be excreted, a large quantity must be provided. Subcutaneous infusion may be adopted if the patient is unconcious, or in severe hemorrhage. Water can also be supplied by rectal injections, but the simplest way is to make the patient drink copiously. The author endeavors to ascertain the effect of this treatment on the different symptoms in fourteen cases of enteric fever minutely studied. Only one case died. The patients take to this treatment readily. Exceptionally as much as 16 litres were taken in the day. The mouth became moist, and the trouble in swallowing owing to dryness of the pharynx disappeared. Thus antisepsis of the mouth is more easily effected. The stomach tolerates this treatment; in exceptional cases vomiting occurred at first, but this soon ceased. The water was excreted by the kidneys and skin, the quantity of urine being greatly increased.—*M. A. Practitioner.*

## HYGIENE.

### Water Purification by the Alum Method.

It has long been known that addition of small quantities of alum to impure water has the effect to cause the precipitation of its impurities, and this method has been used, sometimes on a large scale, as a means of purifying water. Max Teich, of the Institute of Hygiene of Vienna, has recently made a study of the value of this method, and finds that while the method offers no objection from a sanitary standpoint, and is capable of killing cholera germs, typhoid fever germs are not materially affected by it, and treatment of the water for at least twenty-four hours is necessary to destroy the germs of cholera.—*Modern Medicine.*

## OBSTETRICS.

### The Conduct of Ordinary Labor Through External Examination Solely.

Leopold and Sporlin (*Archiv f. Gynakologie; Med. News*) make a warm plea for limiting examinations made in the course of ordinary labor to the external parts, and the advantages of such a course. Infection is thereby avoided; the natural sense of modesty of the parturient is not offended; and careless rupture of the membranes is avoided. Skill in external examination is acquired with reasonable readiness. In the large majority of cases such examination alone is sufficient for the recognition of the position and presentation of the fetus, and for the study of the course of an ordinary labor. As there can be no objection to its frequent exercise, abnormalities of paturition may the more readily be detected early, and means of correction promptly employed. Experience soon teaches the difference in the position of the fetus assumed in case of pelvic contraction on the part of the mother. The position and presentation having been recognized by external examination for the determination of possible pathologic conditions of the birth-canal need be but brief, and can be conducted with great care. For the attainment of this desirable result it is essential that the obstetric pupil familiarize himself thoroughly with the conditions of normal labor as determined by physical external examination, as well as with the physiology of normal labor. Obstetric operations are principally to be taught upon the phantom.

THE
MEDICAL AND SURGICAL
REPORTER.

No. 1946. PHILADELPHIA, JUNE 16, 1894. Vol. LXX—No. 24.

# ORIGINAL ARTICLES.

## CONTRIBUTIONS TO OBSTETRICS AND DISEASES OF WOMEN.*

[NUMBER ONE.]

THEOPHILUS PARVIN, M. D., Philadelphia.

Preliminary Remarks.—In presenting the readers of The Medical and Surgical Reporter with the first of a series of papers under the above title, a few prefatory observations are made, more especially concerning the purpose and the plan of these contributions.

One of the acutest observers and most vigorous reasoners of the century, the late Archbishop Whateley, once remarked: "Some people speak because they have something to say, and others because they want to say something." The writer trusts he has something to say—something that may possibly prove useful to some readers—he would be silent rather than speak from the desire to say something.

The papers will be chiefly clinical, and thus the report of a case or of cases will be presented, and this followed by reflections, imitating the method employed by that able French obstetrician, La Motte, whose great work, published nearly two hundred years ago, has hardly been equalled as a contribution to clinical obstetrics. Occasionally a subject belonging to obstetrics or diseases of women will be discussed, without any clinical observations.

I shall not refrain from narrating some of my own errors when there is hope such narration may haply enable others to avoid similar transgression. Lord Bacon wisely said, "men mark when they hit, but never when they miss." And is not this often true in medicine, especially in its surgical department? We frequently read of brilliant operations, only rarely, if at all, of black failures by the same operators. So, too, there is a tendency to proclaim the errors of others, and to conceal our own, in this respect possibly even proving that the statement made by the Marquise of Queensberry, the famous "Kitty" of Prior, in a letter to Dean Swift, is not exclusively true of women: "Most women have an inconceivable pleasure to find out any faults, except their own." None of us is so wise in diagnosis, and so skillful in treatment that he never makes a blunder; infallibility belongs no more to doctors than to other human beings, and they who seem to claim it, harshly judging their fellow practitioners, constantly and publicly proclaiming their own greatness and success, may be temporarily enthroned as golden gods, but will by-and-by prove upon close examination only gilded clay

* [This series of short papers is contributed by special request of The Reporter. The preliminary remarks indicate the scope of the series. The name of the writer is sufficient guarantee for the value of the observations recorded.—Ed.]

or polished brass; their example is evil, and their work is of no permanent good to society or to the profession.

A few words more: The pompous, and, so far as etymology is concerned, the perverted word gynecology will be ignored in these papers, and so, too, its derivatives. Our literature is becoming loaded with needless neologisms, and many a doctor frankly confesses that he fails to understand some writers, unless while reading their articles he has at his elbow the most recent medical dictionary.

So, too, Zolaism will be given no place. The reaction in general literature against the naturalism of Zola has begun, and so, too, similar reaction will come in medical literature. Illustrations are given in text-books, in medical journals, and advertisements addressed the profession, both at home and abroad, needless nudities of the female form and sexual organs, and descriptions and discussions* in regard of subjects which neither exalt nor instruct, do not help in the diagnosis nor in the cure of disease, and invite pruriency rather than purity of thought, aversion more than approval. No one could imagine that Sir James Y. Simpson or Hugh L. Hodge would utter what is now spoken by some of their successors, or permit in their volumes such illustrations as we now sometimes see in works on diseases of women. Those of us who thus transgress will find no pleasure in the retrospect of our transgressions, conscious that we have thereby not increased but lessened "the sweetness and light" of professional life.

After forty-two years spent in practice, nearly three-fourths of those years engaged also in medical teaching, it is quite possible I will at times express opinions differing from those that are prevalent to-day; but a doctor ought to cultivate catholicity of creed, hoping thus possibly at least, to reconcile occasionally discordant views, taking from each such element of truth, great or small it contains, abhorring that dogmatism which too often is manifested in professional beliefs and practice. Positiveness of assertion and obstinacy of belief may arise from imperfect knowledge, and looking at a question in one part, or from the limits, the small window of personal experience, ignoring what others see from their windows. Occasionally one is tempted by the medical dogmatist to repeat to himself the question of Montaigne, "is there anything so assured, resolute, disdainful, contemplative, serious, and grave as the ass?"

But I conclude these introductory observations, which may seem to some too discursive, but which have not been without design, that possibly other readers may see and appreciate.

---

### ATRESIA OF THE UTERUS IN LABOR.

The patient was seen in consultation with Dr. P. H. Markley, of Hatboro, Penna., and I first present the Doctor's history of the case before my visit: "Was called to see Mrs. L., primigravida, January 19, 1894, in the evening. She was apparently in the first stage of labor, nothing unusual having occurred during her pregnancy. Making a vaginal examination, much to my surprise I could find no os uteri, nor the slightest indication of where it should be. Thinking that possibly the pains might be false, I directed a rectal injection, and used hypodermically one-fourth of a grain of morphia. The pains were not set aside, but rather intensified. I repeated my vaginal examination, the labor having been in progress some hours, but after the most careful search could find no trace of an os. I felt satisfied that there was complete occlusion of the uterus, and sent for Professor Parvin."

It was impossible for me to immediately answer the call, and the second night had come before I reached the patient's residence, some fifteen miles from the city. I found a strong, healthy woman in active labor, the severity of her suffering being mitigated by the inhalation of ether. While she was brought more completely under the influence of the anæsthetic, I made a careful vaginal examination. The head was in the pelvis, making a large hemisphere, to which the uterine wall was closely applied, but nowhere could the os be discovered; this examination was made first, the patient lying upon her back, then upon her right, finally upon her left side; the entire hand was introduced into the vagina, the right hand when she was upon her left side, and the left when she was on

* Whenever such references are pertinent they are proper; but when impertinent they are impudent. The reader will here observe I am using the adjectives in their etymologic sense.

her right side; every square inch of the hemisphere was deliberately and carefully explored, but I could learn nothing more than my friend had done. If it had been daylight, and if a suitable speculum had been at hand, of course it would have been our duty to ascertain if the eye could tell us what the fingers failed to do; but a poor artificial light, and no speculum of any sort rendered impossible such exploration. Again examining with the finger, I thought I discovered a very slight and small elevation, comparing a little thing with great, a sort of cliff overhanging and hiding the entrance to a cave; the position corresponded with that which the os would normally occupy. This conclusion having been reached, I first endeavored by gentle pressure with a silver female catheter, then with a director, finally, with a probe to make an opening into the uterus—of course, severe or strong pressure while effecting a perforation of the uterus, would have almost inevitably done more or less serious injury to the child's head; the instruments available were by no means many, or best—I had known nothing of the nature of the difficulty before my arrival. There was now but one thing to do when penetrating with a blunt instrument seemed impossible, or dangerous, and that was to cut the obstructing tissue; accordingly a small pair of scissors held in one hand, the points guided by two fingers of the other hand to the slight elevation found upon the uterine surface which has been mentioned, and then the tissues were carefully snipped through, the incision permitting the introduction of a silver catheter. The catheter was used to stretch the opening, then a finger was introduced, and soon two or three were employed to dilate the os. In the course of half an hour the os was completely dilated, or dilatable. Wallace's forceps was applied by Dr. Markley, and a large, living, uninjured child was delivered, considerable force being required for the extraction. A hot water antiseptic injection of the uterus was made after the delivery of the placenta; nevertheless there was considerable hemorrhage, so that compression of the uterus and the administration of ergot were necessary. In a few hours reaction was satisfactory, and I returned home. Forty-eight hours subsequently I was sent for on account of a chill followed by a temperature of 103.° I found the lochial discharge offensive, and washed out the uterus very freely with creolin mixture in hot water. The fever soon declined and disappeared. Subsequently the patient's convalescence was neither interrupted nor delayed, except by a slight attack of *phlegmasia alba dolens*. Dr. Markley has recently informed me that both patient and child are quite well; the uterus has somewhat greater than normal length, and the cervix was apparently torn.

REFLECTIONS.—Complete, spontaneous atresia of the os uteri observed in labor is very rare, so rare that some obstetricians deny its occurrence, while most admit atresia may result from cauterization. Delore* refers to the observations of Dubois and Depaul as proving beyond doubt that spontaneous obliteration of the cervix may occur. He also narrates the following case observed by him: The patient was forty-two years old, a primipara, and had not had any anterior lesion. She was exhausted by several hours in vain efforts. At the fundus of the vagina with speculum and finger it was impossible to find the least trace of the orifice, or of projection of the neck. A crucial incision was made, and the labor progressing slowly, the forceps were used. Martin,† on the other hand denies atresia, and explains the alleged instances as simply those of stenosis, this being so great in some cases that only a sound as fine as a hair can penetrate the opening, and yet permitting the escape of fluid from the uterine cavity. In considering the diagnosis Martin, after referring to the exposure of the vaginal vault with the speculum, and seeing upon a round mass, pressed downward, a smooth shining, stretched, bluish-red surface, where one observes upon one side, when not in the median line, a pin-head opening, or the radiating white glistening cicatrix, adds that the membranes, as a rule, rupture from the energetic contractions of the uterus, the amnial liquid escaping and there can be seen, especially during a uterine contraction, a fine stream pass from the opening. The last point, which I do not remember to have found in any other work upon obstetrics, seems to me of considerable importance in distinguishing between atresia and stenosis; of course, too, when one sees this stream, he not only makes a certain diagnosis, but also at once

* Traite Pratique de l'Art des Accouchements.
†Lehrbuch der Geburtshilfe von Dr. A. Martin, 1891.

knows where the orifice is. My friend, Dr. Markley, in talking with me over the case, asked me when the membranes ruptured, and I could not answer his question. Therefore, in reflecting upon the matter, I do not think it impossible, in view of Dr. Martin's statement, that the os might not have been impervious, though by all the means that were available to Dr. Markley and myself, it was impossible to come to any other conclusion than that there was complete atresia, and that the amnial liquor had made slow and silent escape. Nevertheless, it would be advisable in a similar case to carefully examine by sight for fluid coming from the uterus, when such examination can be made before making a positive diagnosis.

In the tenth edition of Schroeders' *Geburtshulfe* edited by Olshausen and Veit, 1888, reference is made to the closure of the mouth of the uterus occurring in pregnancy, this atresia sometimes being the consequence of cauterization. In the most recent German work upon obstetrics, that of Kaltenbach, 1893, stenosis, but not atresia, originating in pregnancy, is described. This author, as others have done, refers to the imminent and unavoidable rupture of the thinned cervical wall rather than the yielding of the stenosed os, if suitable obstetric help fails.

The directions for the treatment of this atresia given by Winckel, (*Lehrbuch der Gérburtshülfe*, second edition, 1893) in case perforation cannot be effected with finger or sound, are to expose the part in the vicinity of the mouth of the womb with a duckbill speculum, after first disinfecting with four per cent. carbolic acid solution, when the tissue is held by tenacula, and either with or without previously pencilling with a four per cent. solution of cocaine, a superficial crucial incision is made through the membrane, and followed by, perhaps, excision of the four ends of the flaps these produced. He employs a vaginal injection immediately afterward, of a three per cent. carbolic acid solution.

But without further consideration of the disputed question as to atresia of the os originating during pregnancy, the obstetrician in making a diagnosis should bear in mind the possibility of sacciform dilatation of the posterior wall of the uterus, and mistaking it for atresia, as in the case reported by Depaul.* This error is impossible if the anterior vaginal vault is accessible, and is carefully explored.

## CONTAGIOUSNESS OF TUBERCULOSIS.†

J. C. SPRAE, M.D., Norristown, Pa.

Whether or not tuberculosis is contagious is not a new question, though 'til very lately it has not attracted much attention. About one hundred years ago, in Naples, compulsory registration of those ill of phthisis, and the destruction of the bedding, furniture, etc., after death, was rigorously enforced by law, and this was the practice until forty years ago. I have myself known Americans in Italy and the south of France, put to much expense and trouble by claims arising out of this idea which still lingered in the minds of the ignorant, though the law was repealed as early as 1855.

The evidence is positive that this way of dealing with phthisis in Naples neither lessened the number of cases, nor in any way benefited the city.

About the year 1870, Dr. L. F. Flick began his painstaking investigations in the Fifth ward of Philadelphia, and soon announced his belief that tuberculosis was contagious, and that the house of the sufferer was the special centre of infection. But his reports being at variance with the observations of medical men in general, were not seriously considered.

With the discovery of the tubercle bacillus, in 1880, bacteriologists and pathologists were able to demonstrate the infectious nature of this disease by the inoculation of animals, and in the course of the past year a number of American societies, among them the Philadelphia County Medical Society, passed resolutions declaring the disease contagious, and recom-

† Read before the Montgomery County Medical Society, May 9, 1894.

mending all cases to be registered by Boards of Health.

Dr. J. S. Billings, the collator of the medical statistics of the census for 1890, estimates there are about six thousand cases of consumption in Philadelphia, and on the basis of relative population Montgomery county would have eight hundred cases and Norristown one hundred and thirty. By the same method of reckoning there are in the United States about half a million cases of consumption. I take it these figures do not include surgical tuberculosis.

Anything affecting the liberty or personality of this large number of citizens is naturally a matter of importance. The strongest, and indeed the only considerable evidence presented by the contagionists, is the fact that the disease is reproduced in animals by inoculating them with the tubercle bacillus. It is found that the reproduction of the disease by inoculation, even in the most susceptible animal, the guinea-pig, is by no means certain and easy; and that the growth of this bacillus, even in specially prepared culture media, is more or less difficult; that slight variations of temperature, dryness of the atmosphere, and the presence of other organisms, each or any of them kills the tubercle bacillus. I go into these bacteriological details to show how unfair is the inference that when there is proof of contagion by inoculation, it necessarily follows there will be contagion from person to person in the ordinary course of daily life. We know of several diseases that are most certainly reproduced by inoculation that as a matter of fact never, or but very rarely spread in the ordinary intercourse of mankind. Syphilis may be cited as one of these.

To my mind the strongest evidence of the noncontagion (I mean in the ordinary sense of that word) of phthisis is the fact that practicing physicians attending thousands of cases for months and years have failed to note this feature in their consumptive cases. They certainly are better witnesses in this matter than the bacteriologist who perhaps has never followed a single case of this disease through its course in the family. It is true that now and then there is a second case in the same house, probably after a long interval, and this is easily accounted for by the general prevalence of the disease. It is claimed that since attention has been directed to the destruction of the sputum, phthisis has measurably diminished in some of the great cities of the world; but this, I take it, is amply accounted for by better sanitation in these centers of population, as practiced in the last ten years especially.

The medical history of all the resident physicians in the Pennsylvania Hospital for seventy years furnishes most conclusive proof. There are 147 of these gentlemen, only one of whom died of consumption, and he not for five years after leaving the Hospital; and, further, he was in poor health before he became a resident. Remember, too, sixty years of this time was a period when no attention whatever was paid to the destruction of the sputum of the many cases of phthisis constantly found in the wards; and also when no one thought for a moment that consumption could be in any degree contagious. And besides, all these young physicians were passing through the most susceptible period of their lives with respect to this disease. This history is certainly most interesting and important. Contrast the statistics supplied by these one hundred and forty-seven young men with that of a similar number of students in any one of our colleges where they are not specially brought in contact with this disease, and the record of immunity could not possibly be better. And where the same number are employed in unsanitary work-shops, I am sure many would certainly become consumptive.

Contagious diseases have a well-marked period of incubation, but phthisis has not, except in the case of animals infected by inoculation. A herd of previously healthy cattle becomes infected with tuberculosis. There has been no inhalation of dried sputum in all probability; the herd indeed has been confined within known limits, such complete isolation as would be for mankind the strictest quarantine, and yet tuberculosis has effected an entrance. A recent writer cites the peculiar anatomical safeguards, or sentinels, of the breathing apparatus of man, by which he is able to exclude, in so many instances, the tubercle bacillus, and thus endeavors to account, in part, how it is so many persons escape. He forgets that the same breathing apparatus is quite powerless to stay the entrance

of really contagious germs, as in small-pox, where one whiff is followed most certainly by the disease in fourteen days. It is, doubtless, the absence of conditions favorable to the growth in the lung of the tubercle bacillus that insures our safety. If consumption were really so contagious as some would have us believe, the hotels at Lakewood, Fortress Monroe and St. Augustine would be pest houses, and Cairo, Algiers and Nice would be plague spots, and the latter city most of all, because it was a famous winter health resort for the Romans as early as the days of the Empire.

Many of us will recall how some ten years ago a few sanitary enthusiasts advocated compulsory cremation as a sanitary necessity, and declared war on all cemeteries. Indeed, I well remember how this proposition very near came to passing the American Medical Association, in 1886, at St. Louis. About the same time we had the syphilis fright, and public drinking cups, barber-shops, door knobs and the like were all declared highly dangerous.

Registration of tuberculosis as a contagious disease means for the registered ones and their families surveillance, publicity and oftentimes the painful necessity of violating confidences by the attending physician. It further means inhibition as to attendance at school and church and other untold hardships to the sick. It would give the consumptive the feeling that he was officially declared a disease-spreading person, and the consequent worriment, with all hope cut off, would surely defeat the best efforts of the physician at amelioration or cure. The sick would first be shunned and then neglected. Practicing physicians of experience know of their own personal knowledge that the facts do not warrant the State in imposing these hardships on this class already overweighted by misfortune. We can do much good, I am sure, by assuring these sufferers of our sympathy and protection, and by holding out to them, or at least some of them, the undoubted promise of restored health by reason of modern therapeutics and curative climate.

## CELLULAR RADIATION.

G. P. HACHENBERG, M. D., Austin, Texas.

An accident met with recently has induced me to communicate this paper.

In stepping out of a phaeton I struck my left hand against the edge of an iron rod. I had on at the time a pair of heavy kid gloves. The blow made no rent in the glove, but caused an abrasion of the skin on the outside of the hand, about three-quarters of an inch in diameter. For a few hours the wound pained me very much, causing considerable constitutional disturbance. The next morning I was sick with *la Grippe*, but my wound was painless. In the afternoon I noticed a radiation of delicate straight lines surrounding it, extending from one to two inches from the wound, about one-eighth of an inch apart, slightly bulbous at their connection with the wound, and at the periphery of the radiation, so fine that they hardly could be seen. The color of these lines was the same as the skin of the hand, with no appearance of inflammation. The lines were only seen when the hand was in a state of flexion.

I gave the wound no special treatment, but left a layer of blood on it to dry, to exclude it from exposure to the air. The radiation daily diminished in size from the circumference, and had almost disappeared, in about ten days, or rather within the "age of resolution," leaving a greatly diminished size of the wound in form of a scab. When the scab was removed, the cicatrix followed by a dry process, leaving a slight trace of the radiation, and its connecting vascularity.

What is the nature of this radiation, and what is its function? The lines were geometrically straight, and could not be vascular in nature; but evidently were of a intercellular material, developed under fixed laws of its own. The radiation was caused by a traumatic irritant. Although its lines were seen but on the surface, there is no doubt they existed and radiated in the same manner from the wound into the surrounding deep tissues. In the case of a wound deeply imbedded within the body, as a gun shot wound, such a

lineal cellular organization would surround it from all points.

The formative process of these lines is primarily effected by the wound itself. The traumatic irritation caused a contractility of the connective cellular tissue, aiding the migration of the intercellular cells to the raw surface of the wound, where their energy became augmented by a vital affinity with the fibrine exudation from the local congestion. This affinity now established transmitted its vital influence in a direct line to the rear cells, forming the lines in question. The immediate cells thus forced by its own innate power, to the wound pass through a transformation, as it surrenders its blastema to the inflammatory exudation in the formation of granulation. When the granulation, or rather the metamorphasis into exudative cells is about completed, the radiation diminishes, and it is the peripheral portion of the lines that first disappear.

But what becomes of the last issue of these lineal cells, after the wound is healed, and they are no longer in demand? It appears when cells forming these lines are no longer needed, they having not the power to recede into their native locality, are changed into connective cells, they lose their shape, size, color, elasticity and power of propagation. It appears here lies the secret, why when any part of the body has been seriously damaged by a wound or by a disease, it has not the same recuperative power it had before; and it even accounts for the predisposition of the same disease that existed once before. As the ultimate locus of life is in the cells (which we know by the primordial cell, and its power of propagation), it is when these are impaired we find the cause of decay in old age, and the remote cause of disease by fault of assimilation and nutrition.

The physiology of cellular radiation, in connection with wounds, has some very interesting features. Its reciprocal action with the wound itself regulates and builds up the healing process. If the traumatic inflammation is, so to speak, within physiological bounds, we have what we call union by first intention. But when the balance of this reciprocity does not exist, we have ulceration, fungus growth, or even gangrene. The contractility of the connective cellular tissue and the mobility of the intercellular cells gives a prompt response to the irritation of the wound. It appears to be an independent reflex action from the wound itself, and is not connected with any muscular structure, and is even without nerves.

Cellular radiation only assumes a pathological feature when subserving to some existing disease. I have my doubts if it is ever etiological in its primary action. It is on this very point we find Virchow and Rokitansky's cellular pathology not tenable. Cells not connected with vascularity have no pathology. The former made a significant remark in regard to the individuality of intercellular cells, from which we draw the inference, that they are not etiological of disease, but may be readily destroyed by a high inflammatory action. He says: "Every individual cell may run its own peculiar course, may undergo its own peculiar changes, without the fate of the cell lying next it being necessarily linked with its own." The intercellular cells have a system of their own; in many of their functions they are independent of the connective tissues, and the nervous and vascular systems. They have an intimate relation with the capilliary circulation, not by a direct communication, yet still in a way to become the recipient of blastema by endosmosis. It is true that a parent cell may have its anomalous development, but that would not come within the range of our consideration.

Nearly all topical medical treatment has its effect on cellular radiation. For ages local remedies were administered with the view to control nervous and vascular action, when often, in a direct manner, they had but little to do with either.

I will briefly refer to a few cases in my own practice to verify this statement:

1. In amputating a finger, I dipped the stump into the spirits of turpentine before applying the dressing. A healing of the first intention followed. Modern surgery would ascribe this ready healing to the antiseptic properties of the remedy. This, however, was not the case; for it was the application of turpentine that aroused the energies of the cells, in a way to favor the formative process.

2. In the summer of 1866, I operated on a maiden lady of great obesity, to relieve her of strangulated inguinal hernia. The operation gave her immediate relief; but the depth of the wound, the hot

weather, and the plethoric condition of the patient gave me considerable uneasiness as to the prognosis of the case. I closed up both the ring and the external opening with sutures, and as a prophylactic to pyemia and gangrene, kept a compress over the wound saturated with a weak solution of Labarrque's solution. The wound healed rapidly with very little suppuration. Then I could not fully account for the speedy recovery of my patient. It is true I gave credit to the antiseptic treatment and the recuperative powers of nature, but there was an auxiliary that favored the recovery I could not account for, for I remember not a drop of the solution, for obvious reasons, was allowed to enter the wound itself. In my retrospection of the case now, I see how Labarrque's solution stimulated cellular radiation, and no doubt favored the rapid recovery of my patient.

3. In the late war having in charge a hospital, one evening a soldier was brought in with double pneumonia. He labored under great dyspnœa, cyanosis, and other unfavorable symptoms. He was put to bed, and I ordered a large compress saturated with spirit of turpentine to be applied to his entire chest, to be left on all night, if the turpentine were tolerated. Next morning the patient was greatly relieved, and with a general treatment that followed he finally recovered. Then I gave all credit to counter-irritation for the happy effects of the case, yet, from my present views of the case, I believe if I had blistered the man, in all probability he would have died that night. I will not stop here to give the differential therapeutic effects of the two irritants. But what did that counter-irritation effect? Was it only forcing a vascular circulation to the surface? Not at all. It transposed the pulmonic irritation to the surface, followed by arousing a full energy of the cellular radiation of the entire chest. As soon as this was effected the *recently* formed pulmonic hyperæmia was readily overcome. But had the pneumonia been in a more advanced stage, the treatment would not have saved the patient.

When an inflammation sets in, under the storm of a violent vascular action, followed with rapid infiltration, the cellular radiation immediately follows to resist (rather to repair) the morbid action; but where the inflammatory action is so much greater than the cellular resistance the latter rather increases than diminishes the inflammatory force; therefore, it may appear to become a pathological element in the disease. This question throws some light on the subject of the administration of antipyretics with good effects.

Cellular radiation as a physiological factor in the animal economy resists all diseases; but when it fails to overcome a morbid resistance it may be the means of doing great harm. It is thus in syphilis, cancer and infectious miasm it disseminates the seed of the disease throughout the body. This explains why irritating topical applications to cancerous growth, may cause cachexia, and shorten the life of the patient. Therefore to take advantage of this cellular force, we have to take into consideration what resistance it may meet, as in inflammation, tumefaction, granulation, ulceration, fungus or malignant growths, etc. When no great resistance is in the way, as in recent wounds and inflammations, its recuperative effects are readily manifested, but where they do exist they must be removed if possible to gain any advantage. For example: in recent ophthalmia a mild sedative alterative collyrium may give relief in a day or two; that is the collyrium holds the irritation and congestion at bay, whilst the cellular radiation is effecting a cure by resolution; but let the ophthalmia be of a chronic nature with obstinate painful granulations, although the cellular force is not withheld, but rather augmented, no cure is effected, but in the strugle with the inflammation, causes tumefaction of the lids, and adds to the granulation itself. Now what is indicated is the heroic treatment to break up the granulations with the knife or caustic, to make way for a resolution on the system mentioned.

The modus operandi of cellular radiation on open wounds and parenchymatous inflammation are not the same. The former is an exudative process, and the latter ends in a force of absorption. In our case of double pneumonia, the *limited continuous* irritant to the chest finally overcame the pulmonic irritation, which was the initiatory stage of inflammation, and at the time bringing a surplus of cellular force to the surface; the two adventitious forces in the lungs were now properly balanced, and resolution at once ensued.

It is not the case, as is generally supposed, that an external irritant alone will compensate for an internal congestion. Congestion before it causes organic changes, if overcome by proper means, disperses with wonderful rapidity.

The contractility of the connective cells toward the seat of the wound, has forcibly revealed itself in the following case:

4. In 1860 a teamster in a state of intoxication fell from his wagon, that was heavily loaded with brick. One of the wheels passed over his head, tearing away the integuments from the left side of the head, leaving a flap lying over the left upper side of the face. It appeared as if a large portion of the pericranium was shaved away with the flesh. I carefully cleansed the wound, and brought the flap to its place as well as I could, mainly with sutures. An inflammatory action set in, and tore out every suture I had made. I replaced them repeatedly, but noticed that the resistance of the flap became less every day as the inflammation lessened, and finally ceased entirely, and a *reverse action* set in in the closing up of the wound.

The healing of a wound is more promoted by cellular radiation than by local inflammation. A healthy local inflammation is a necessity, but mainly to resist the absorption of septic matter from the wound. This resistance is simply a blocking up of the surrounding tissues of the wound, in which cellular radiation likewise is an important factor to effect this, but is characterized by the power of exudation instead of absorption. In my "Medical Consultation Book," I paid special attention in pointing out the effects of the albuminoids in protecting the system from the internal encroachment of toxic matter. The subject is one of great interest, and now to add another order of protection in the healing process of wounds, makes the study of self-protection in the animal economy a most interesting subject to the surgeon and the physician.

# COMMUNICATIONS.

## THE PRESIDENT'S ADDRESS.*

[ABSTRACT.]

JAMES F. HIBBERD, M.D., LL.D., RICHMOND, IND.

After thanking the Association for having conferred upon him the honor of presiding over its deliberations, and referring to the beautiful scenery and the scientific menu of the program, Dr. Hibbard spoke of the change of the time of the meeting, which had been rendered desirable in order that many of the State Societies would have an opportunity to act on the question of the revision of the Code of Ethics.

At every annual meeting the officers of the Association, particularly the Permanent Secretary and the Treasurer, have difficulty in appeasing delegates who are not received because the credentials presented by them have not been issued by a society entitled to representation in the Association. The law regulating this matter is plain, to wit: "The delegates shall receive their appointment from permanently organized State Medical Societies, and such county and district Medical Societies as are recognized *by representation* in their respective State Societies." Some of the State Societies are not representative bodies, and consequently this constitutional provision cuts off all delegates from such States except those commissioned by the State Society itself. While this is the letter of the law, it is not the spirit that animates the organization of the Association. The constitution should be revised in this particular at least.

This trouble could be overcome either by a change in the constitution, or better, by a representation of every county society in its State Society. The plan of

*Delivered before the American Medical Association, at the forty-fifth annual meeting, held at San Francisco, Cal., June 5, 1894.

organization so long in successful and satisfactory operation in Indiana might serve as a paradigm. In Indiana the State Society and each county society is a legal corporation. This is not essential, but desirable. Then, every medical man ought to belong to a county or similar society, and thereby to their respective State societies, whence, for the asking, they can step through the portals of this Association, and find in the sections a department already organized into which they can enter, according to the tastes or qualifications, and where a member of any special organization will find himself in the midst of all the members of an Association whose tastes run parallel with his own, whether specialist or general practitioner.

When Dr. Geo. M. Sternberg was appointed Surgeon-General of the Army in May last, he made two innovations in the administration of the affairs of the office: 1st. In establishing an Army Medical School to give passed candidates for appointment to the Army, laboratory practice in bacteriology, sanitary chemistry and other essential instructions for military service. 2d. The position of attending-surgeon in cities having good facilities for medical improvement he filled with young men who were preparing for promotion. These changes did an excellent work, without additional expense to the government; the Museum and Library Building furnished the rooms, and the medical officers on duty in Washington did the teaching in addition to their regular work.

But the number of active young surgeons about Washington and other cities attracted observation, and led the Chairman of the Committee on Military Affairs to conclude there was a surplus of Assistant Surgeons, and in his report to the House he reduced the number from 125 to 90, inhibiting fresh appointments until the number shall be reduced. This recommendation has passed the House, and should it be approved by the Senate will greatly embarrass the Medical Service of the Army and in the end be a detriment to the country, because many military posts will have to depend on civil physicians for medical attendance, and in case of war these would not take the field, and the Army would be without trained medical officers, which would be as serious an evil as unskilled officers in any other department. When these facts were pointed out to the chairman of the committee by other members with better knowledge of practical military affairs, the chairman replied that no one outside of the Army Surgeons had complained, not a single medical society had claimed that an injury would result. Let the American Medical Association at once call the attention of Congress to the mistake threatened.

For twelve years the appropriation for the support of the Library of the Surgeon General's Office was $10,000, but the last Congress reduced it to $7,000, and the present Congress proposes to continue the reduction. This is a National Medical Library, open to and used by physicians from all parts of the country, and the possibility of finding at one place in this country the greater part of the literature on any medical subject has exercised a powerful influence on American medical literature and education. The library aims to obtain every medical book, periodical and report published in any country or language as soon as possible after its issue, and have it at once catalogued and indexed and made available for use. This requires about $7,500 annually. There are still between twenty and thirty thousand volumes of medical books, published years ago, required to complete its equipment to meet all calls made upon it. These volumes are out of print, and only to be obtained from second-hand booksellers and auction sales as opportunity offers, and will involve say $2,500 spent annually for perhaps ten years.

The desirability of supervision of public health by the general government has been recognized by this Association for many years and manifested in various ways. Four years ago a committee, with Dr. C. G. Comegys, chairman, was appointed to prepare a bill, and petition Congress on behalf of the Association to establish a Department of Public Health. This Committee has been continued, somewhat modified, and has reported annually to the Association. Last year the Association appointed another committee, with U. O. B. Wingate as chairman, to consult with a like committee of the American Public Health Association, which has for several years been engaged in an effort to induce Congress to enact a law placing the supervision of the public health in charge of the general government. Other organizations have likewise entered Con-

gress with similar petitions. However, it seems the sentiment of the executive and legislative departments of the government is such as to rob us of all hope of the establishment of a Department of Public Health within the remainder of the nineteenth century. A bureau of public health, with a commissioner as its chief within one of the existing departments of the government was apparently within reach of a united, harmonious, aggressive effort of the profession for a year or two previous to the enlargement of the power of the Marine Hospital service by the last preceding Congress, but the excellent work of that service has lessened the anxiety of the government and the public. The outlook at this time is not encouraging, but if the problems in silver, and tariff and national revenue should be speedily and satisfactorily solved, there might appear a ray of hope for a bureau within the life of the present Congress, provided the medical and sanitary professions would make common and joint effort in demanding it. At present there is no measure formulated in this behalf so worthy of support as the New York Academy bill, now in the hands of Congress. There is no question but strong opposition to this bill has been made by strong men, but the fitness of sanitary human nature for great things is such, that if the opposition to the bill present one better than it, its friends will accept, and if this bill sustains its present status under severest scrutiny, its opponents will join in urging its enactment into a law, and thereby vindicate characters at once wise and patriotic.

Vaccination and other forms of sanitation have prevented an epidemic of small-pox in this country for a generation, and the people have lost the fear of its contagion through ignorance of its nature while progressing, and its sequelæ if its victim survives. The disorders that sometimes follow the insertion of pure vaccine in a cachectic system, and the greater evils arising from the use of spurious or imperfect vaccine and careless vaccination, which are all open to the observation of the public and subject to amplification by cranks and the maliciously ignorant, cause a positive distaste for vaccination among a considerable portion of our population, and a carelessness about securing it on the part of a much larger number. These facts should inspire physicians and other sanitarians who are the custodians of the knowledge of the value of vaccination to redoubled activity in devising and executing popular methods of instruction as to the entire reliability of vaccination to protect from small-pox, as much so as small-pox itself, and that with pure vaccine inserted under proper conditions into the tissues of a person fit to receive it there is positively no shadow of evil, but a promise of good not surpassed by any other single measure of preventive medicine. Evidence accumulates that the undetermined conditions that conduce to the propogation of small-pox are now, and for at least two years have been, prevalent in this country, resulting in outbursts of disease more or less serious in various parts of the country, and too often leaving foci from which fresh infection is distributed. Let us abide in the hope that the Jenner centennial celebration, provided by this Association and to be a part of its exercises at the annual meeting in 1896, may bring out the boundless blessing of the discovery of the immortal Jenner in such wise that all men shall see and acknowledge its protecting power.

Two leading purposes the fathers of this Association had in view at its organization, demanding its serious consideration, were the elevation of the standard of medical education, and that the authority to decide upon the sufficiency of the qualifications of a candidate for a diploma should not rest with his teachers. Much has been done in advancing the extent and character of the collegiate instruction of medical students; the examination of candidates for diplomas is still conducted by the teachers who instructed them, as was done then, and is no more satisfactory to the thoughtful minority of the profession than it was then.

The progress of medicine in the immediate future must be along biologic lines, and it seems desirable that every medical college should have a chair devoted specially to instruction in biology. No one people, or class of people, can claim exclusively to have opened the way into the more primitive arena of nature. The physicists of all nations, botanists, zoölogists, anatomists, physiologists and their congeners have all participated in the progress. Schwan, Virchow, Ferrier, Jackson, Pasteur, Koch and Steinberg may be

mentioned, without prejudice to the labor, name or fame of their many coadjutors, as examples of what benefactors to our race scientists may become whose genius lifts them to a plane of investigation not covered by the curricula practiced in the medical schools of their day, and their distinction is due to their advanced study of biology.

The question of changing the constitution may be readily settled at this meeting by taking a vote to determine whether the voters present desire any change in the existing constitution. If the decision is against any change, the affair is concluded for the once. If the decision expresses dissatisfaction with the constitution as it is, the next question should be: Is the report of the committee of revision precisely what the voters want as a substitute? An affirmative vote here settles the matter, and a negative vote will call for amendments that will adjust either the existing constitution or the committee's substitute, until it conforms to the wishes of the delegates. This may be done without excitement and with a minimum waste of time.

With the Code of Ethics, also, even more than with remodeling the constitution, there is much warmth of feeling; and, as in that case, a little calm forethought will convince that a primary vote involving the question whether or not the voters want any alteration of the Code, may end further consideration of the subject without excitement, confusion or over warmth of feeling, by a decision to let the Code stand as it is, and a contrary decision will call for further procedure, as recited for the completion of an amended constitution.

## NEW METHOD FOR REDUCTION OF FRACTURES OF THE LOWER END OF THE RADIUS.*

THOMAS S. K. MORTON, M. D.,† PHILADELPHIA.

The particular method of reducing fractures of the lower end of the radius, to be described, has proved so satisfactory during the past few years in my services at the Pennsylvania and the Polyclinic Hospitals and elsewhere, and in the hands of others to whom I have from time to time demonstrated it, that I now feel justified in giving to it wider publicity. The method is as follows:

The surgeon stands in front of the patient and interlaces his fingers beneath the supinated wrist and palm of the injured member, so that his two index-fingers lie parallel crosswise beneath the lower end of the upper fragment of the radius. The palms of the surgeon's hands are then closed in upon the thenar and hypothenar portions of the patient's hand respectively, while the surgeon's thumbs rest parallel lengthwise upon the upwardly displaced lower fragment of the radius. The parts are thus firmly grasped by the surgeon while the following movements are made: The patient's wrist is excessively extended by carrying his hand upward. When the hyper-extension has thus been secured the surgeon makes powerful traction upon the wrist in the line of hyper-extension. While this traction is maintained the hand is suddenly carried into full flexion, and at the same time powerful downward pressure upon the upwardly displaced lower fragment of the radius is made by the surgeon's thumbs opposed by the interlaced index-fingers beneath the lower end of the upper fragment.

The excessive extension of the first portion of the movement has always, so far in my experience, loosened or disentangled the displaced lower fragment, while the subsequent traction, flexion, and direct thumb-pressure have not yet failed to accurately force the lower fragment into its proper position. Separated epiphysis of the lower end of the radius is likewise easily reducible by this manipulation. For comminuted or complicated or very

*Read before the Philadelphia County Medical Society, May 9, 1894.

†Professor of Surgery in the Philadelphia Polyclinic; Out-patient Surgeon to the Pennsylvania Hospital; Assistant Surgeon, Orthopedic Hospital.

oblique fractures extension and moulding alone are called for in most instances.

Anæsthesia is unnecessary for making a single effort at reduction by the proposed method. The patient does not anticipate what is coming, the two movements are made with lightning-like rapidity in a small fraction of a second, and, in nearly every case, perfect reduction has been accomplished before the patient realizes that he has been hurt. Should the manipulation fail to secure perfect reduction at the first attempt, I would not repeat the manœuvre until anæsthesia had been induced, for the pain of repeating it would be intolerable. Failing in one effort, then, I would etherize and try again, first, this, and afterward, if necessary, any other method that seemed advisable to secure perfect reduction. But thus far in cases that have been seen within a week of the accident I have never had to anæsthetize since evolving the method mentioned; all have been reduced at the first attempt.

In cases older than one week, with displacement persisting, I anæsthetize before making any effort at reduction. The new method may then first be resorted to, and will often be found the best means of performing both refracture and reduction.

For making a diagnosis I have also found a modification of this method most useful. If the surgeon will take the hand and wrist in which fracture is suspected into his hands, as above described, and, while the thumbs press firmly upon the lower end of the radius or first row of the carpus, make a series of gentle, quick, short flexions and extensions of the joint—rocking it through an arc of perhaps 25 or 30 degrees above and below the forearm as a horizontal plane—he will be astonished at the ease with which crepitus of the bones of the joint and of any small or large bony or cartilaginous fragment will be elicited. And, best of all, the diagnosis of these obscure fractures about the wrist can thus, after some practice, be brought out without giving unbearable pain to the patient. Indeed, I have often this way, by the most gentle and practically painless manipulation, been able to clear up the nature of intricate injuries about the wrist.

By practicing the method upon a normal wrist a sufficient degree of expertness can readily be acquired; by it joint crepitation can be brought out in any wrist. It is well, however, not to practice too much or too often upon the same extremity, as excessive stirring up of the joint contents might originate a synovitis.

In conclusion, the writer desires to say that he will be gratified to have reports of the experience of others who may be tempted to employ the method here put forth.

### Chronic Bronchitis.

Codliver-oil. During twenty days of the month let the patient take a tablespoonful of the following solution:—

℞
Arseniate of sodium..... gr. iss.
Iodide of sodium..... ʒiiss.
Water..... ʒix.
M.

Every day give four of the following capsules:—

℞
Terpine,
Eucalyptol.....āā gr. iij.
M.

When there is dilatation of the tubes with fetid sputum, inhalation should be made every second hour with

℞
Eucalyptol ..... ʒj.
Alcohol (90 degrees)..... ʒiij.
Water..... ʒvj.

Every day the following potion should be taken:—

℞
Hyposulphite of sodium..... ʒj.
Gummy julep..... ʒiiss.
M.

Every day four of the following pills should be administered:—

℞
Beech-wood creasote,
Terpine,
Iodoform..... gr. ¾.
M.

---

### Capillary Bronchitis.

*In the Child.*—In the beginning give an ipecac emetic. Make counter-irritation to chest. Every two hours give a teaspoonful of

℞
Acetate of ammonium..... ʒss.
Malaga wine..... ʒx.
Peppermint water..... ʒv.
Syrup of orange-peel..... ʒij.
M.

*In the Aged.*—Dry cup the chest every two or three days. Let the patient take every two hours a tablespoonful of

℞
Extract of cinchona,
Extract of kola.....āā ʒj.
Old brandy..... ʒx.
Simple julep..... ʒiiss.
M.

In alternation with the preceding mixture administer, every second hour, a teaspoonful of the following cough-mixture:—

℞
Syrup thebaic..... ʒiss.
Syrup of belladonna..... ʒvj.
Cherry-laurel water..... ʒi¼.
Hydrolate of linden..... ʒx.
M.

# ASCITIC DISTENTION OF THE ABDOMEN MISTAKEN FOR PREGNANCY.*

T. RIDGWAY BARKER, M. D.

The following case is reported in order to prove the importance, if not absolute necessity, of making a careful and thorough examination of all women pregnant, or supposed to be, before committing ourselves to a positive diagnosis.

In June, 1891, I first saw the patient, Mrs. M. N.; she was then eighteen years of age, white, mother of two children. There was no history of any miscarriages. Her general health was good and condition favorable for the development of the product of conception which she believed was present, menstruation having ceased in October of the preceding year. Inquiry elicited the fact that her menstrual flow up to that time had been perfectly regular and unaccompanied by pain. Morning sickness proved very annoying for the first three months, but later passed away.

From inspection, abdominal palpation, and digital vaginal examination, the patient was judged to be some six months pregnant, and the date of confinement set for the early part of August. On July 27th, I confined Mrs. N., delivering her of a fine male infant which presented by the vertex.

Labor was accomplished without incident or difficulty, and the lying-in period presented no symptoms suggestive of any organic lesion of the kidney. In fact, it is fair to assume that at that time there did not exist any disease of that excretory organ.

The puerperant's pulse was 72 immediately after delivery, but the temperature was not taken.

I visited Mrs. N. for ten days, when attendance was discontinued, the patient being able to be up and move about her room. Mrs. N. was not seen again by me for over two years, when she called at the dispensary and stated that in the first week in January, 1893, she had suffered from a miscarriage.

The product of conception she passed she presumed was about three months' gestation. The cause of its expulsion I was unable to determine, but ascribed it to a catarrhal condition of the endometrium.

*Read before the Philadelphia County Medical Society, May 9, 1894.

While carrying the embryo she had a slight flow of blood each month which she imagined was her menstrual flow, though she remarked at the time it was of shorter duration and more scanty than usual.

The patient failed to return on the day specified and was not seen again until March 6th, of this year. She stated on presenting herself at the clinic that some months after her last visit to the institution she imagined herself to be in the family-way again and called to see a physician. The doctor, she reported, told her that he believed her view to be correct as to her condition, and that he considered her about four months pregnant, and that her confinement might be expected in December. No vaginal examination was made by him, however, nor did he palpate the abdomen, but based his diagnosis simply upon the results of inspection of the uncovered ventral region.

The breasts were exposed on this occasion and were found to be large, full and globular. The veins were prominent and the areolæ well defined. Milk on pressure, she stated, exuded from the nipples as in former pregnancies. At this time her feet were considerably swollen and the œdema tended to extend up the limbs.

Morning sickness was entirely absent. Leucorrhœa was present, but no remedies were directed toward its treatment. At each monthly period, the patient stated, she had a scanty flow of blood, but thought nothing of it as she had much the same discharge in a former pregnancy. She did not again call on her physician, as she felt no anxiety, having passed through three confinements without difficulty.

When I saw Mrs. N. it was March 6th, nearly three months, I learned, after the date of her expected confinement. She was then suffering from nervous prostration incident in a large measure to the worry occasioned by her delayed labor, she was afraid something was the matter.

Her abdomen, she stated, felt different from what it had ever done before. Inspection of the breasts showed them to present what one might almost say was a condition typical of pregnancy. Even the colostrum exuded on pressure from the orifices of the lactiferous ducts. On

inquiry as to whether she felt fœtal movements, she replied that she did at times, but very slightly. No bearing-down sensations, however, or pain had been experienced.

A glance at her abdomen showed markedly that it was not as prominent as one would have reason to expect it would be in a multipara at full term.

On request, Mrs. N. consented to lie down on the sofa in the dorso-recumbent position, and as she proceeded to do so I was impressed with the fact that the abdomen at once became flattened and broader. This made me suspicious as to the presence of a fœtus, and I at once proceeded to palpate over the region of the supposed pregnant uterus. The abdominal walls were flabby, and the intestines were in contact with them in front but not on the sides. Carrying the examining hand downward toward the pubis I found the uterus wholly within the true pelvic cavity. It seemed about normal in size, and there was elicited no sense of tenderness.

Evidently there was no full-term fœtus in that woman's abdomen. Having secured the patient's consent to a digital vaginal examination, I proceeded to make the same, subject to the rules of asepsis. Inspection of the external genitalia presented nothing characteristic. Passing my index finger up the vaginal canal to the cervix, I found it to be elongated, hard and fissured. The os was small, and from it could be felt escaping a mucous discharge. A sound was passed into the uterus and its cavity made out to measure some three to three and one-half inches.

Search for shreds of membrane or other products of a late conception failed to be productive of any result. The distention of the abdomen was undoubtedly ascitic, and not due to a natural growth of a pregnant uterus.

Further inquiry disclosed the fact that not only had there been for several months œdema of the lower extremities, but also swelling of the face as well. This was especially noticeable about the eyelids.

The urine was passed in large quantities and very frequently. It was of a pale yellow or lemon color; sp. gr. 1010; of acid reaction. No albumen present. Sediment composed of mucus. There had been for many months a gradual but none the less persistent loss of flesh.

The eyesight was very poor, so much so that the woman could scarcely read the newspapers. A kind of mist, as Mrs. N. expressed it, floated before her eyes. Headache was not a troublesome symptom nor was any amount of pain referable to the loins made out. Sleep was troubled and the patient not infrequently awoke in a fright.

Inquiry as to the health of her parents brought forth the statement that her father died, under forty years of age, suddenly in the street, and that he had for some years suffered from dropsy. Her mother was still living and enjoyed the best of health. Mrs. N. has no brothers or sisters. It is not my purpose in this paper to enter into a discussion as to the nature of the kidney lesion, but to lay special stress upon the error in diagnosis which resulted simply from a failure to appreciate and apply the golden rules of obstetrics governing the diagnosis of pregnancy. Had the first practitioner who saw this woman not limited his examination to the breasts, but extended it to the abdomen and supplemented the same by a digital vaginal one, he would not have fallen into the error of diagnosticating a case of kidney disease with ascites one of pregnancy.

The case is a typical example of a "snap" diagnosis and only too clearly proves that the thorough way, which calls for inspection, palpation, ausculation, and digital vaginal examination, though more disagreeable, less brilliant, and tedious, is the only safe and satisfactory one in the long run.

Moreover, we see how little dependence is to be placed upon the patient's statements as to her subjective symptoms. Mrs. N. unhesitatingly told me that she did feel fœtal movements, though they were slight, on the occasion of my first visit, three months after the date fixed for her confinement.

Examination, however, proved her sensations to be purely imaginary. She believed herself pregnant, and therefore, knowing that she should have "quickened," she believed that she did recoguize fœtal movements.

While the mistake in diagnosis in this case did not result disastrously, yet it might under some circumstances have been made the basis of a suit for damages.

One may occasionally make some brilliant "snap diagnoses," but he may rest assured disaster will surely follow if this course is pursued for any length of time.

# TRANSLATIONS.

## THERAPEUTICAL SUGGESTIONS FROM FOREIGN JOURNALS.*

### ICHTHYOL IN GONORRHŒA IN WOMEN.

Dr. Jullien (*La Sperimentale*, No. 9, 1894) in the treatment of gonorrhœa in women speaks highly of the local application of a 10 per cent. solution in glycerine, upon a tuft of absorbent cotton twisted around a metallic staff, to the urethra. It is repeated every day and with this procedure he has obtained the best of results, in ordinary cases. A tampon with this same solution may be placed into the vagina to prevent diffusion of the gonococcus.

### THE IODIDE OF RUBIDIUM AND THE IODIDES.

Dr. C. Vogt (*La Bulletin Medical*, No. 39, 1894) at a recent meeting of the Therapeutic Society of Paris, reported a case of syphilitic headache, which uninfluenced by the iodide of potash, yielded rapidly to the iodide of rubidium. He has a favorable opinion of this iodide though it is three times as expensive as the potash salt. Its taste is not pronounced and it is well tolerated. In cases where an iodide is indicated and the potash salt is not well borne, the iodide of rubidium may be tried, especially where the treatment must be prolonged. In the discussion which followed, Prof. C. Paul thought that rather than point out the inconveniences of a new remedy one should try to fix its sphere of curative action and its indications than to make it replace another remedy. The iodide of sodium, which was heralded some years ago as a substitute for the iodide of potash has been demonstrated to be decidedly inferior, both in syphilis and arterio-sclerosis. The iodide of potash is certainly a very disagreeable drug, but it cures, and that is the necessary feature. In some cases it is heroic, but its curative action surpasses its few inconveniences. For example, in aortic affections and especially in atheroma, it will lengthen a patient's life by years, where the sodium salt will be insufficient. In these cases he continues it until the kidneys refuse to tolerate it, when he replaces it with the iodide of strontium. Besides, there are several kinds of syphilitic headache; that of the secondary eruption is easily cured by a few grains of the iodide of potash. He has found the classic measures of combating the inconveniences of the iodide—belladonna, opium, etc., of no service. A diuretic vehicle, as an infusion of corn silk acts best, he has found. Dr. G. Bardet thinks that the association of potash with iodine is essential in syphilis. Dr. Courtade, in twenty patients, has found the iodide of lime better tolerated than the potash compound, but it is less efficacious. Some patients are very intolerant though the majority only show a little or some lachrymation. Dr. R. Blondel stated that if taken in a good deal of water with an equal quantity of the bicarbonate of soda, it is well borne by the most intolerant. Prof. C. Paul also prescribes it in a syrup of coffee, three gms. of the iodide to five hundred gms. of syrup. Even in aortic affections this preparation is well tolerated.

### ICHTHYOL IN PROSTATITIS.

Dr. Scharff (*Journal de Médecine de Paris*, No. 19, 1894) in those cases of posterior urethritis where the prostate is involved, swells, becomes painful, and may increase in size so as to obstruct the large intestine, has found from an experience extending over forty cases, that a ten per cent. solution of ichthyol, in water, of which the patient injects three or four times a day a syringeful into the anus, will give good results. After two or three days of this treatment the patients, who, before could scarcely drag themselves to the consulting room, then walked with ease and passed their stools without difficulty. Rectal examination would reveal the prostate, which before was swollen and painful, to have been reduced to its normal dimensions and painless to contact. He ascribes these favorable results to the action of ichthyol as a sedative contractor of blood vessels, and an absorbent of exudates. Its favorable influence in gynecological diseases is well known.

*In charge of the Translator, F. H. Pritchard, A. M. M.D.

### COLD COMPRESSES IN DISEASES OF THE CHEST.

Dr. Legendre (*Revista de Ciencias Medicas de Barcelona*, No. 8, 1894) in pulmonary affections when there is active hyperemia, prefers wrapping the chest in cold compresses to the ordinary revulsive measures; especially in children, where this procedure may be continued as long as desirable and repeated as often as necessary. Rendu has employed them since 1884 in severe broncho-pneumonia with favorable results. Richardière has used them in sixty cases of broncho-pneumonia in the Hôpital Trousseau, and with satisfactory results. Legendre regards it as the most simple, rapid, and at the same time the most efficacious measure. He has kept children wrapped in these cold compresses for eight days. They act upon the kidneys, keep them well open, and favor diuresis and diaphoresis.

### TREATMENT OF EPILEPSY.

In the *Journal de Médecine de Paris*, No. 19, 1894, the following treatment of epilepsy is recommended:

Preventative treatment: Avoid mental overwork or fatigue, sudden changes of temperature, a too warm or too cold temperature are both unfavorable. Alcoholic beverages, coffee, tea, and too hearty meals are contraindicated. Regulate the bowels, for constipation may bring on an attack.

Treatment during the attack: Place the epileptic upon a bed with his head upon a low pillow, his neck freed from compression or constriction, and protected from injury during violent contractions. If the attacks repeat themselves frequently during the day, one may administer a rectal injection of chloral either alone or associated with the bromide:

℞

| | | |
|---|---|---|
| Chloral..... | | |
| Bromide Potash..... | aa 2 | o (grs. xxx). |
| Yolk Egg..... | No. 1 | |
| Water..... | 200 | o (ʒvjss). |

Administer during an interval.

In traumatic epilepsy surgical measures are the only radical treatment. Traumatic epilepsy may be confounded with cerebral syphilis, and hence the mixed treatment may be tried: the iodide of potash and mercurial inunctions. Intra-muscular injections of the iodide will also render signal service.

Lemoine administers as a reconstituent and nervous sedative the bromides and the phosphates. During the first few months he employs mercurial frictions and the iodide of potash; the next two months the following:

℞

| | | |
|---|---|---|
| Bromide Potash..... | 25 | o (ʒvj). |
| Phosphate Soda..... | 20 | o (ʒv). |
| Syrup Bitter Orange Peel..... | 25 | o (ʒvj). |
| Wine..... | 250 | o (ʒviij). |

A wineglassful after each meal.

In menstrual epilepsy one may administer, every three days, the following powder:

℞

| | |
|---|---|
| Antipyrine..... | 70 (grs. xj). |
| Bicarb. Soda..... | 25 (grs. iv). |

If at the same time there is a marked weakness of the pulse, one may prescribe:

℞

| | |
|---|---|
| Powdered Digitalis Leaves..... | 05 (gr. j). |
| Bicarb. Soda..... | 25 (grs. iv). |

Sufficient for one powder.

*Administration of the Bromides.*—Lemoine claims that the association of hyoscyamine with the bromides forms one of the most efficacious remedies in convulsive states. His formula is as follows:

℞

| | | |
|---|---|---|
| Bromide Potash..... | 30 | o (ʒvijss). |
| Bromide Sodium..... | | |
| Bromide Ammonium..... | aa 15 | o (ʒiv). |
| Crystall. Hysocyamine..... | o | 015 (gr. i-5). |
| Water..... | 1 | litre (o. ij). |

If one should wish a larger dosage, the following then is serviceable:

℞

| | | |
|---|---|---|
| Bromide Potash..... | 15 | o (ʒiv). |
| Bromide Sodium..... | | |
| Bromide Ammonium..... | aa 8 | o (ʒij). |
| Crystall. Hyoscyamine..... | o | 015 (gr. i-5). |
| Water..... | 200 | o (ʒvjss). |

A tablespoonful every evening.

If symptoms of bromism set in, the bromide of gold, which is better tolerated, may be substituted, in the following formula:

℞

| | | |
|---|---|---|
| Bromide Gold..... | o | 20 (grs. iij). |
| Water..... | 550 | o (ʒxvij). |

Every tablespoonful of this solution contains two mgms. ($\frac{1}{30}$ gr.) of the bromide of gold; two teaspoonfuls a day. Lemoine advises taking the bromides either in milk or beer to mask the taste. The borate of soda has been used in epilepsy especially in the diathesic variety.

[Ch. Féré has recently published a paper on the untoward effects of borax when employed as an antiepileptic remedy.—*Trans.*]

### For Neuralgia.

℞

| | |
|---|---|
| Ferri tartarati..... | gr. ij. |
| Quininæ sulphatis..... | gr. ij. |
| Acidi tartarici, | |
| Extract nucis vomicæ..... | ãã gr. ss. |

Misce et fiat pilula. Sig. Take one three times a day.

## EDITORIAL.

### PUBLIC HEALTH MEASURES—ARE THEY PERFECTED?

Says the *Independent*:—So much is printed in the daily and weekly journals of the land on the Prevention of Disease, and so zealously is the cause advocated by the most advanced physicians, that people are beginning to ask what there will be left for the doctors to do after they have succeeded in teaching us how to avoid all the kinds of decimating bacteria, and after they have taught us how to live truly hygienic lives in perfectly sanitary homes. Certainly these various measures supply us with the best possible armor against the assaults of disease; but there is no fear that as the lay mind becomes more perfectly imbued with intelligence, the physician's occupation will wither and fade. The more a man knows of the structure of the body, the more clearly will he realize that he takes a great risk when he invites an ignoramus to pronounce his crude judgments on, and thrust in his harsh remedies among, the delicate chords of this harp of a thousand strings; so that now on every hand there is a growing demand for a higher education and a more thorough training for our medical men.

This is all very well. The medical profession does not yet see the need of looking around for other employment. Indeed the question has not entered into calculation, for while there is abundant evidence of the great advances in the well-being of mankind, made directly by the efforts of scientific medical men, none are better aware of the fact that sanitary medicine has made but a beginning than are the physicians themselves. The greatest improvement in public health is shown in those nations where the matter of public sanitation and hygiene is committed to the care of the central government. The people of the United States are strangely lagging behind the governments of Europe in recognizing the necessity for systematic supervision of the public hygiene and for the enforcement of health measures by the authority of national law. It is true, that in the national quarantine duties of the Marine Hospital Service, established to meet a threatened

emergency, the United States has a corps of effective, energetic scientists not to be surpassed anywhere; but, the the duty of the Marine Hospital Service is to afford protection from danger from without. Apart from this the care of the public health depends upon the governments of the various states. In consequence we have some painful contrasts. Some of the states have established Boards of Health, with ample provisions for effective organization for the work, and endued them with sufficient powers to enforce such measures as they may find necessary for public welfare. Other states have established similar Boards of Health, but have neglected to render them effective. Still other states have not as yet evolved sufficiently to appreciate the advantages of public hygiene, while at least one state has made the woeful blunder of abolishing its State Board instead of strengthening its hands.

Contrast the recent situation in two of our Southern States. A year ago small-pox made its appearance in that portion of Virginia projecting between Tennessee and Kentucky. Virginia has no health boards in that region, no means of restraint or quarantine; but the intelligent and wide-awake health officers of Tennessee were instantly on the alert. In Chattanooga, November 7th, 1893, a case was reported. At once the State Board of Health sent out a warning "leaflet" to every county and town health officer in the State, giving minute directions for preventing and controlling the disease, and, as the secretary truly says, "this course disarms terror, prepares the public to await results with coolness, and enables health officials to have inspectors, nurses, hospitals and all other appliances now required by sanitary progress, in readiness." Whenever a fresh outbreak occurred the warnings were repeated, and the press throughout the State united in calling for vigilance. The secretary, who enthusiastically worked through a great many years of public apathy, now cheerfully adds:

"At no period since the establishment of the State Board of Health has so systematic and thorough co-operation prevailed with local workers. These are rapidly learning the great advantage to them of information, and authority emanating directly from the central health department."

There were but a few scattered cases in the State, in spite of its nearly half a million of colored people, who have been regarded as peculiarly liable to the infection, as they are crowded together in the cities and towns.

Georgia did not believe in such foolish notions and abolished her State Board. How colossal and fatal was this blunder was demonstrated last fall in the paralyzing scourge of Yellow fever in her principal seaport town. It was a matter for congratulation not only for that city and state but to the entire country that there was organized federal help for her through the United States Marine Hospital Service.

Small-pox this past winter has been more or less prevalent throughout portions of the United States, but it has failed to reach the proportions of an epidemic, because of the watchful care and effective provisions of the various health authorities brought in contact with it. In 1872, an epidemic of small-pox swept around the world. It found nations which had been free from its ravages so long that they had ceased to fear it, and had become careless of providing against it. Vaccination had gone out of fashion. The epidemic of small-pox promptly re-established it in public favor, and many countries enacted laws with severe penalties for compulsory vaccination. The same conditions hold true to-day, though greatly modified by increased intelligence and knowledge. But we yet hear the old

objections and superstitions against the protection of the public by vaccination, compulsory if necessary. The almost total absence of small-pox from the German Empire, and its entire suppression in the army where vaccination and re-vaccination at stated periods is compulsory, show that intelligence and organization have achieved, and Holland handsomely swells the catalog. Between the years of 1870 and 1873 there were 20,575 deaths; but a stringent law for compulsory vaccination being enforced, there was but one death throughout the kingdom in 1890.

It is well to bear in mind that a single vaccination, however effective temporarily, probably does not confer life long immunity, and the more recent authorities are inclined to recommend multiple inoculations.

## ABSTRACTS.

### INTESTINAL OBSTRUCTION DUE TO OCCLUSION OF THE ILEUM BY PRESSURE BAND.

Robert Jones reports (*Br. Med. Jour.*): On Tuesday, December 19th, 1893, I was asked by Dr. Hugh Shaw to examine a case of intestinal obstruction. The patient was H. A. S., a milliner's apprentice, aged 14. On December 7th, whilst at her work, she was suddenly seized with violent pains shooting across the abdomen in the line of the umbilicus. She vomited several times on her way home, and, on her arrival, went to bed. A little later her bowels were freely moved. This attack was not regarded seriously by her family, and as the acute symptoms seemed to abate domestic antidotes were relied on. For two or three days she remained in considerable pain, with occasional sickness, when her mother administered a copious soap and water enema. This gave temporary relief by emptying the large bowel of gas, but the pain and vomiting returned with severity, and on December 13th, Dr. Shaw was sent for. He found the patient in great pain, with moderate distension, good pulse, moist tongue, and normal temperature, and thinking it best to act conservatively, he gave appropriate directions with a view to lessening intra-abdominal pressure and to relieving pain. All the symptoms, however, increased, the pain becoming intense, and the vomiting more and more frequent, while the temperature remained at about 102°F. On December 15th, the vomiting became fæculent, and from that time until December 19th, when I first saw the patient, nothing was retained. She then presented symptoms of impending collapse—a small quick pulse, dry tongue, a haggard look, listless demeanor, and rapid shallow respirations. The abdomen was distended and tympanitic, especially round the middle line. Fæculent material was being vomited every few minutes, thirst was intense, and there was pain on pressure over the right side of the abdomen. The patient, despite all this, was mentually alert, and took an intelligent interest in her affairs.

I was told she had been a well-developed girl, and well nourished, and had never needed a doctor in her life. For the last four years, however, she had been subject to what were called bilious attacks, the prominent symptom of which was vomiting, which lasted for one or two days, and was often accompanied by pain and sometimes by diarrhœa. For twelve months she had had considerable pain in the epigastrium, which came on directly after food and often resulted in sickness. About two years back she suffered great pain in the right side on exertion, more particulary if she attempted to walk quickly or to run.

We decided, in view of the previous history and the patient's condition, that laparaotomy should be performed without delay. That evening a median incision 3 or 4 inches long was made below the umbilicus, and the cavity of the abdomen exposed. Distended gut, pinkish in color and dotted with flaky lymph, pre-

sented. On introducing my finger, the coils of intestine were sufficiently adherent to each other to require care in separating them. I was able quite easily to recognize the cæcum, and found it collapsed. There were also in the pelvis a few coils of empty small intestine. By very gently following this without exposing bowel, I felt a distended loop of intestine, which was carefully brought towards the wound. Immediately below I found a band about half an inch broad, which obviously compressed the intestine. I did not feel justified in accurately defining its limits, but it stretched transversely across the gut from the direction of the right kidney. The bowel was not kinked, but was sufficiently pressed upon to be quite occluded. Ligatures were applied and the strand severed. The wound was adjusted, and the patient placed in bed. Here a somewhat dramatic incident occured. It was found that owing to a blunder a sponge was short. After a brief and fruitless hunt, in basins, pails, and *debris*, I decided to reopen the abdomen. Luckily this was done, and the sponge recovered from within.

It is needless to report the subsequent events at length. The operation, which only lasted twenty minutes, had but a very slightly depressing action on the patient. The vomiting once and for all completely ceased. The temperature was normal next morning, and only once again, on the third day and for a few hours, rose to 101°. On the second day (December 21st) there was a suspicion of the passage of flatus; on December 22nd, a certainty of it; on December 24th, the tongue became moist, and the bowels were opened at 3 P. M. and 4 P. M. The first motion, about 4 ounces, was similar to the vomit, the second consisted of mucus. Shortly following the evacuation there were sharp abdominal pains, and the tongue became a little dry. From this time on the bowels were frequently opened, and the patient rapidly got well.

There are a few points of interest to which I would wish to allude. 1. The operation was performed on the twelfth day of obstruction and during considerable abdominal distension. I have often expressed an opinion that it is useless and dangerous to hunt for obstruction while peritonitis and distended gut are present, and that the indications are best met by a carefully performed enterostomy; opening of course a distended coil. The empty condition of the cæcum, however, together with the collapsed small intestine, pointed to obstruction high up—a condition ill-suited for enterostomy. Again, although the obstruction was high up, fæcal vomiting did not appear for eight days, and this suggested that probably the obstruction, very incomplete at first, became more complete by distension from above, and that had care been exercised early the symptoms might have continued, as they had begun, to abate.

This opinion is fortified by the fact that the pain she complained of during exercise and hurry was over the neighborhood of the band, and that probably her frequent so-called bilious attacks emanated from the same source. Amongst the causes which deprive an early obstruction of a fair chance, next to cathartics, should be placed enemata, which, as Niemeyer pointed out years ago, induce peristalsis above as well as below the seat of obstruction.

There was another symptom in this case which interested me, and that was the sharp abdominal pain which followed shortly after the anal evacuation. I have frequently observed this before. In one case, which was being treated expectantly, the patient died on the twentieth day, four hours after the relief of obstruction, having endured sharp abdominal twinges. In another case after the relief of a very simple hernia, an evacuation of bowel took place, followed by collapse and death.

## THE LOUISVILLE MEDICO-CHIRURGICAL SOCIETY.

*March 9, 1894.*

STENOGRAPHICALLY REPORTED BY C. C. MAPES.

Discussion of Dr. T. L. McDermott's essay continued from THE REPORTER of June 16, 1894, on

APPENDICITIS FROM A MEDICAL STANDPOINT.

(See page 813)

DR. A. M. CARTLEDGE: The more I study the subject of appendicitis the more I find to be hnown in connection with it. When I I thought, five years ago, that I knew a great dral about appendicitis, I find that I knew very little about it, and I want to say once for all that my views on the disease, both as to pathology and treatment, time of operation and diagnosis hnve been the subject of constant change. Even a year ago had I been interrogated as to the nature of the trouble where a patient had recurrant attacks of pain and a lump in the right iliac region, with temperature of 101°, I would have said "catarrhal appedicitis" and advised agaiust operative procedure, believing that the case would probably get well. If evidences of pus were present I would have waited until I thought there were anterior peritoneal adhesions to serve as protection to the general peritoneal cavity, then go ahead and open the abscess and drain it, removing the the appendix. If asked the question what I would do in the perforative type, where rupture had occurred primarily, with the possibillities of pus in the abdomen, I would have answered just as I would at the present time, that operation is imperatively demanded at once. I now believe that all cases of appendicitis can be so diagnosed without question, should be operated upon. As you all know I differ with the majority of surgeons in regard to the pathologic classification of this affection. For instance look at the discussion of the subject to-night, what variable course it leads, Here is a gentleman who says, from what knowledge we have of the clinical manifestations and clinical history of these cases that there is no material difference between appendicitis and the older terms of typhlitis, perityphlitis, etc., and further makes the statement that there is no case of appendicitis that ought to be operated upon; that he would not advise operation in any case. If this does not call for some more definite classification of this disease, I cannot conceive of anything that would do so more than this discussion to-night. To revert to the specimens shown at the last meeting of this Society, I selected three specimens, illustrating three types of the disease. My object in presenting these specimens was to try and throw some light on the pathology and classification of the disease. In the specimen Dr. Anderson has mentioned, which was a case operated upon the day of the meeting, there was a distinct stenosis about one-half inch from the base, the result of cicatrization of former inflammation; there was a history of several attacks of undoubted appendicitis; the appendix was found coiled up behind the cæcum and adherent, enormously distended with liquid fecal matter and pus. The appendix was slit open in order to show the stricture. It was a typical case of so-called catarrhal appendicitis, a condition which I claim cannot be recognized and does not exist. I claim that all lesions in this situation, sufficiently well-marked to be denominated appendicitis, are primarily ulcerative or perforative in type. Those cases heretofore called catarrhal appendicitis I am confident were ulcerative in character, which led to stenosis at some portion of the lumen of the appendix. It was to illustrate this point particularly that I exhibited the specimen.

It seems that the point which has attracted the most attention in regard to the specimen presented, was the pathological condition, and this is the very point that I regarded as being the most apparent. There was plainly stricture, the continued contraction of which will eventually lead to either one of two pathological terminations—complete stenosis with distal distension and rupture, or retention with infection and general septic inflammation of the appendix leading to necrosis and perforation. The case was operated upon before rupture had taken place, and the result shows the wisdom of such a procedure.

As to exploratory incisions being harmless —it is probable that they are not harmless, but by this means of confirming diagnoses we have been enabled to clear up a very wide field of surgery. Twenty-five years ago the greatest problem before the surgical world was the diagnosis of ovarian cysts, but matters are now so thoroughly understood that even the country practitioner is able to make the diagnosis without question. Since this

is true of exploratory incision in ovarian tumors, I see no reason why the same rule should not be applied in appendicitis to the end that we may better understand the pathology. In our present understanding we know that occasionally other conditions present pathological features which can hardly be differentiated. I remember having operated upon what I thought to be a typical case of appendicitis, which proved to be tubal pregnancy. The sac and contents were removed and the lady made an easy recovery.

The question of hernia following appendisectomy has been mentioned. Of course, we must admit that hernia is more common following any operation where the incision is made out of the median line, but I believe with the proper after-treatment this liability to hernia can be reduced to a minimum.

Dr. McDermott suggests that physicians ought to become more careful about advising operations for appendicitis. I heartily endorse this portion of his remarks, but the deduction he makes is entirely from the standpoint of observation. While a man's past experience is very valuable as a guide still it should not be entirely convincing. The probabilities are that men to-day are operating for appendicitis who a year or two ago would have advised against it. I cannot understand how a man can stand up and say that operation for this disease is not advisable and should not be performed in any case, when he has seen the abdomen opened, where the appendix has been found perforated and gangrenous, and the cavity filled with pus.

There is nothing that will regulate the operation for appendicitis, time for operative interference, etc., etc., save a better knowledge of the pathology of the affection. Treeves and some others quoted to-night, do not refuse to operate upon patients suffering with suppurative appendicitis, demonstrating very clearly that they recognize the necessity of surgical measures. The mistake, I think, that nearly all authorities make, is that they continue to classify the affection as "perforative," "ulcerative," and "catarrhal." As I have stated before, I fail to see how catarrhal conditions of the mucous membrane can produce symptoms which can be recognized in connection with the appendix, or by which the condition can be diagnosed. I claim that it is utterly impossible. Then the question might be asked to what can we attribute such symptoms? I say that the specimen I exhibited at the last meeting of this Society fully demonstrates to be an ulcerative, inflammatory condition, resulting in stenosis and distal distension and finally perforation and septic infection extending to the peritoneum and structures surrounding the appendix. From the anatomy of the appendix it will be apparent that a part of the caecal contents may be forced into it, and may again be discharged into the caecum. We know that fecal matter does not normally occupy the appendix, its contents being only a mucous secretion, and I take it when fecal matter is found it is *prima facie* evidence that the appendix or the door to its entrance is diseased. This is interesting in connection with the so-called cures of appendicitis by the administration of opium, etc. A man has an attack of what is diagnosed by the attending physician appendicitis. He is treated by the usual medical methods and recovers. Some time afterward he has another physician, and under similar treatment again recovers. Say he has six or seven such attacks, and is seen by as many different physicians, each of whom record it as a cure without operation. Finally he has a more severe attack, perforation evidently takes place; the patieut is referred to a surgeon, is operated upon, and dies. Of course the death is only recorded once and the case is recorded seven times as cured by medical treatment. Therefore statistics as quoted by our essayist, under these conditions would seem to be of little practical value. I am not inclined to believe that undoubted appendicitis is ever cured except by operative treatment. The appendix may become distended and, if the stricture is not complete, the contents may be discharged back into the cæcum, but it does not necessarily follow that the patient is cured, for the probability of future trouble is very great.

Another point: Microscopical examinations have proven that a great many of these cases are tuberculous in character, and I claim that we have no right to leave tuberculous structures anywhere in the body, because the patient is thus subjected to great danger of general tuberculous infection. The same thing is true of pus, no matter in what organ or structure it may be discovered.

When statistics are quoted to us that 95 per cent. of the cases of appendicitis recover spontaneously, they are certainly the first, second or third attacks, as I have before indicated. In other words it is the point of observation from which you look at them. While Dr. Anderson and the other speakers may have treated cases of undoubted appendicitis which recovered, and some of which may still apparently remain well, it is no sign that they may not yet develop a perforative attack and die. I believe that when the appendix is once diseased, where there is ulceration it will be followed by stenosis and the patient will be liable to subsequent attacks, any one of which may result fatally. Mortuary statistics show that such deaths result from peritonitis, while I believe the facts in the case would show that the patients died of appendicitis. There is no doubt in my mind

that ninety-five out of every hundred cases of peritonitis in the male are the result of appendicitis.

One word in regard to the diagnosis: Rigidity in the right iliac region; localized pain, acute in character; elevation of temperature over 100° F. and vomiting, are indicative of appendicitis ninety-eight times out of a hundred, and demand operative interference. In the other two per cent. the mistake is pardonable for the good done the ninety-eight.

DR. W. L. RODMAN: He who says that operation should *never* be performed for appendicitis is certainly wrong; on the other hand, those who say that the *great majority* of these cases should be operated upon, are as far from the truth. I am satisfied that the tendency in this country is to operate too much for this affection. I cannot understand how any man can say that there will *not be found* cases of gangrenous appendices that ought to be operated upon; cases that cannot be relieved in any other way. I believe the *middle* course is the safer. Further, I believe in the English practice of operating between attacks, as we find our patients in the best condition to withstand a laparotomy.

## PROCEEDINGS OF ASSOCIATION OF AMERICAN ANATOMISTS.

The sixth annual meeting of the Association of American Anatomists was held in conjunction with the Congress of American Physicians and Surgeons, in Whashington, D. C., May 29th to June 1st, 1894.

The Secretary reported that Dr. Chas. B. Ewing, Assistant Surgeon U. S. A., and Dr. F. C. Schaefer, Professor of Anatomy in Chicago Medical College had resigned, and that three members had died, namely: Dr. Wm. Lee, Professor of Physiology, Columbian University, Washington; Dr. Wm. B. Towles, Professor of Anatomy and Materia Medica, University of Virgina, and of Anatomy, University of Vermont; and Dr. Corydon C. Ford, Professor of Anatomy and Physiology, University of Michigan.

The following new members were elected: Dr. John A. Boger, Assistant Demonstrator of Anatomy, University of Pennsylvania; Dr. H. B. Ferris, Assistant Professor of Anatomy, Yale University; Dr. Robert L. Greene, Professor of Anatomy, University Medical College and Western Dental College, Kansas City, Mo.; Dr. Wm. Keiller, Professor of Anatomy, University of Texas; Dr. Joseph Leidy, Assistant of Demonstrator of Anatomy, University of Penna,; Dr. Mary B. Moody, New Haven, Conn.; Mr. Robert O. Moody, Yale Medical School; Dr. Chas. D. Smith, Professor of Physiology, Bowdoin College; Dr. Wm. O. Stillman, Albany, N. Y.; Dr. W. C. Woodward, University of Georgetown, Washington, D. C. Sir Wm. Turner, of London, was elected an honorary member.

The officers elected for the ensuing term were: Dr. Thos. Dwight, of Harvard University, for President; Dr. B. G. Wilder, of Cornell University, first Vice-President; Dr. F. J. Shepherd, of McGill University, Montreal, second Vice-President; Dr. D. S. Lamb, Army Medical Museum, Washington, Secretary and Treasurer; Prof. C. L. Herrick, Denison College, Granville, Ohio, delegate to the Congress of American Physicians and Surgeons; Dr. D. K. Shute, Columbian University of Washington, D. C., alternate; Dr. Theo. M. Gill, Smithsonian Institution, Washington, D.C., was elected to the vacancy in the Executive Committee.

The following papers were read: "On the Identity of Structre of Protoplasm with that of Striped Muscle," by Dr. Carl Heitzmann, of New York City. "Some Problems Relating to Cerebral Fissures," Dr. Wilder, of Cornell University. "A Plea for a Methodcally Written Text-book on Anatomy," by Dr. Edmond Souchon, Tulane University, New Orleans. "Study of the Human Cranium," also "The Shortening of the Face-axis in the Evolution of the Mammalia," by Dr. Harrison Allen, University of Pennsylvania. "Methods of Estimating the height from parts of the Skeleton," by Dr. Dwight, Harvard University. "The Perineum and Perineal Body." Dr. Shute, of Columbian University, Washington, D. C. "The Study of the Muscular Tunic of the large and small Intestine of Man in the Region of Caecum," also, "A Note on the Occurrence of the Scapulo-Clavicular Muscle," by Mr. Moody. "Theoretical Anatomy of the Sympathetic System," Dr. Wm. Carr, Columbian University, Washington. "The Female External Genital Organs: a Criticism on Current Anatomical Description," Dr. Lamb, Army Medical Museum, Washington, D. C.

The following papers were read by titles in the absence of the authors: "In Our Two Years' Study of Anatomy: What partof the Subject should be covered in the First Year's Work, What part in the Second?" by Dr. A. D. Bevan, Rush Medical College. Two papers by Prof. P. A. Fish, Cornell University, namely: "The Form and Relations of the Nerve-Cells and Fibres in Desmognathus Fusca;" and "The Terminology of the Nerve-cell."

An abstract of these papers and the discussions will be published with the proceedings of the Association.

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D., AND SAMUEL M. WILSON, M. D.

THE NEW ORLEANS MEDICAL AND SURGICAL JOURNAL

contains an article by A. S. Wheeler, D. V. S., on

**Tuberculosis.**

In this the author states that tuberculosis may result in human beings from the use of either the milk or meat of infected animals, and that there are no "known creatures, inhabiting air, land, or water, which may not be the hosts" of this disease. He gives quite a list of birds and quadrupeds, which various observers have found infected, and states that with tubercle, as with anthrax bacilli, the earthworms may play a prominent part in bringing the dangerous organisms to the surface of a pasture, and he goes on to show that other cattle diseases are caused to spread through herds through the ministrations of parasites (the grub, the cattle tick, etc.)

Dropping speculation, statistics are quoted to show that very few calves are tuberculous at birth, but the percentage increases with their age, up to seven years or more, and still more significant is the fact that cows are more frequently affected than bulls and oxen, by an enormous ratio.

One great reason for this preponderance among cows is the habit of choosing a cow with a narrow chest and wide pelvis for breeding for milk; but another is the crowding of numbers of cows in a poorly-ventilated stable throughout the greater part of the year, to obtain milk for city consumption.

The author passes on to meat inspection, and speaks of the old church laws, and particularly the Jewish laws, which compelled the rejection of meat of unhealthy animals, and mentions the discovery he made in a slaughter-house, of a tuberculous liver, weighing fifty-one pounds, which had come from a dairy cow.

The article of Prof. Law is now partially quoted, showing the extreme probability of a constitutional disturbance from the absorption of toxins due to the presence of tubercle in an animal; but not necessarily depending on tubercle in the human being secondarily affected.

Koch's tuberculin, although perfectly sterilized, gives a decided reaction in any one who is already infected with tubercule, and greatly increases the destruction going on. While it has not yet been proved by Prof. Law that these toxins can originate tuberculosis in any one, it is evident that cooking the milk or meat is not sufficient to prevent a person, already slightly affected, having the reparative processes stopped and the destructive ones stimulated by the ingestion of these toxins.

The author closes with a plea for the systematic use of tuberculin as a scientific and absolutely sure test for tuberculosis in cattle, and for the destruction of those beasts reacting to it.

In the same number Dr. B. A. Pope reports a

**Case of Hysterical Alexia, Cured by Suggestion.**

The patient was a girl 13 years old, beginning to menstruate, and who had formerly been very bright, cheerful, etc. The child seemed dull, rather indifferent to her surroundings, and was very anæmic. She complained of almost constant headache and of inability to read or to sew.

There was inequality of pupils, and mild photophobia, and testing without glasses gave V-$\frac{20}{200}$ for each eye; but with the trial frame $\frac{20}{20}$ in each eye, and in both. On removal of the frame the former condition appeared.

Under atropine the vision was for each eye, H=0·50 D. Glasses were prescribed +0·25 D for each eye, and worn constantly, and as a result she reads well, does fancy work, and has improved in general condition.

The author thinks that this child had, through association with children who wore glasses, became convinced that glasses were necessary to good vision. He does not think this case resembles hysterical amblyopia; but is rather like some recent German cases which have usually occurred in boys and, being under the age of puberty, had no sexual cause.

Dr. Otto Lerch has an article on

**Geology and Medical Science.**

He regards a knowledge of geology a very important aid to a physician, particularly in ordering a change of climate; but, also in recognizing with more certainty symptoms complained of as due, in part at least to the climate, soil, and water of the place in which his patient lives, and to be remedied by removing him.

In regard to choosing another climate for an invalid—the mistake would not be made, by one thoroughly versed in the physical geography of the country, of sending a consumptive to the western prairies. These lands are elevated and dry; but, owing to their sudden blizzards, are subject to a change of temperature of possibly sixty degrees, the author states, in an hour.

Then also, a mineral spring may contain a very desirable water; but, if situated in an unsuitable region it would be folly to send a patient to it.

Dr. Henry Burchard read before the Philadelphia County Medical Society a paper on

**Gout and the Teeth.**

Trifacial neuralgia is more frequently due to irritation of the teeth than to any other cause, the author says, and numerous other disorders are more or less aggravated, and continued, by faulty teeth. Specialists in rhinology and ophthalmology recognize these facts, but general practitioners generally seem to ignore them.

The difference between diseases affecting the tooth pulp. and those limited to the pericementum was explained, and the different lines of treatment called for.

A disease known as pyorrhœa aveolaris, or phagadænic pericementitis, has attracted attention for years, and is the cause of the loss of as many or of more teeth than dental caries. It is a progressive destruction of the peuiosteum of the teeth, and this, and erosion of the teeth, the author thinks due to a gouty diathesis.

Dental erosion is a progressive loss of tooth substance by decalcification, a chemical solution of the lime salts, and not associated with caries. It is largely confined to those surfaces in contact with the labial and buccal mucous membranes.

"Phagedenic pericementitis is a degeneration of the retentive apparatus of the teeth, which arises without mechanical violence, specific virus, or the selective action of drugs, and proceeds to its termination with, or without, the formation of calcic deposits and true pus (although the pus and deposits are usual associates), the process terminating with the loss of the teeth." Men and women are both subject to this disorder, and although cases occur before thirty years of age, they are rare.

Two types of this affection, depending on the part of the membrane attacked, are known. The more common of these begins as a marginal disease, a deepening of color and a softening of gum at the tooth margin. This increases, and by the time it attracts attention a separation is beginning between tooth and gum. Pockets form, and in them are pus and concretions; these increase, and finally result in the casting of the teeth, as foreign bodies, and the processis usually ended. In contradistinction to salivary calculi, the concretions form beneath the gum, instead of on it.

In spite of local therapeusis, this disease recurs or persists, and for this reason a constitutional cause has been assigned to it.

In dental erosion we find, in situations where the lactic acid due to fermentative micro-organisms is in least amount, a progressive loss of enamel, and then of dentine. One or more grooves may be seen on the labial surface, the enamel destroyed in greater amount than the dentine—the reverse of caries.

In most of these cases a history of gout can be obtained, or, if not, the disease appears later.

The author goes on to describe gout in its better known phases, and to give its causation, pathology, etc., and then states that the most satisfactory treatment known at present seems to be by lithium, and particularly by lithium Rochelle salt, in which part of the sodium is replaced by lithium, and quotes Bartholow as saying that manganese is useful, both by relieving the disorder and by assisting in oxidation.

In the discussion which followed, it was stated that uric acid, urates of soda, etc., have usually been found in these concretions, when they have been analyzed.

Dr. S. Solis-Cohen showed a case of

**Acromegaly,**

which he had treated with thyroid powder, so far with benefit.

The patient, a man of about fifty-two years, had applied for treatment for excruciating headache, which prevented his lying down, and which was increased by pressure on the scalp.

Examination demonstrating symptoms of acromegaly, the patient was put on treatment of desiccated thyroid gland, and improved from it.

One of the symptoms was polyuria, and as thyroid powder usually increases the urine, it was thought strange that it lessened it in this case. The author thought this due to a lessening of the production of the toxins causing the symptom. Five grains of a powder prepared from desiccated sheeps' thyroid glands was given every morning.

Other papers in this issue are: "A Description of a Case oi Circumscribed Scleroderma or Morphœa," by Dr. George Kreegen, and a Clinical Lecture on "Hydrosalpinx and Pyosalpinx," by Dr. Angustin H. Goelet.

---

### Dyspepsia.

When accompanied by hyperacidity of the stomach, with pain or vertigo, Robin prescribes:—

℞

| | |
|---|---|
| Bitartrate of potassium | ʒiij. |
| Sublimed sulphur | ʒiss. |
| Prepared chalk | ʒss. |
| Dover's powder | gr. xv. |

M. and divide into 10 powders. One powder to be taken before each meal.

If the pains are severe:—

℞

| | |
|---|---|
| Hydrochl. of morphine, Hydrochl. of cocaine | āā gr. ½. |
| Lime-water | ʒij. |

M. Sig. Teaspoonful at a dose.

—*Le Prog. Med.*

---

### Diabetes Mellitus.

In order to relieve the dryness of mouth, which is often so troublesome, the nitrate of pilocarpine,—$\frac{1}{6}$ grain,—made up with a sufficient quantity of glycerin and gum to form a small pill, may often be used with advantage. From five to seven pills are taken during the day, being allowed to dissolve slowly in the mouth. It may be applied in solution, if preferred:—

℞

| | |
|---|---|
| Nitrate of pilocarpine | gr. ¼. |
| Alcohol of 40 degrees | mxc. |
| Distilled water | ʒij. |

M.

The tongue is moistened with five or six drops of this mixture, either pure or diluted with ½ drachm of water. The application may be repeated four or five times during the day.

---

### Vomiting.

*The American Doctor* says that oil of cloves in ½-to 1-drop doses, given in a suitable menstrum will control excessive vomiting.

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## MEDICINE.

### Tobacco Smoke: Its Action as a Microbicide.

What has the French Society of Hygiene to say against the abuse of tobacco? We see in the *Italia Terniale*, of February 21st, that after many experiments Prof. Tassinari is going to publish an interesting work, of which the following are the conclusions:

1. The smoke of the Cavour, Virginie and Toscan cigars and black and short cut tobacco possesses a very great bacteriological power, especially against the bacillus of Asiatic cholera.

2. This action as a microbicide seems to be, according to all probability, due to the empyreumatic products of the nicotine.

3. In cholera and typhus epidemics the use of tobacco may be useful rather than injurious.

4. Tobacco smoke deserves careful consideration in regard to the hygiene of the mouth, as a preventative of diseases.

In 1832, when the cholera epidemic spread through the Mediterranean and menaced Paris, we smoked our first cigar, without any enjoyment and with the inconvenience of a novice in smoking, because we were told that cigar smoke prevented cholera. To-day they say it destroys bacteria. That is all the difference.—DR. DE F., *Journal d' Hygiene.*

### The Therapeutics of Oxygen.

Dr. A. W. Catlin, of Brooklyn, states that the therapeutic use of oxygen is of very recent date. The treatment of disease by natural means is proving more and more efficacious as experience increases. Oxygen is a distinct remedial agent—one that should not be left untried until the patient is *in extremis*. It is the surest and most satisfactory stimulant that we possess, and is applicable to many conditions. In profound shock, from whatever cause, it has been found to exercise a reviving effect. It is taken up quickly by the blood, but its chief value is in its effect upon the nerve centers, upon which it exercises a quiet and soothing effect. In hemorrhage from typhoid fever he has seen relief in many cases. It would produce sleep, favor assimilation and shorten the period of convalescence. No agent is so well tolerated or so useful in restoring the equipoise of the physical condition. In cases of child-birth, pneumonia, bronchitis, and other exhausting diseases, the use of oxygen is indicated, and it should not be given late, but early.—*New York Medical Journal.*

### Physical Diagnosis of Biliary Calculi.

C. Gerhart calls attention to the early symptoms of biliary colic. The attack begins often four to five hours after a hearty meal, or when the food passes into the duodenum, causing, by a reflex action, an expulsion of bile from the gall bladder. This will produce a temporary sensible enlargement of the sac (supposing that obstruction of the duct exists, and the gall cyst retains its distensibility). This enlargement subsides as soon as the stone has passed; the localized inflammation having produced some peritonitis, a circumscribed area of crepitant rales can be heard with the aid of the stethoscope. This, together with pain, may exist some little time after the stone has found its way into the intestine. This latter condition is often greatly ameliorated by applications of ice water. An extension of the peritoneal inflammation to the pleura is but rarely observed. As a most frequent complication, we have an appendicitis due to a mechanical or chronic obstruction. If the attack is prolonged, the liver becomes enlarged, and its edges can be easily palpated, and often seen, if the patient is emaciated. Transient enlargement of the liver, one of the important symptoms, is also met with in cholelithiasis, or when the ductus communis is obstructed by ascaris lumbricoides, or other catarrhal inflammatory exudations. The head of the pancreas is also the seat of a new growth or swelling, thus producing mechanical pressure upon the duct; on the other hand, it is absent in cardalgia or purely nervous hepatic colics.

Cholelithiasis can be excluded if there be an absence of crepitation over the seat of the gall cyst—if there is no enlargement of the same, and if after several attacks there have been no calculi found in the fæces.—*Deut. Med. Wochen.*

### Salicylate of Sodium in Cancer.

In a case where the bone had become involved, secondary to cancer of the breast, Aikmann obtained decided relief of pain by the administration of salicylate of sodium in doses of 10 grains three times a day. Large doses of opium had been given in vain.—*Glasgow Medical Journal.*

### The Ice Bag.

There are probably few persons who are acquainted with the great value of the ice bag, especially in the treatment of acute inflammatory conditions. It is useful in the early stages of all acute inflammations, such as pneumonia, pleurisy, peritonitis, pelvic cellulitis, erysipelas, etc. It must be remembered that the ice bag should be used only in the first stages of the disease. At this period it checks the growth of the microbe upon which the inflammation depends; and, by lessening the blood-supply, prevents in a large measure the exudation and other mischievous processes which accompany acute inflammation. The ice bag may well replace, in the early stages of inflammation, the time-honored

poultice, which is at best an unclean remedy, possessing no other virtue than that of moisture and warmth.

It is important to remember that cold has a depressing effect; hence the application of the ice bag should be carefully watched. Except when the application is made to the abdomen or very fleshy parts of the body, one or two thicknesses of flannel should intervene between the bag and the skin, so as to prevent chilling to such a degree as to produce sloughing. It is also well to remove the bag every two or three hours, and apply a fomentation for fifteen or twenty minutes.

In most acute inflammations, the application of the ice bag must be limited to the first twenty-four or thirty-six hours; at the end of which time, and sometimes before, the ice bag should be replaced by cloths wrung out of cold water, and the application of heat should be very frequent, say every two or three hours. After two or three days, continuous warm applications should be used in place of the ice bag.—*Modern Medicine.*

### Pleurisy.

℞ Guaiacol pure..... 5j.
Tinct. iodine..... 3vij.

Paint the whole of this liquid each evening on the affected side. The temperature quickly falls, an abundant perspiration takes place, and the effusion soon becomes absorbed.—*Prescription.*

### Coffee versus Digestion.

Prof. Schutz-Schutzenstein, an eminent German scientist, has recently completed some interesting experiments in relation to the effect of tea and coffee on gastric digestion. He found that an artificial gastric juice was able, in eight hours, to digest ninety-four per cent. of coagulated egg albumen. When tea was added, other conditions remaining the same, only about sixty-six per cent., or two-thirds as much, of the albumen was digested; and when a decoction of coffee was mixed with the digesting albumen, only sixty-one per cent., or less than two-thirds, of the albumen was digested. The result was believed by the Professor to be due to the influence of the tannin upon the albumen. The effect was found to be less in proportion as the infusion of coffee or tea was weaker, and the conclusion was expressed by the experimenter that the deleterious influence of these common beverages is due not to the thein and caffein which they contain, but to the constituent tannin, the suggestion being made that an infusion made by pouring boiling water upon the tea or coffee and allowing it to stand for a few moments, instead of boiling for some time, is less deleterious in consequencee of the extraction of a smaller quantity of tannin.

This conclusion is doubtless correct, but it is equally true that an infusion thus made contains a smaller amount of thein and caffein. These substances are less easily soluble in water than tannin, and consequently the less injurious effect of the lighter infusions is not due to the fact that they contain less tannin, but that they contain less of all the poisonous properties contained in the tea leaf and the coffee berry.—*Modern Medicine.*

### Pyoktanin in Diphtheria.

Horing (*Memorabilien*) refers to the treatment he adopted early last year in twenty-seven cases of diphtheria, the results of which were published in the *Aerztl. Memorabilien*, vi. and ix., 1892. Since then, Horing has continued to use pyoktanin, and claims excellent results. The practice was to apply a 3 per cent. solution two or three times daily to the pharynx and downwards to the epiglottis, the retention of the liquid in young children being secured by immediately placing their heads low, thus aiding the swallowing of the liquid. Otherwise the drug was not administered internally, nor was it directly introduced into the affected tonsil. Simultaneously the patients are syringed with lime water, or are allowed to use it as a gargle or inhalation, while salicylate of soda is given internally.

When the nose is affected, a tampon soaked with the solution is retained in the cavity, and in milder cases the application of pyoktanin to the pharynx, etc., is the only treatment followed. In support of his practice, Horing says he has found even a 1 in 1,000 solution to destroy the Klebs-Loeffler bacillus, as also the more active streptococcus, the latter in the course of half a minute. In practice, the local effects are antiseptic, healing and destructive to the false membrane, the general results being diminution of pain and pyrexia without the production of toxic symptoms. The present cases enumerated are 112, two of which succumbed for reasons explained; the remaining 110 cured cases included many serious cases which had been despaired of. The symptoms, spread of contagion, and sequelæ, are quoted in support of the diagnosis. The author, in view of his experience, supported by that of others, regards pyoktanin as a specific against diphtheria.

### Treatment of Biliary Lithiasis.

In cases of acute hepatic colic, Grasset advises:

1. Place the patient in a full, warm bath, where he should remain from three-quarters to one and a half hours.

2. Give every hour, or even every half hour, a teaspoonful of:

℞ Sat. chloroform aq..... 150 grms.
Dill. water..... 100 "
Syr. orange..... 50 "

Or, chloroform may be inhaled and morphia given subcutaneously.

If olive oil is tolerated, 200 cc. may be given in wineglassful doses every quarter hour.

The food should be cold soup or milk, or ice cream. Injections to produce liquid stools should also be used.—*Times and Register.*

### Treatment of Chronic Gastric Ulcer.

Stepp (*Therap. Monatsh.*) describes a method which he has successfully followed during the last four years, the object of which has been to prevent fermentative changes in the organ with their damaging influence on the gastric walls, and, further, to exert a beneficial and tonic action on the damaged surface. This he has effected by the frequent use of a ¼ per cent. aqueous solution of chloroform, with the addition of subnitrate of bismuth, the latter, however, being of secondary importance. The water is given in quantities of one to two bottles daily. The author says chloroform has no anodyne or narcotic properties when administered internally, its effects being more those of an astringent, a tonic, and an antiseptic. A few cases are recorded showing how early the patients became convalescent under this treatment. When vomiting or hematemesis complicated the affection, the author found the chloroform acted effectually in quenching thirst, and arrested nausea and hæmorrhage. A burning sensation, probably at the seat of the ulcer, is always produced at first, but disappears completely in eight to ten days. No unpleasant consequences occurred, but indirectly a clean tongue and improved appetite seemed to be produced. At the end of the second week beef-tea could be administered, during the third eggs, and afterwards selected meats could generally be added to the preceding foods.

### Notes on the Physiological Action of Ozone Preparations

Dr. W. G. Thompson draws the following conclusions respecting the effect of ozonizing agents when given by the stomach or injected directly into the intestines or the blood. The experiments were made on dogs.

1. When injected in the circulation in full strength, *i. e.*, fifteen volumes per cent., they have a very destructive action upon the blood, ultimately having the effect of reducing rather than of oxydizing agents for the tissues.

2. Acting through the stomach or intestines, they may similarly affect the blood, and in addition they destroy the gastric and intestinal mucous membrane.

3. Given in medical doses by the stomach, their only benefit, if any, consists purely in their local action in the alimentary canal, in possibly preventing abnormal fermentations.

4. If so used, care should be exercised, owing to the great variability in strength of different preparations.

5. Ozone is of no real value to the tissues, whether inhaled or drunk in fluid preparations, and it may be exceedingly harmful.

### Simple Cure for Hiccoughs.

"I was just about to send a cure for hiccoughs to the New York man whose case has been puzzling the doctors, when I read that he had been cured by laughing heartily at a colored man's description of what seemed to the patient a most ridiculous cure," said a Pittsburg physician. "You hear of numerous cures for hiccoughs, such as holding your fingers in your ears and having some one give you a drink of water, holding one's breath for a period, etc.; but I doubt if any will stand the test as well as a practical cure, which for twenty years has never failed me once in all the hundreds of cases I have tried it. It may seem just as ridiculous as the cure proposed by the colored man in New York—so ridiculous that many will not think it worth while to try; it is nevertheless a sure cure:

"All you have to do is to lie down; stretch your head back as far as possible; open your mouth widely; then hold two fingers above the head, well back, so that you have to strain the eyes to see them; gaze intently upon them and take long, full breaths. In a short time you will be relieved of that troublesome hiccough.

"Now I have tried that sure cure on all sorts of cases, from the simple form to the chronic, and it works well with all. I remember it was given to a man on the way to New York to consult a specialist on his case—one of six months' standing—and it cured him in a few minutes. He turned around and said: 'What do you charge for that?' 'Nothing,' was the reply, 'except that you publish it to sufferers.'"—*Charlotte Med. Journal.*

### Protoplasm up to Date.

Protoplasm was formerly described as a homogeneous structureless jelly, but it is now clearly proved to be of various kinds, differing in each organism, and in different animals. It is of very complicated formation; a more or less delicate network of interwoven fibers forming the basis, and a clear watery fluid permeating its meshes, to soften its solidity. These fibres are strung with infinitesimal granules, which move to and fro along their length, aad their activity seems to be perpetual. They are apparently without structure, but they are supposed to vary in their composition, and to be capable of even minute subdivision.

Protoplasm cells contain, besides the clear protoplasm, a nucleus (which again contains minute fibres, fluids and granules), and also a compound called nuclein, in the form of dots, granules or rods, variously arranged, and it is frequently found enclosed in a tubula. This nuclein contains all the properties of the whole protoplasm, and in many instances all the essential characters of the animal or plant to which the particular cell belongs, and probably all the hereditary characters which the plant may transmit to its offspring.—*Times and Register.*

### On the use of Bromide of Potassium and Salicylate of Sodium in Headache.

Dr. Brunton, in *Practitioner*, first alludes to the fact that absorption from the stomach frequently ceases entirely during a headache, and drugs given by the mouth have then no effect. The only treatment in such cases is

morphine, hypodermically; but the possibility of establishing the morphine habit must be kept in mind.

He estimates that 80 to 90 per cent. of all headaches are due to defects of vision, uncorrected hypermetropia, myopia, astigmatism, inequality of the focal distance of the two eyes, and imperfect convergent power; 10 per cent to decayed teeth; and about 5 per cent. to disorders of the nose, throat, ears, scalp, and other causes. Headache due to visual defects is generally frontal, temporal, or occipital; but in one case recorded in the paper it was about 2½ inches below, and one inch to the right of, the occipital protuberance. In those cases associated with unequal visual power of the two eyes, it frequently affects the side of the weaker one.

A very common form of headache begins with unwonted irritability at night, which, however, is not always present. The patient wakes at four, five, or six o'clock in the morning, but feels disinclined to move, turns over, and goes to sleep again. He again wakes at seven or eight o'clock, with a distinct, but not severe headache, which increases as the day goes on, becoming very severe in the evening, and culminating in vomiting, which is followed by relief. If, however, he gets up when first waking, he generally escapes. These headaches may frequently be prevented by taking pot. brom. grs. $\frac{30}{3}$, with sodii salicyl. grs. $\frac{10}{3}$, in a tumblerful of water, when the feeling of irritability appears in the evening, or, in the absence of that, when waking early in the morning; and this may be repeated once or twice.

The two drugs combined act much better than either of them separately.

Dr. Brunton concludes his paper by contrasting our present armament of treatment of headache with that of twenty years ago; for whereas then we had slight power over them, now we are able to cure or relieve nine out of ten cases by attention to the eyes and teeth, and the use of bromides, salicylates, antipyrin, phenacetin, exalgine, and other remedies synthetically produced.—Robert E. Lord in *Manchester Med. Chron.*

### The Antitoxic Function of the Liver.

Professor Bouchard attaches great importance to the power of the liver cells to nullify the effects of the toxines manufactured in the intestines. The correctness of this has been corroborated by the experiments of Schiff, Heger, Roger, and others, who found that alkaloids injected into the branches of the portal vein were much less poisonous than when they were introduced into the general venous circulation. M. Pavlow has confirmed these results by a series of experiments of which I give a *resume.* If by means of a ligature placed on the portal vein, the blood is compelled to deviate from the liver and pass directly into the general circulation, poisonous symptoms appear, consisting of fever and nephritis with albuminuria. That this nephritis is not due to hypertension of the blood in the renal vessels is proved by the fact that no such kidney trouble is caused by the ligature of the inferior vena cave, although this manœuvre is productive of a greater tension in the renal vessels than the operation in question. A wound artificially produced in an animal whose portal vein has been tied heals very slowly, whereas a similar wound in an animal where the inferior vena cava has been ligatured cicatrises without difficulty. The conclusion is that when the blood is prevented from passing through the liver toxæmia occurs, which is solely due to the fact that the liver no longer plays a protective role against toxtines which are being continually fabricated in the alimentary canal.—*Medical Bulletin.*

### The Diagnosis and Prophylaxis of Intracranial Complications from Ear Disease.

By P. M'Bride, M. D.—This is an interesting contribution to the literature of the intracranial affections which may follow disease of the ear. Those which he specially considers are (1) meningitis, (2) phlebitis of the cerebral sinuses, and (3) abscess. In dealing with the symptoms manifested by such patients, the first point to be attended to is to have a careful objective examination of the ear made. If a patient suffers from chronic suppuration of the middle ear, and at the same time shows evidence of intra-cranial inflammation, probability points to the former being the cause of the latter, and presumptive evidence of the connection of the two, as cause and effect, is afforded, if the history points to pain localized in the ear as having preceded more diffused headache. The common belief that perforation of Shrapnell's membrane more frequently leads to intra-cranial complications is not shared by him. In estimating the probability or the reverse of the extension of inflammation from the ear to the endo-cranium, much importance is attached to the presence or absence of fetor. The first manifestation of danger is almost invariably pain in the ear or over the mastoid, the latter, indicating the spread of the inflammation in an outward direction, being favorable in character. Pain in the ear is soon followed by diffuse headache, and vomiting may or may not occur. The preparation of an hourly temperature-chart is recommended, and if marked fluctuations within short periods, if rigors be severe and frequent, and associated with perspirations, septic thrombosis, usually involving the sigmoid sinus, may be suspected.

In cases of intra-cranial abscess, Dr. M'Bride depends, for purposes of differentiation, on pulse, temperature, and percussion tenderness, the two former being of the most importance. But, when all has been said, the diagnosis of intra-cranial abscess can rarely be arrived at with any degree of certainty.

In considering the question of prophylaxis, excision of the tympanic membrane and malleus, with or without removal of the

incus, opening of the mastoid antrum and Stacke's operation are specially discussed, and the difficulty of the question of when to recommend an operation is carefully considered.—*Edinburgh Medical Journal.*

### External Periostitis Suppurative following Acute Attical Inflammation.

The child, five years old, had had measles three weeks before onset of pain in the ear. On examination of the tympanitic membrane, the membrana flaccida was found to be deeply injected. Under treatment, the pain abated; but within ten days the cheek and front of the ear swelled, which, on examination was found to be due to an external periostitis near the junction of the bony and cartilaginous canal. The abscess which formed was opened in front of the tragus, the cavity washed out, and a portion of necrosed bone removed.—*Archives of Pediatrics.*

### Poisoning from Veal.

A German ppysician, Dr. Van Ermengen, recently investigated the cauie of an outbreak of gastro-intestinal inflammation involving fifty-six person, four of whom died. The suspected cause was the flesh of two calves. On investigation it was found that the calves, when killed, were afflicted with a sickness of some sort. Examination of a portion of the body of one of these animals, and of the liver, spleen, and intestines of one of the victims of the poisoning, revealed a germ closely resembling those known to be the cause of hog cholera.

### Leprosy not Hereditary.

The rapid development of this disease in the Sandwich Islands and in India, and the death of Father Damien, resulted in the establishment, by the English Government, of a Leprosy Commission to investigate this disease. They found that the first case of leprosy in the Sandwich Islands occurred in 1830,—sixty-four years ago,—since which time it has increased until at the present time there is one leper to every thirty healthy persons in the Sandwich Islands. There are at the present time more than 1000 lepers at the Leper Asylum on the island of Molokai. In India there is one leper to every 2000 persons. By careful inquiry, the Commission learned that of healthy persons who associated closely with lepers, eating and drinking with them, 700 in 10,000 became lepers. Even the earth trodden by lepers is found to contain the germs of this disease.

The Commission concludes that leprosy is not hereditary. They bslieve that the soil and air of India have become so charged with the germs of this disease that any person who is susceptible to it is likely to come in contact with it somewhere, at some time, and become infected by it.

Recent investigations seem to show a possible relation between this disease and tuberculosis, or what is commonly known as consumption. The germs of the two diseases are so nearly alike that it requires an expert to distinguish them; they do not differ more than do the germs of leprosy obtained from different localities.

### Diagnosis of Diphtheria.

Dr. Wethered recently reported to the London Medical Society the results of a study of twenty-six cases of diphtheria and sixteen of follicular tonsilites. The study was made by means of bacteriological cultures upon glycerine agar-agar in large test-tubes. The test-tubes were then placed in an incubator at a temperature of 73° C. for twenty-four hours, when the cultures were examined microscopically. In the sixteen cases of follicular tonsilitis, staphylococcus only was found. In the twenty-six cases of diphtheria the Lœffler bacillus was found in fifteen cases, streptococcus in three cases, and staphylococcus in eight cases.

### A New Role for Bacteria.

M. Tischutkin maintains that the so-called carnivorous plants are incapable of digesting albumen; but that their sole characteristic property resides in their ability to absorb albumen which has been digested by bacteria. These are the conclusions which he draws from a careful study of the subject:

"1. The disintegration of albuminous compounds by the secretions of carnivorous plants is due to the growth of micro-organisms, principally bacteria.

"2. Micro-organisms possessing the power of dissolving albuminous compounds always vegetate in the secretions of completely developed carnivorous plants.

"3. The disintegration of the albumen does not commence at the moment of the secretion of the fluid, but only after micro-organisms have developed in sufficient numbers in the secretion.

"4. The micro-organisms found on the leaves of carnivorous plants come principally from the air, though they may be derived from other sources.

"5. The name 'carnivorous' plants is to be understood in the sense that the plants only assimilate the products which the lower organisms have set free.

"6. The role of the plant itself is only to furnish a medium in which certain organisms may live and develop."

### The Problem of the Etiology of Menstruation.

There is an activity of interest now manifest in the perplexing problem of the etiology of menstruation. One of the most interesting papers presented to the profession within the year, was read before the British Gynecological Society by Christopher Martin, M. B. Edin., F.R.C.S. Eng., Surgeon to the Birmingham and Midland Hospital for Women. His title was "The Nerve Theory of Menstruation." We have not space to follow his very

interesting reasoning nor the process by which he arrives at his conclusions, but his opinion is as follows: "The position of the menstrual centre can at present, only be surmized, but there is reason to believe that it will probably be found in the lumbar enlargement of the spinal chord. This portion of the chord is intimately associated with all the pelvic functions. It has been proved to contain, in the human being, the centres (*a*) for micturition, (*b*) for defecation, ond (*c*) for erection and ejaculation. Experiments on animals have demonstrated that it contains a center governing the act of parturition. . . . And if the parturition center be found there, the menstrual center will be not far away. The center is certainly not in the pelvis. There are ganglia in the substance of the uterus, ganglia in the nerve plexuses at the side of the uterus between the layers of the broad ligament, and on the cervix is situated a large ganglionic mass, developed in connection with the utero-vaginal plexus, called the "ganglion cervicale uteri." If these ganglia have anything at all to do with menstruation, they are certainly controlled by a higher center.

### The La Borde Method.

Professor Coutenot (Besancon) was recently lecturing to his students on asphyxia, and, as a young girl had just died in the hospital from tubercular meningitis, the idea struck him to go to the corpse and give a practical lesson on the new method of treatment by traction of the tongue. What was his astonishment, as well as that of his assistants, when, after a few minutes, he saw the respiration returning, the heart beating, and the face becoming colored.

This phenomenon lasted three-quarters of an hour. Death really existed, but the reflex action of the bulb—a respiratory centre—had not totally disappeared, and the traction had stimulated the phrenic nerve to bring the diaphragm into temporary action.

Failure of this resuscitating method would appear to afford an indubitable test of death. —*Times and Register.*

### Recurrent Tonsillitis.

Dr. G. A. Leland, in the *Boston Med. and Surg. Journal*, describes a method of dealing with tonsils in recurrent tonsilitis. He divides the tissues between the crypts by knife, scissors, and hooks, removing the tabs of tissues, and painting the surface with iodine and glycerine (Mandl.) This operation is frequently repeated, and in the author's hands, is uniformly successful; it is especially of service when tonsilotomy is objected to. He describes two somewhat scythe-shaped knives, which are introduced at one and brought out at another crypt, cutting the tissues between. —*Ex.*

## SURGERY.

### A Case of Primary Tuberculosis of the Mastoid Process.

Dr. Herman Knapp, of New York, describes the case of a child, aged five, whose right mastoid and supra-auricular portion of the temporal bone were swollen, ulcerated, granulating, and discharging fœtid matter. Both auricles, meati, tympanic membranes and tympani were perfectly normal, as far as could be discovered by physical examination, and the hearing in both ears was unimpaired. This affection of the mastoid was only a part of a widespread bone-affection, as the child had a granulating ulcer around the left ankle and necrosed bone around both orbits.—*Archives of Otology.*

## OBSTETRICS.

### The Treatment of Uterine Inertia Without Drugs or Tonics.

Van Waters (*New York Medicat Journal*, June 24, 1893,) remarks that the beneficial action of a suppository in the rectum in constipation is widely known. He asks: Why should not the same good result follow the use of a suppository in uterine inertia, and what more ready and effective suppository could we have than the hand? Hence, when the case has so far progressed that we are satisfied it is time for delivery to take place and yet inertia has supervened, the hands should be rendered strongly aseptic by the use of water, soap and a brush, and afterward immersion in a creolin solution. Then, after the administration of a little chloroform, the hand, well annointed with vaseline, should be gradually and slowly introduced into the vagina. As soon as it has remained there a few minutes pains will commence and increase in severity, in some cases to such an extent that the hand has to be withdrawn. In those cases in which Van Wates has resorted to this procedure the results have been most gratifying.—*The University Medical Magazine.*

## ORIGINAL ARTICLES.

### RACHIOTOMY FOR SPINAL INJURY: WITH REPORT OF CASE.*

J. C. OLIVER, M. D., Cincinnati, Ohio.

The number of cases of this sort in which operative interference has been practiced is so small that it seems the duty of each operator to put on record the report of all cases occurring in his practice. Each additional case must prove of value in determination of the proper procedure to be adopted in cases in which there are symptoms referable to injury of the spinal cord.

The report here presented, while it does not contain anything new or extraordinary, serves to emphasize facts reported by other observers.

Chas. M., æt. 34, American, farmer, was first seen by me Sept. 19, 1893. Fourteen monthe ago the patient fell from a tree, a distance of about twenty feet. He struck between his shoulders, head foremost; the body then twisted violently toward the right side. The patient was, so to speak, jack-knifed.

Consciousness was not lost, but an immediate paraplegia supervened. Within two days a bed-sore appeared over the sacrum, which persisted for eight months. The paralysis involved both the bladder and rectum; the urine dribbling away constantly.

The pain and soreness from the immediate injury gradually passed away, leaving behind the paraplegia, incontinence of urine and rectal incapacity.

At the time of my first examination, the conditions above mentioned were found. There was total and absolute loss of sensation and motion of the lower extremeties, a constant dribbling of urine and rectal apathy. A projection over the region of the eighth and ninth dorsal vertebræ was readily apparent. The reflexes were all present and exaggerated. The legs were not atrophied or contracted. No reaction to either faradic or galvanic current.

The general condition was excellent, he being well nourished and of good color. He was able by means of a bar to raise himself from his bed into a rolling chair, and then to propel himself with ease. The girdle sensation was not well defined, although there was the suggestion of one present.

Aftor consultation with Drs. Comegys, Conner, Dandridge and Freeman, the patient was advised to have the parts thoroughly explored in order to ascertain the pathological condition present. At the same time, he was informed that the strong probabilities were against his receiving any benefit from the operation.

The patient readily consented to the proposed operation, so on September 28, with the assistance of Drs. Freeman, Mussey, MacMillan and Garmuly, and in the presence of Drs. Comegys, E. W. Mitchell, B. Stanton, F. W. Langdon, Geo. E. Jones, N. P. Dandridge, P. S. Conner and others. The operation was made at Christ's Hospital. After cutting through the skin and clearing the muscles from off the laminæ, the spinous processes

* A paper read before the Ohio State Medical Society, Zanesville, May 16, 1894.

were bitten off, a chisel was then used to effect an entrance into the spinal canal: this having been accomplished the arches were bitten away with a rongeur forceps. The arches of the seventh, eighth and ninth dorsal vertebræ were removed, and it was found that the seventh had been dislocated, being turned to the right, the eighth and ninth had probably been fractured, and the spinal cord had been caught between the dislocated seventh and the fractured eighth, thus producing an apparent disorganization of the cord for the space of about one-half inch. The dura mater was everywhere adherent to the bony canal. After these adhesions were separated, the dura was opened, and the cord found to be in apparently good condition above and below the pinched portion, but the structures of the cord seemed to be entirely absent from the pinched portiou described above. The portion under observation did not pulsate either before or after the operation. But a very small amount of fluid escaped when the dura was opened. The edges of the dura were not stitched together, but the muscles were sutered, anp then a separate (continuous) suture was used to draw the edges of the skin together. The usual dressings (dry) were then applied, and the patient returned to bed.

During the remainder of this day and most of the next the patient vomited excessively, apparently the effect of the ether. After this passed off, there was no unpleasant symptom.

The next day, (September 29), he complained of a drawing or constricting sensation in the hips. The urine was withdrawn by catheter every four hours.

October 6. Stitches removed. Union perfect.

October 16. At this date the patient's condition is very similar to that before the operation, except that he retains his urine for four hours without any passing away in the meantime, and the bowels move more easily than previously. He is now taking strychnia gr. $\frac{1}{30}$ three times daily, and is having daily massage for the legs and abdomen.

On November 3, he returned to his home. The paraplegia remained unchanged, the urine had become uncertain, sometimes being retained for four or five hours, and then again leakage would occur within a short time after the catheter was used. The bowels, he declares, move more easily and satisfactorily than at any time since the accident.

After this recital of the case it seems scarcely necessary for me to call your attention to the fact that the operation in this case was not productive of a cure, but I do wish to call your attention to the fact that a real benefit did occur in the urinary and rectal symptoms. This same fact has been noted by other observers, and as these are the symptoms which are most annoying to the patient, it seems to me that this improvement alone would suffice to recommend the operation.

I shall not inflict upon you a critical review of all the cases published under this head, but there are some points of exceedingly great interest which can only be brought out by comparison with other reported cases.

The question of the propriety of surgical interference in these (traumatic) cases is not at all a decided point. A second question, and to my mind an exceedingly important one, is *when* to operate after injury to the spinal column producing paraplegia.

In regard to the wisdom of operating in these cases there can be but one logical conclusion, *i. e.*, when other means have failed and the patient's general condition is such as to give one a reasonable assurance that the operation of itself will not prove fatal, then we should feel justified in resorting to active surgical intervention. From the literature at my command, and I have gone over this pretty thoroughly, one can not expect to accomplish much by operation; yet, from the fact that some few cases have been benefitted and because we cannot definitely tell the exact condition present in a given case, one should certainly make the exploratory operation and thus be convinced of the necessity or futility of further procedure.

When should the operation be made? At first blush it would seem probable that the proper time for interference would be as soon after the accident as possible, but experience has, I think, demonstrated the wisdom of postponing surgical intervention for a greater or less time according to the indications in particular cases. When paraplegia is an immediate consequence of the injury, it is probable that the damage done to the nervous elements

of the spinal cord is so great as to produce disorganization of that structure, and hence no operative measures will be successful in restoring lost function. It is true that the paralysis may be the result of pressure from a displaced fragment of bone, probably a small piece driven into the substance of the organ, but the strong probability is that we have to deal with a badly bruised or disorganized cord. For the former condition, rest and extension, or fixation, will accomplish all that rachiotomy can; for the latter nothing can be done.

Our colleague, Dr. Ryan, has reported an exceedingly interesting and suggestive case, illustrating the truth of the remarks relative to the method of treatment by rest, or at least by non-interference. This case is reported in the Lancet-Clinic for May 23, 1892, and briefly is as follows: A man fell from a telegraph pole and sustained a fracture of the dorso-lumbar spine. He had complete paraplegia, with the exception of some control over the extensors of the right toes. Retention of urine, constipation and atrophied limbs completed the clinical picture when he was brought to the hospital thirty-six days after the accident. He was treated with potassium iodide in large doses, the Paquelin cautery and extension in a plaster jacket. Recovery was complete.

Several important points are not stated in the report of this case, and the omission is undoubtedly due to the fact that the patient was not brought under Dr. Ryan's observation until thirty-six days after the receipt of the injury. The time of the supervention of the paraplegia is an important item bearing upon the nature of the spinal lesion. The result of the treatment in this case leads one to the conclusion that there was no organic lesion of the cord; the cause of the paraplegia was probably compression exercised by a blood-clot, which was subsequently absorbed.

An extensive quotation of cases is hardly necessary for the purposes of this paper, but a few in which operative measures gave relief would be appropriate in order to establish the line between operable and inoperable cases.

Rieder reports the case of a man who fell from a second story. Somnolence, paraplegia and anæsthesia of the lower limbs were present. The spines of the fifth and sixth dorsal vertebræ were prominent. Sixteen hours after the accident resection of the spines and laminæ was performed and the pressure upon the cord was relieved. Even at this early period the cord was somewhat softened. Six months afterward the patient had a slow, spastic gait, although the other symptoms were absent.

Weiss operated upon a man of 34, who had a dorse-lumbar kyphosis, the result of a fall; associated with this was paraplegia, paralysis of rectum and bladder. A month after the accident the arches were removed; the cord was bent; the dura was not distended and was left unopened. Immediate and permanent relief was experienced. The man returned to perfect health.

The quoted cases along with the one reported this evening, will, I think, suffice to call attention to the fact that the main importance of spinal fracture is, like fracture of the skull, the injury done to the nervous structures enclosed. Mere fracture of the spine is, of itself, no more important than fractures elsewhere. Injury of the spinal cord, providing there be more or less disorganization of the structure, is irreparable. August Weissman says, that, "nervous tissue once destroyed is never replaced," and the experience of physicians gives strong confirmation to this statement.

From these statements it is easy for us to arrive at the conclusion that surgical intervention in this class of cases can only be of avail when the spinal cord is structurally intact. The only difficulty in the way of giving us an absolute rule in these cases lies in the fact that our powers of diagnosis are not complete and perfect enough to positively state whether the cord is intact or not. Were it possible so to determine, a considerable amount of useless surgery might be avoided. As it is, we ought in every case, after the possibility of spontaneous restoration has vanished, give the patient the benefit of the doubt and accurately determine the condition of the cord.

Leaving out of consideration the above mentioned class, we still have a considerable proportion of cases in which compression is the condition present. This pressure may be caused in a variety of ways It may be due to hemorrhage, it may be bony, or it may be due to adhesions.

Theoretically it seems easy to diagnosticate hemorrhage; here we should have a gradually developing paralysis, it should not occur instantaneously; but an element of confusion arises from the fact that the patient may be so stunned by the fall as to be unable to say just when the paraplegia developed.

It seems to me impossible, with our present knowledge, to discriminate between bony compression and organic lesion of the cord. Undoubtedly the vast majority of actual nerve-lesions are the result of injury inflicted by the bony structures, yet it is undoubtedly possible (and reported cases prove their existence) to conceive of an injury sufficient to cause loss of function and not sufficient to interfere with the integrity of the cord.

For these compression cases rachiotomy should furnish relief, provided the compression has not been maintained so long as to cause actual degeneration of the cord. You will recollect that in the case reported by Rider, softening had occurred at the end of sixteen hours, and from the report we are led to infer that the spastic gait, from which the patient subsequently suffered, was the result of this softening.

Having, theoretically at least, divided these cases into the classes of operable and inoperable, the next, and most important, question is as to the time for operation. Should these operations be done as soon after the injury as possible, or are the best interests of the patients served by postponing operation until nature has been given a chance to repair the damage?

Rider's case would seem to prove that an acute, irreparable softening of the cord may take place within a few hours after the infliction of the trauma, while that of Weiss clearly proves that the cord may completely regain its functions even though subjected to pressure for a considerable period of time (one month). It is clearly evident that the variety and nature of the pressure is important. A pressure which interferes with the nutrition of the cord sufficiently to cut off the blood supply to a portion should be relieved at the earliest possible moment, lest the secondary condition be far more serious than the primary. Late removal of such pressure would be useless.

Compression from blood clots might be avoided by an early operation, or at least such compression could be much more quickly removed by the surgeon than when the process is left to nature. It seems to me that early operation is advisable in cases where there is the history of a slowly developing and gradually increasing paralysis. By means of an early operation all hemorrhage may be checked and the danger of compression from this source be reduced to a minimum.

A third advantage in immediate interference lies in the positive knowledge that would be obtained as to the exact condition present, and the prognosis could be much more intelligent. This point in certain cases is one of the very greatest importance to the patient and his family.

Prolonged compression could be obviated in every case by prompt operation and the danger from this source be avoided. Reported cases up to the present time are not very numerous, but those I have examined are not at all encouraging where the operation is undertaken at a late date.

On the other hand there are several valid objections which can be urged against early operation. In the first place a large percentage, (just how large I am unable to ascertain) of these cases die within the first few days following the injury, and were these cases operated upon the mortality following surgical interference would be very great, and the operation would have to bear the responsibility.

A second objection is the presence of shock, and shock is generally pretty pronounced in these cases. The additional shock of the operation might throw the balance against some patients who might otherwise survive the primary effects of the trauma. It seems to me that this same argument might be applied with equal force to any traumatism in which shock is a feature. This condition should be viewed in the same light in relation to rachiotomy as it is in regard to other traumatism. A danger in early operations, which would have had much more influence a few years since than it should have at the present time, is the danger of sepsis arising from the mushy condition of the parts, and also because of the anatomical arrangement of the structures invaded. This is a danger not to be treated lightly, but I feel that proper aseptic precautions will here, as elsewhere, prevent the introduction of septic matter; hence this danger, of itself, should not be

regarded as any contra-indication to the early operation.

The inability to clearly distinguish structures at an early period because of the conditlon of the parts is a more serious objection. The muscles and tissues will generally be found infiltrated with blood and more or less confusion from that source necessarily arises, but it seems to me the difficulties would not be insuperable: care and prudence would be required, but these every surgeon gives freely in every case.

It seems to me that it is perfectly legitimate to compare fractures of the spine with fractures of the skull; the conditions are very similar aud the dangers very nearly the same. In each case the gravity of the case depends upon the the injury to the contained organs, the fracture itself being of but little moment. What one of us would think of waiting to see whether a paralysis caused by a depressed fracture of the skull would disappear without surgical aid? What would be worse surgery than to allow the delicate nervous structure to be irritated and perhaps ruined by a pressure we could remove? And yet, if my comparison is a legitimate one, and I think it is, the same reasoning should apply to the spinal cord as is applied to the brain. It should be our aim and object to remove pressure from the spinal cord just as soon as possible after the infliction of the injury. Moullin advises early operation in those cases in which the spine is fractured by direct violence, and reserve late operation for those in which indirect violence of sufficient force to cause fracture of the spine and paraplegia, will have produced the paralysis through an irreparable injury to the cord. The case reported to-day proves this.

One point to be borne in mind, especially in those cases in which an early operation is contemplated, is the likelihood of other serious injuries than that to the spine being present. Of course error upon this point should be carefully guarded against by a careful examination of the body.

Phelps says: "Recent fractures and dislocations of the spine should be operated. The large mortality should not deter since cases that would surely die or recover hopelessly paralysed may be saved."

Moullin's Surgery says: "In cases of fracture by indirect violence the operation of trephining offers little or no hope. It is probable that in the majority of cases the cord is only subjected to momentary compression, but yet it is so reduced to pulp that recovery of function rarely follows. If it were possible to diagnose the persistence of compression and to relieve it by operation, the condition would be no better and the probability of recovery not in the least greater. This has been confirmed by actual trial in a sufficient number of cases; in fractures of this description the injury to the nerve structures is either so slight than an operation of such a nature is not justifiable, or so severe that it could do no good. In fractures by direct violence, on the other hand, the question is altogether different. The lamina of a spine may be driven in with just sufficient force to compress the cord, without destroying it; and if anything of the kind is suspected, the operation should certainly be performed at once. It has proved its merit. Still more is this the case with the cauda equina. The nerves that compose it may be compressed by displaced bone or cicatricial tissue, and although they possess a power of adapting themselves altogether unknown in the spinal cord, there are limits even to this; and if improvement does not take place, or if in a few weeks it begins to flag, it is open to argument whether it would not be better to expose the seat of injury and, if possible, release them."

From the literature upon this subject one readily comes to the conclusion that here, as elsewhere, circumstances alter cases, and that much care and nicety of discrimination is necessary before one can distinguish the operable from the inoperable cases. The nature, kind and manner of injury seem to be the deciding points for and against operation.

## PERSONAL EXPERIENCE IN THE TREATMENT OF STRANGULATED HERNIA.*

JOHN ASHHURST, Jr., M. D., Philadelphia.

Looking over my records I find that I have operated on nineteen cases of strangulated hernia, and in addition have operated on two cases of irreducible omental hernia, not strangulated. I have, of course, seen a large number of cases where I have succeeded in reducing the hernia by taxis. I have not kept a list of these, but the number is at least as large, if not larger, than the number of those operated on. While the number of my cases may seem small in comparison with that reported by others, this very fact confirms the view which I have always entertained —that strangulated hernia is a rare affection in Philadelphia, and rarer in this country than in the countries of the old world, England and Ireland particularly. Although the cases are few in number, yet following the old maxim—"*Observationes non numerandæ sed perpendendæ sunt*"—It has seemed to me that it might be worth while to bring them before the Academy, so as to introduce the subject for discussion.

Of the nineteen operations for strangulated hernia, fourteen were for inguinal hernia, confirming what everyone knows —that inguinal is the most common form of strangulated hernia, and the one that most frequently calls for operation. One of these cases was in a child, operated on at one of my clinics, and at once removed by the parents, and the further history of that case I do not know. Of the other thirteen patients, ten recovered and three died. The deaths occurred in cases where a fatal termination might have been expected, and were not due to the operation. In one case the hernia had been strangulated for five days and the patient was a pronounced diabetic. He died of gangrene after the operation, dependent upon the diabetic condition and upon the prolonged strangulation. The second death occurred in a woman of seventy-eight years. The strangulation was very tight, and the bowel was gangrenous at the time of operation. Rupture occurred at the sulcus corresponding to the line of constriction, and death took place from exhaustion in the following twenty-four hours. The third death occurred in a man of intemperate habits, who had a hernia strangulated for thirty hours and who had been subject to forcible taxis before admission to the hospital. So forcible had been the taxis that it had resulted in rupture of the bowel in two places. At the operation the scrotum was found enormously swollen and black from effused blood. Twelve inches of the bowel were gangrenous, and the gut presented two openings. I removed the bowel and performed a circular enterrorrhaphy, but the patient died thirty-two hours afterward from cardiac failure, without evidences of peritonitis. It is evident that in none of these cases was the result in any way due to the operation.

Four times have I operated for strangulated femoral hernia, with three recoveries and one death. In the fatal case the patient died in a collapsed condition thirty-six hours after the operation. I have no particulars of the case, but there was no evidence of peritonitis.

I have had one case of strangulated umbilical hernia which terminated fatally. The patient was eighty years of age, and the strangulation had existed for a number of hours. The patient died of peritonitis, which, as we all know, is particularly apt to occur as a complication after umbilical hernia, incisions into the upper portion of the abdomen being more apt to be followed by peritonitis than incisions in the lower portion.

The youngest patient on whom I have operated was a child two years of age, with inguinal hernia. This case ended in recovery. The oldest patient was the woman eighty years old, with umbilical hernia, just referred to.

Among cases of special interest I would mention one of the inguino-crural variety,

* Read before the Philadelphia Academy of Surgery, May 7, 1894.

where the hernia after coming down through the inguinal canal does not pass into the scrotum, but turns up in the line of Poupart's ligament and passes outward along the groin. It is usually complicated, as it was in this case, with an undescended testicle. In this case the hernia had been down six days when I operated. I was able by taxis to reduce a portion of the tumor, but finding that there still remained a hard mass which could not be reduced, I thought it right to open the sac and determine the exact condition. I found that the hard lump was the testicle in a gangrenous state, either from a twist in the cord or, as seemed more probable, from the taxis which had been practised rather violently before the patient's admission to the hospital. I excised the testicle and the patient recovered.

I have operated in two cases of irreducible omental hernia. In these cases a tumor had been present in the tunica vaginalis for a long time, and while there were no symptoms of strangulation, the weight and bulk of the tumor gave great annoyance, and the patients were exposed to the risk of a portion of the gut coming down at any time. I therefore, felt justified in operating in these cases, cutting away most of the omentum after securing its neck between two ligatures.

The points of special interest in the treatment of strangulated hernia which I would suggest for discussion are, as regards the resort to taxis, its limitations and the aid to its performance, and then as regards operative treatment, the particular mode of performing the operation, more especially as regards the direction of the deep incision, in regard to which some difference of opinion prevails, and as to the advantages and disadvantages of Gay's method as modified by Fergusson, and as to the advantages or disadvantages of Petit's plan of operating without opening the sac.

*The limitations of taxis.* I feel obliged to say that while I have reduced a good many strangulated hernias by taxis, while I think that it should be the surgeon's first thought, and while if practised with care and skill it is a safe method and one which will usually succeed when resorted to in time, yet I must express my belief that in the hands of an inexperienced practitioner, who sees but few cases of hernia, taxis is an unsafe procedure. Under such circumstances, I think that the patient would sometimes be safer with the operation of herniotomy than with taxis, for herniotomy is not a very difficult operation and not very dangerous if performed with caution, whereas taxis, while seeming to be very simple, yet if employed with great persistence and force may lead to the most serious consequences. My own cases of herniotomy which resulted fatally had been mostly subjected to prolonged taxis. Taxis, therefore, I think has its limitations, and should be resorted to with great gentleness and with great caution, except in the hands of those surgeons who are sufficiently familiar with the anatomy and treatment of strangulated hernia to feel that they may use the method more freely and more systematically. It is, of course, known to the Fellows of the Academy that its founder, the late Professor S. D. Gross, maintained that very few cases of hernia required operation. He prided himself that he was able to effect reduction by taxis where others had failed; and such was undoubtedly the case. In the hands of a man like Professor Gross, taxis was a safe procedure, but in the hands of the ordinary practitioner I believe that the line of safety for the patient will be often found in herniotomy rather than in a prolongation of taxis.

It is scarcely necessary to say that when taxis is employed it should be done with gentleness and with system. The ordinary method of pushing at the hernia is very uncertain, and is not only apt to do harm but is almost sure not to do good. The rule that the last portion of bowel which has come down should be first returned is very valuable and should always be borne in mind. Then I find what I am in the habit of speaking of to students as a kind of conjoined manipulation, a very useful mode of applying taxis, and I think the safest. The neck of the sac is grasped by the thumb and fingers of one hand, while the other hand, spread out, exercises a combination of pushing and squeezing; and then by a kind of alternating movement, slightly relaxing one hand while with the other the pressure is increased, if the hernia is reducible at all, it will go up. If no gurgling is heard in a few minutes it is not likely that taxis will succeed.

As regards the *aids to taxis*, the older surgeons resorted to many modes of as-

sisting taxis, but in modern times surgeons have pretty much come down to two or three. Even the warm bath, which was much resorted to formerly, I think is seldom employed at present. At the Pennsylvania Hospital, our practice is to put the patient in bed, apply ice over the hernia, and give a moderate quantity of opium. When the resident physician is not able to reduce the hernia by gentle taxis, this course is followed until the surgeon has been summoned. It often happens that when the surgeon arrives he finds that the hernia has been reduced spontaneously or disappears under the slightest touch. If this fails, our rule is to administer ether and again employ taxis, and in this way the hernia can usually be reduced. Before administering ether we have an understanding with the patient that if taxis does not succeed then the operation is to be resorted to.

Another manipulation which is of great importance is to draw down the hernia a little before beginning the upward pushing movement, the object being to disengage the portion of bowel which is nipped by the source of constriction. The plan known as Seutin's I have never seen of avail, and I can hardly conceive of a case where it would be required in which it could be used successfully. This plan consists in endeavoring to introduce the finger or thumb-nail into the constricting ring, which is then stretched; this could be practised only in very thin persons, and where it could be done I think it probable that taxis would succeed without it.

With regard to *herniotomy*, the first question that will have to be decided is the extent of the external incision. Some operators make a large incision, extending over the entire length of the hernial tumor. Others endeavor to effect the operation through a very small incision, as in Gay's method. My own plan is to make the external incision three or four inches in length, and over the neck of the sac. As regards the particular method of making the incision, whether by pinching up the tissues, transfixing, and cutting outward, or by cutting down from without, I really think that there is no choice. My own practice is to employ the latter plan. Having gone through the skin and fascia, the surgeon, of course, takes up the tissues cautiously, dividing them on the director. The next question is to whether or not the sac shall be opened. I agree with the English rule, that where it is justifiable to resort to taxis it is proper to endeavor to reduce the hernia without opening the sac. I have often tried to do this, but have been compelled to open the sac, as the constriction has been in its neck. In making the deep incision the tip of the left forefinger should be pressed against the source of constriction and the hernia-knife passed flatwise; this is then turned in the proper direction and the deep incision made with a gentle sawing motion, assisted by pressure of the finger below. I am satisfied that the rule of the English surgeons, to make the incision directly upward in inguinal hernia, is the correct one. While in a certain number of cases the surgeon can say this is a direct, or this is an oblique hernia, yet in other cases the relation of the parts is so confused that he cannot be absolutely certain which form of hernia he is dealing with. In the one case the internal epigastric artery will be on the inside and in the other on the outside. The safe rule, therefore, is to make the incision directly upward and in the line of the long axis of the body. In femoral hernia the deep incision should be made upward and inward. It is only in this direction that we are safe from doing injury and certain to reach the source of constriction, this being where the falciform process and Gimbernat's ligament join. The only danger from hemorrhage when this plan is followed is from an abnormal distribution of the obturator artery. To avoid wounding this, a good plan is to adopt Mr. Erichsen's suggestion to blunt the edge of the hernia-knife by rubbing it on the handle of another knife, or as suggested by Dr. Wyeth, to keep the point of the knife firmly pressed against the pupis.

In umbilical hernia the safe line of incision is in the median line, and directly downward. The operation is apt to be followed by peritonitis under any circumstances; but I think that there is less danger if the incision is made in this way, on the general principle that wounds in the lower portion of the peritoneum are less likely to be followed by peritonitis than those above. In the case on which I operated the hernia was of long standing, but the strangulation was recent, from the protrusion of an additional portion of bowel. There I followed the judicious

rule of not attempting to reduce the whole hernia, which would have required an extensive dissection, but simply relieved the strangulation and returned the part recently protruded.

With regard to the method of dealing with the contents of the hernia, I think that all surgeons agree that if the bowel is healthy it should be returned, but that if gangrenous it should be left in the wound and a false anus formed. If a distinct sulcus is found I think that it is a good rule not to reduce the bowel, so that if it should give way the extravasation may be outside of the peritoneal cavity. As regards the omentum, I think that it is a safe rule to cut it away pretty freely. If it is perfectly healthy it is proper to return it, but if there is doubt it is safer to remove it.

With regard to after-treatment, I am sure that the safest mode is not to make any attempt to get the bowels opened. Some surgeons are in the habit of giving a dose of oil immediately after the operation, and some even before the operation; but this seems to me to be injudicious. I put the patient on the use of opium and belladonna for a few days, gradually diminishing the dose, and usually the bowels move spontaneously in five or six days.

The number of cases which I have brought before you is limited, but they represent a sufficient variety to perhaps be available for the discussion of some of the points suggested.

## NINE CASES OF CONTUSIONS AND SPRAINS OF THE BACK, WITH SPECIAL REFERENCE TO THE EARLY TREATMENT OF THESE INJURIES.*

HENRY R. WHARTON, M. D.,† PHILADELPHIA.

During my term of service in the Presbyterian Hospital in 1892, there were admitted to the surgical wards nine patients who suffered from contusions and sprains of the back, and it has occurred to me that a short description of the method of treatment, which I have employed with the most satisfactory results in this class of injuries, might be of some interest to the Fellows of the Academy.

CASE I.—J. P., aged twenty-eight, gardener, who was admitted to the hospital May 5,1892,received a blow upon the back in the left lumbar region from a heavy wooden tub, which caused him severe pain. An examination after admission proved that there was no injury to the spine, but there was intense pain upon pressure in the left lumbar region, and also severe pain upon motion. The patient's back was strapped with adhesive plaster, and two days afterward he was able to sit up with comfort, and he was discharged from the hospital on May 9th.

CASE II.—H. P., aged nineteen years, fireman, was admitted May 12, 1892, with the following history: While standing on the edge of the tender of a locomotive he slipped and fell between the tender and the station platform; the engine was moving at the time, and he was rolled between the tender and platform, being severely squeezed in the lumbar region.

Upon examination after admission, no fracture of the spine or pelvis could be detected, but the patient complained of intense pain in the back, was unable to stand, and suffered from retention of urine. The back was firmly strapped with adhesive plaster. Upon introducing a catheter, a large quantity of bloody urine was drawn from the bladder, and after this the patient passed the urine voluntarily, which was deeply tinged with blood for four days. The patient improved steadily, and was discharged from the hospital on May 27, being able to walk, but still having some tenderness in the lumbar region, this part being still supported by means of adhesive straps.

CASE III.—J. G., aged twenty-five years, steam fitter, was admitted on May 20, 1892. The patient stated that while boarding a moving train at Powelton

*Read before the Philadelphia Academy of Surgery, May 7, 1894.

†Surgeon to the Presbyterian, Methodist Episcopal, and Children's Hospitals, Demonstrator of Surgery at the University of Pennsylvania.

Avenue he was thrown against the milk platform, striking his back and shoulder. An examination, on admission, showed slight contusion of the shoulder and marked contusion and tenderness over the lumbar region. The patient was unable to walk, and complained of severe pain upon pressure and upon making any movements. The back was strapped, which gave great relief. The patient also suffered from retention of urine, requiring the use of a catheter. The patient was discharged in good condition on June 4.

CASE IV.—D. D., aged forty-three years, bricklayer, was admitted to the hospital on May 23, 1892. The patient stated that while standing on a platform sixteen feet high, laying brick, the wall was pushed over by a derrick and he was thrown to the ground, striking upon his back. An examination after admission showed marked contusion of back and shoulder, great tenderness upon pressure and motion, and some tenderness over the spinous process of one of the lower dorsal vertebræ. The back was strapped, which gave great comfort. The patient was kept in bed for a week, and was discharged on June 6, in good condition.

CASE V.—R. C. W., aged twenty-seven years, brakeman, was admitted to the hospital on May 28, 1892. The patient stated that he was knocked off the top of a car on which he was riding, and was thrown to the ground, striking upon his back. On examination there was marked contusion of the back in the lumbar region, tenderness upon pressure, and inability to stand or walk. The patient's back was strapped, which gave him marked relief, and he was discharged on June 30th.

CASE VI.—A. W., aged twenty-eight years, trucker, was admitted to the hospital on May 31, 1892. The patient stated that while moving a heavy slab or stone, it fell and struck him upon his back. An examination after admission to the hospital detected no fracture of the vertebræ, but there was great soreness and tenderness on pressure in the lumbar region. The back was strapped, and the patient was discharged from the hospital on June 3d, in good condition.

CASE VII.—J. C., aged nineteen years, iceman, was admitted to the hospital on June 12, 1892. The patient stated that he slipped while crossing the street, and fell, striking his back upon the curbstone. He was unable to walk, and was brought to the hospital by the patrol. Upon examination after admission it was found that the patient had great pain in the left lumbar region, but there was no evidence of fracture of the vertebræ. The back was strapped, which gave him immediate relief. This patient suffered from retention of urine, and upon evacuation of the bladder it was found that the urine was bloody. The blood disappeared from the urine in a few days. The patient did well, and was discharged on June 14th.

CASE VIII.—W. McN., aged thirty-five years, brakemen, was admitted June 22, 1892. The patient stated that in a freight wreck at Tacony the car on which he stood was thrown from the track, and he was thrown to the ground, striking upon his back. An examination after admission showed that he was suffering from contusion of the back and foot. The back was strapped, and the patient was discharged, in good condition, on June 25th.

CASE IX.—L. B., aged twenty-five years, was admitted to the hospital June 25, 1892. The patient stated that while standing on top of a freight car he was knocked off by the Spring Garden street bridge, and was thrown to the ground, striking upon his back. On examination after admission, he was found to be suffering from severe contusion of the back, but there was no evidence of fracture of the vertebræ. The back was strapped, which gave him marked relief. The patient also passed bloody urine. The patient did well, and was discharged on June 28th.

It will be noticed in the above cases that the lumbar-dorsal region of the back was the part most frequently injured, and this part seems to be that which was most commonly the seat of contusions and sprains. As regards the treatment of contusions and sprains of the back, I consider that rest in bed is a matter of the first importance, and in addition I have found that the pain and general discomfort of the patient is much diminished, and the time of treatment much shortened by having the back firmly strapped as soon as the patient came under observation. The strapping of the back is effected by taking strips of resin-adhesive or of rubber-adhesive plaster, 2½ inches in width, and long enough to extend half way around the body; these are applied so as to cover in

the back, one strap slightly overlapping the other, from a point just below the junction of the last lumbar vertebræ with the sacrum to the lower ribs. These straps were often removed at the end of two or three days, and the back was restrapped if the pain and tenderness still persisted. The straps were usually allowed to remain in place until the patient was up and about, without complaining of pain or discomfort in the region of the injury. In cases of severe contusion the straps often require renewal a number of times.

This method of treatment of contusions of the back was first called to my notice by Professor Ashhurst while serving as resident physician in his wards at the University Hospital, and since I have employed it I have entirely discarded the use of fomentations and stimulating lotions, which are generally recommended in the treatment of these injuries.

The treatment usually recommended in contusions and sprains of the back is warmth, frictions, stimulating liniments, anodynes, acupuncture, galvanism, and massage, and of these I think massage is the most valuable, employed after the acute symptoms following the injury have subsided; but in early stages of these injuries I am convinced that strapping will be found the most satisfactory method of treatment.

I have observed that the application of straps employed as above described is usually promptly followed by relief of pain, and the fixation produced allows the patient to move with more comfort, and I am very certain, after having now employed this method of treatment in a considerable number of cases, that the time required for the recovery of the injured parts is much shortened. It will be observed, by referring to the cases reported, that many of them were comparatively trivial injuries, and the patients recovered in a short time; but even in this class of cases the suffering is often very intense for the first few days. It will also be observed that Cases II, VII, and IX passed bloody urine for a few days after the injury, showing that the injury had been severe enough to produce laceration or contusion of the kidney. Lidell‡ in his very excellent article upon contusions and sprains of the back, speaks of the frequency or hæmaturia in these injuries when powerful blows have been delivered upon the lumbar or dorsal region of the back. The recovery, as far as I know, in all of the cases reported was satisfactory, except in Case IV. In this case the patient developed, some months after leaving the hospital, symptoms of traumatic neurasthenia, complaining of pain in the back and head, and vertigo, and brought suit against the contractor for whom he was working at the time of the injury. From what I heard of this case, and from the fact that when it was ascertained that the patient was doing his ordinary work, the suit was settled for a trivial sum, I am inclined to think that the symptoms developed were not severe, and might be classed as litigation symptoms.

In cases of severe contusion or sprain of the back when there is inability to stand or there is present great pain on motion, and where tenderness over the spine and a certain amount of fixation is present after the injury, I think there is too much tendency to attribute the symptoms resulting to an injury of the spinal cord or membrane, which injuries when unaccompanied with fractures of the vertebræ are extremely rare; whereas the injury resulting to the muscles, ligamentous structures, and nerves, with perhaps the renching and laceration of the vertebral articulations, is perfectly possible to account for the symptoms resulting, and I agree with Mr. Page, that many of these cases are well described by the term "traumatic lumbago."

As contusions and sprains of the back are injurious which are often followed by the development of symptoms which are described as traumatic neurosis, or traumatic neurasthenia, it seems to me that these are cases which should be carefully treated when they first come under the observation of the surgeon, for I am sure that many of these cases if so treated by rest and fixation for a short time would make more complete recoveries, and would be less likely to develop the symptoms above described. In cases of contusions or sprains of the back in which symptoms of traumatic neurasthenia develop, and which give rise to litigation, it is often difficult for the surgeon to estimate how far the original shock of the system following the injury is responsible for the symptoms presented. In many cases the

‡International Encyclopædia of Surgery, vol. iv., p. 700.

objective signs presented leave no doubt of the severe nature of the injury, while in other cases the symptoms complained of are mainly subjective in their character, and these are the cases which give rise to the most troublesome litigation. It is often difficult to decide whether the symptoms presented are merely assumed or exaggerated for fraudulent purposes, or whether, without any attempt to deception on the part of the patient, injuries trival in themselves may be unconsciously exaggerated, and be apparently productive of serious results. Although many severe injuries of the back apparently recover without developing such symptoms as have been described, there is no doubt that the element of compensation for the suffering and disability from the injuries received plays an important part in the exaggeration of these symptoms, and that expectancy may be justly credited with an important place in their exaggeration. In cases of serious disorder resulting from contusions and sprains of the back, often apparently trival, the symptoms developing are usually progressive in their character, and soon there will become manifestly marked objective signs, such as paralysis, disturbances of the reflexes, loss of electrical excitability, disturbances of the bladder, loss of flesh, sleeplessnes, etc., which place the existence of morbid changes beyond a doubt.

# TRANSLATIONS.

## HERNIA OF THE LIVER.

Dr. Kusmin—(*Berlin Klin Wochen*, 1893—44,) reports: the patient æt 28, female, sought relief for a painful tumor, located between the umbilicus and the scrobiculus cordis, 25 c. m. in diameter. A diagnosis of hepatic hernia was made and proved correct at the operation. The hernial sac contained a liberal amount of fluid and a portion (circular) of the left lobe of the liver incarcerated. Reposition after the needed enlargement of the hernial canal; radical operation cure. Seven months later no signs of return. The patient had never worn a corset, but always had tied her skirt bands very tightly. —W.

## SUCCESSFUL EXTIRPATION OF A NEW GROWTH FROM THE LIVER.

D. J. Rosenthal reports (*Gaz. Lekarska* 1893, No. 45): Patient, female æt 41; had noticed for some weeks a tumor in her abdomen, finding herself at the same time growing much weaker. An examination revealed a hard movable tumor below the navel about the size of a child's head; it seemed to have no connection with the liver or genital organs. An operation was decided upon. Trendelenberg position showed the tumor to be attached to the left lobe of the liver; it was hard, nodular, of a bluish-brown color, it was covered anteriorly by the gall-bladder; its size was about as large as the head of a two-year-old child. The gall-bladder was pushed to one side and the adhesions between liver and tumor gently separated. At this stage the operator was certain beyond a doubt that the growth had started in Spiegel's lobe. The swelling was brought out through the abdominal opening, an elastic ligature passed around the pedicle, which was further fastened to abdominal walls treated extra-peritoneally. The patient made a good and uninterrupted recovery; the growth examined microscopically proved itself to be a fibroid angioma.

## THE TECHNIQUE AND RESULTS OF RESECTION OF THE STOMACH.

Dr. Kocher reports 6 cases performed during 8 weeks for carcinoma (2 Gastroenterostomies, 4 resections of the stomach,—all resulting in a primary union). In connection with the report of these cases he presents an exhaustive study of the different operations together with their ultimate results. The question regarding the operation of election (gastroenterostomy or pylorectomy), he answers, that, by careful and scientific improvement in the technique of resection a more probable radical cure can be achieved, than by the palliative operation. Gastroenterostomy however may afford much relief in advanced cases of carcinoma and also be of great use in many instances where structures due to cicatricial or fibrous tissue exist, and in these last mentioned cases the preferable operation owing to inaccessibility of the pylorus often made more so by abnormal adhesions. The author then describes his method of operation—he follows Hacker rather than Wolfler—known as the gastroenterostomie antecolica anterior; the upper loop of the jepeinum is attached to the stomach in its transverse diameter, permitting the tube to have its natural position, the upper end above the lower end below. In uniting the stomach with the intestines great care should be exercised that the intestine is opened transversely on its convex surface. The ultimate results of gastroenterostomy, when done for carcinoma, has given the patient never more than one year, more often less; while on the other hand resection of the pylorus proved more successful. Wolfler has reported an interim of five and-a-quarter years; Billroth, two and-a-half and one and-a-half years; Rydygier, two and-a-half years, while the author's patient at five years and four months is still enjoying good health.

The author has operated on sixteen cases; in two of these he followed the method set forth by Billroth, gastroenterostomy, followed by resection of the pylorus; in nine other cases he excised the carcinomatous pylorus, first fitting the duodenum into the opening of the stomach. Two patients of this number died from the effects of the operation; one survived ten months and died from carcinoma of the liver. There was no trace of any recurrence. The remaining six cases recovered from the operation without any unpleasant symptoms, and are still living and enjoying good health.

The author names his operation "pylorus resection," with gastro-duodenostomy, and describes his operation as follows: A median incision (10 to 15 cm.) beginning a little above the umbilicus and extending downward, care being taken to excise the navel and arrest all hemorrhage, all adhesions carefully separated, and the tumor drawn out and clamped, two clamps at the duodenal and two at the gastric end of the tumor; the growth is then excised. The assistant then grasps the stomach behind the clamps, between index and middle fingers of both hands; the operator then cuts through close to the clamps, the free edges of the stomach are united and closed by the continued Lembert's suture and dropped.

The assistant again takes hold of the stomach with both hands, directing its posterior wall toward the right and anterior.

The clamp is still allowed to remain on the duodenum while its posterior surface is sewed (a continuous suture) to the posterior wall of the stomach; the clamp is then removed from the duodenum, its edge trimmed properly, an opening made into the stomach corresponding to that in the duodenum, and the anterior edges of both organs united, after cleansing the field of operation, the stomach and intestines are dropped, and the abdominal wound closed.

The important features necessary to insure a successful result, are as follows:

1. The operation must be strictly aseptic in all its details.

2. The continued suture is of the utmost importance, (Rydygier Lauenstein), the suture enclosing the entire thickness of both stomach and intestinal walls, thereby avoiding absolutely all secondary hemorrhage. The suture material consists of fine silk.

3. Kocher considers the use of the clamps of great importance, because they tend to simplify the operation, and aid in excluding the carcinomatous tissue. Another point which he makes in their favor is that they act as a guide in making a *straight* cut.—*Centralblatt of Chirurg*, No. 10, 1894.

TERMS:—Three Dollars a year, strictly in advance. Sent four months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JUNE 23, 1894.

## EDITORIAL.

### THE WOMAN IN SCARLET.

The REPORTER is led to make these remarks by observing an anachronism contemplated in a modern community. It is a serious proposal to gather figs from thistles and grapes from thorns; to harvest public good from the lava beds of public vice. All that is deemed necessary is to turn up the ashes and cinders of the social evil with that antiquated crooked-stick plough, licensed regulation.

Ignoring all past experience, the Board of Public Safety of Louisville, Ky., desires to try its hand at moderating the evil by licensing and regulating prostitution. It is precisely the plan that has been so often tried with an inevitable result in failure. In one respect it appears possibly an improvement on previous experiments, in so far as it proposes to devote all sums accruing from the licensing of disorderly houses to the maintenance of a home for fallen women. A moment's consideration of this feature, however, shows it to be specious if not ridiculous. We doubt very much whether the people in Louisville can thus be reconciled to giving legal sanction to immorality, especially as the whole plan is based upon a conceded failure.

In the United States there has been but one prominent experiment in this line. A four year's trial of the system in St. Louis, Mo., proved it such a colossal failure, that it was gladly abandoned. A similar attempt, but on a smaller scale, has been made in Cleveland, with the usual result of increasing the evil sought to be diminished. But in Europe the system has been most thoroughly tested over a number of years, with the positive conclusion that the licensing and regulation of prostitution has in no wise diminished the number of prostitutes, and on the other hand has apparently been responsible for the marked increase in venereal diseases. In England the system was abandoned as a failure after a most careful study of the subject in all its phases. On the Continent, the plan is still nominally in force, but indications are that it is on the point of being abandoned there likewise.

It is not our intention to discuss the

question in all its bearings, but simply to call attention to that part of it which relates especially to the medical profession. It will be observed that the most weighty reason urged in establishing every system of restricting or regulating prostitution, has been the assumption of its necessity as a sanitary measure. The burden of responsibility for the influence of this assumption rests with the medical profession. In the practical treatment of prostitution, it is impossible to separate the physical from the ethical and social elements of the condition to such an extent as to justify ignoring any one of the three in attempting to effect a cure. It therefore behooves medical men to be well posted on the entire subject before venturing to express an opinion or to advise any line of treatment.

Open prostitution is but one expression of the social evil. There are many who believe that if not created by the conditions which tolerate and perpetuate it, it has developed so that now these conditions actually necessitate it; and that it is impossible to eliminate this form of immorality and preserve intact those features of social life which are responsible for its existence. Social relations is a complex subject for study and discussion by the most thoughtful observers, and it has come to pass that a group exists of alleged reformers, who in literature love to be known as realists, whose business it is to stand on the verge of the abyss and, pointing out its many horrors, seek to convince humanity that salvation can be accomplished only by tearing down all the safeguards erected during a long existence of sorrow and struggle and, casting them in, fill up the bottomless pit. These realists generally exhibit the unfortunate conditions of human life truthfully. It is only when they attempt to draw logical conclusions from their incomplete premises, that they display a woeful incapacity to take a comprehensive view of life.

An eccentric Russian pessimist of this class, whose sincerity is much more trustworthy than is his judgment, has made a terrible presentment of the part taken by the medical profession in hastening the degeneration of mankind. The sentiments are worthy of the insane uxoricide into whose mouth they are put, but there is suggestion in them well worthy of the careful thought of all medical men. If not actually true, they might easily be made so, and the responsibility exists, whether they are true or not.

Tolstoi makes the dissolute Posdnicheff say:—

"True, there are ten commandents between the boards of the Bible, but they are only made to be recited before priests and tutors, and not nearly of as much importance as are the rules of grammar."

"So I have never heard my elders, for whose opinions I had a due respect, speak of concupiscence as a sin. On the contrary, I had often heard it boasted of. I was told that, once gratified, my passions would leave me in peace. I was told so, and I had read it in books. My elders said that health required it, and all my companions seemed to believe that it was something to be proud of. As to my danger of infection—that was the government's business—that point was guarded against. It regulates the concerns of the tolerated houses of prostitution. It assures the safety of debauchery to young and old. Salaried physicians are employed to guard us from the natural consequence of sin. It is all of a piece. We are told that incontinence is good for our health, and therefore prostitution is made lawful. Why! I know mothers who take care that their son's health should not suffer from too much virtue. Science itself canvasses for houses of prostitution."

"Science! how can that be?" I asked.

"Are not physicians the high priests of science? Who perverts young people by prescribing sexual intercourse? Who

teaches women to avoid having children? Who cures the guilty, when the sin overtakes them? The doctors! The priests of science."

"But why should we not succor the sick?"

"Because to cure the malady is to encourage its cause. It is on a par with all foundling hospitals."

"But—"

"If one hundredth part of the care was taken to cure sin, that is wasted to cure the sickness, disease would have died out long ago. All our efforts are devoted, not to extirpate debauchery, but to favor it by guaranteeing the safety of sinners."

And again, speaking of the doctors, this interesting lunatic says:—

"I neither like nor dislike them. They have ruined my life, as they have ruined the lives of millions before me, and I cannot help looking from the effect to the cause. I understand that they, like lawyers and other professional men, must make their living somehow, and I would have willingly given the half of my fortune, as others would if they knew as much as I do, on condition that they would keep their distance and not mix themselves with my affairs. I am not a statistician, but I know dozens of cases where doctors have killed, sometimes an infant in its mother's womb, on pretense she would die in childbirth (and, nevertheless, the same woman bore many children afterwards with perfect safety), sometimes the mother herself, under the pretext of a so-called operation. The world takes no account of these assassinations, just as it took no account of the cruelties and murders committed by the Inquisition, because they are supposed to be perpetrated in the interest of humanity. Innumerable as the stars of heaven are the sins of doctors. But all their crimes are nothing compared to the materialistic demoralization with which they poison the world through woman. I do not speak now of that materialism that refers everything to microbes and bacteria, and, instead of tending to the preservation of humanity, would lead to its dissolution. According to these theories, everybody should live in a perpetual quarantine, with a disinfecting pad under his nose, although, by the way, scientists have discovered now that even this is ineffective. But I will give them the benefit of the doubt. This supreme poison is the perversion of the human race, and, above all of woman.

"You can't say in these days, 'Your life is evil; reform it,' because doctors will tell you that the cause of evil is derangement of the nervous system, or a lesion of something somewhere. And you hurry to consult them, and, for a fee graduated according to their position in the profession, they will prescribe drugs from the apothecary, which you will swallow with a wry face. You get worse and worse; you consult another doctor; he will say the former treatment was all wrong, and will give you quite a new variety of nauseous doses, and your mind is relieved, and your body—well, never mind about your body."

A truly pessimistic nightmare, but a vivid relation of the powers and responsibilities of medical men.

Concerning the regulation of prostitution, medical men know that, no matter how faithfully carried out the provisions may be, all systems have so far proved unavailing. Where public prostitution temporarily appears to diminish, clandestine prostitution increases enormously. The attempt to prevent the spread of disease by the compulsory medical examination of registered harlots, is an utter farce. Statistics have shown us that under all systems thus far devised, immorality and disease have increased. The reasons are obvious without stating them.

Now if the Board of Public Safety of Louisville, is sincere in its desire to

restrict immorality and to prevent the spread of disease, and is not endeavoring to concoct some boodle scheme, we would suggest the invention of some new method, rather than wasting energy in making a new demonstration of an assured failure.

Destructive criticism is a very much easier undertaking than is the suggestion of something better to take the place of the subject criticised; but we think that a candid consideration of the methods heretofore unsuccessfully employed to mitigate the conditions complained of, will develop some of the reasons for the inevitable failure that has attended all efforts to restrict prostitution by regulation. The frank appreciation of the causes of the failure will naturally develop some suggestions for obviating them. The REPORTER therefore modestly offers to sociologists and professional reformers, an outline of a treatment for this unhappy disease, which is not copy-righted and the details of which can be made to suit varied requirements. As a system it would at least have the advantages of novelty, of producing a powerful impression, of rapidly crystalizing public opinion for or against it, while if it did not prove more effective than the older plan, it could not be a greater failure.

We submit that any authorities who would designate a certain locality as a centre and source of infection and would freely allow admission to and exit from that locality of all and sundry parties without any reference to their bringing to or taking from it an infectious disease,—as, for instance, cholera,—and yet would seek to protect the community against this disease by periodic examinations of the locality itself, to see whether infection was evident there—any authorities who would expect such methods to do else than assure the spreading of the plague, would confess themselves incompetents whose proper place is in the insane asylum. This is practically all that is attempted by any tried system for regulating prostitution by license and supervision. The so-called sanitary precautions undertaken have had for their sole object the protection of the male prostitute. It is true that the harlot may become a nidus of infection which will spread in all directions, but it must be remembered in her case, that the specific infection is not autogenetic; that it must be brought to her; that she is not the immediate carrier of infection who spreads it broadcast. Every experienced physician knows that the female prostitute may be capable of conveying infection of the most virulent type without exhibiting in her own person any indications of the existence of the disease. Furthermore he knows that there are multitudinous appearances which simulate disease but which are not of themselves infectious. Even where the indications of the disease may be present there are anatomical reasons making it extremely difficult to arrive at a positive diagnosis, unless the lesions are very pronounced.

Now comes the factor that has hitherto been religiously ignored. We are assured by those whose investigations render their statements authoritative, that, at the very lowest calculation, their exist for each female prostitute, four or more male prostitutes. Physicians know this to be true from their personal experiences in practice. They know that the detection of specific disease is relatively much easier in the male than in the female. They know furthermore, that it is the male prostitute that acts as the direct carrier of specific infection, and that upon his shoulders must be placed the responsibility for introducing disease to others entirely innocent, who must bear the disasterous consequences which ignorance entails upon specific disease neglected.

The gist of the whole matter is that to redeem the good name of preventive medicine in this particular field, protec-

tion must be given to the female prostitute, fully as efficient as that afforded to the male. If there is any good to be obtained by compelling the registration and medical certification of the female prostitute, by all means obtain it. But extend the regulation and supervision to the male prostitute as well, so that each may beware of the other.

A chimercial scheme truly, but one worth trying, if for no other purpose than to demonstrate its fallacy, and because on the surface it presents quite as much promise as anything thus far suggested in the way of governmental control.

We would therefore advise our Louisville friends to arrange matters in such a manner that something like the following may be put into effect:

At frequent, irregular intervals, make unexpected raids upon the disorderly houses. Place in custody all males found therein, without fear or favor. It is unnecessary to molest the females, who are supposed to be already under public supervision. Having arrested the male prostitutes, inflict such penalties in the way of fine or imprisonment as may be deemed desirable, or dismiss them with a warning; but under no circumstances whatsoever should they be discharged until they have been PHOTOGRAPHED in addition to the ordinary memoranda of identity. Next in importance to securing the photograph would be the compulsory submission to a thorough medical examination. Should no evidence of disease be observed, discharge the prostitute with strict injunctions to present himself in person for medical examination at suitable intervals until the known period of incubation, starting from date of arrest, shall have passed. There will be no trouble about these subsequent examinations when the prostitute learns that a failure to undergo them would entail the exposure of his photograph as a warning to the public that the original is to be ragarded as a possible source of infection, and, therefore, a menace to the community. If at the end of his period of observation, the individual is found free from infection, his photograph and all memoranda obtained by the health authorities may be returned to him without any violation of privacy.

Should the prostitute, at the first examination, display evidence of disease, he should be subjected to quarantine measures of more or less severity. In mild cases, perhaps, the display of his photograph in the offices of the Health Department and in the various disorderly houses, would be sufficent. At any rate, some such method would afford prostitutes of the other sex efficient protection by enabling them to immediately identity probable carriers of contagion.

The key to the whole business lies in the photograph and its skillful manipulation.

It must be understood that we are suggesting measures that would prove effective from the standpoint of public health alone. We do not pretend to say what effect such methods would have other than as sanitary precautions. The effect of putting some such scheme into operation can be better imagined than described; but we venture to say that three such raids made effectively, and the quarantine measures enforced without fear or favor, would settle the question of *public* prostitution in any city in America.

This plan is barely suggested, but it opens up possibilities for the effective treatment of the social evil that are not contemplated in any of the measures that seek to conserve the public health by supervising a small fraction of the individuals afflcted with the disease.

Make the measures rational, or cease prating about the sanitary necessity of regulating prostitution.

# SOCIETY REPORTS.

## PHILADELPHIA ACADEMY OF SURGERY.

*May 7, 1894.*

Dr. Ashhurst read his

PERSONAL EXPERIENCE IN THE TREATMENT OF STRANGULATED HERNIA.

See page 876.

DISCUSSION.

DR. JOHN B. DEAVER: I cannot add anything to what has been said by Dr. Ashhurst. I would ask the experience of the Fellows with reference to anastomosis. I believe that anastomosis operations are of value in but few cases of strangulated hernia. I have tried the method more by way of experiment, but the cases have not recovered. In order to do this operation it is necessary to pull down additional bowel. As Dr. Ashhurst suggests, where this sulcus has formed it is better to allow the bowel to remain in the wound or, as I prefer, to cut it away. In hernia the condition of the patient does not warrant the procedure of anastomosis, and even under the most favorable circumstances the operation is anything but satisfactory.

I remember a case of strangulated femoral hernia on which I operated some years ago. The bowel was completely separated, so that I could not find the proximal end through the opening made in exposing the hernia. It was necessary to open the linea alba to find it. There was extravasation of feces into the peritoneal cavity; here I did an anastomosis, but it was not successful.

I believe that we all agree that it is unwise to move the bowels immediately after the operation for strangulated hernia where the condition of the bowel is questionable and where increased peristalsis would favor rupture.

DR. J. M. BARTON: Dr. Ashhurst has had better fortune with taxis than I have had. One reason is perhaps that I have not spent much time with taxis. I have so often found the bowel in such a doubtful state, even after short strangulation, that I feel much safer, if there is any question as to its condition, to operate at once under antiseptic precautions. In one case the bowel was entirely gangrenous eighteen hours after the violence that produced the strangulation.

As to the advisability of making lateral anastomosis immediately after removing gangrenous bowel, the condition of the patient rarely warrants any prolonged operation, and I think that the rule now is, in intestinal obstruction, irrespective of cause, to do nothing further than establish an artificial anus at the first operation. I have devised an instrument for use in these cases. It is a modification of Dupuytren's enterotome. It can be adjusted in a moment, and is intended to make an intestinal anastomosis, allowing the artificial anus to remain as a safety-valve. Since devising the instrument I have not had a suitable case in which to apply it.

DR. O. H. ALLIS: I think that we all agree in what has been said about the use of forcible taxis. I remember an instructive case operated on by Dr. Hearn. It had been sent to the hospital after severe and prolonged taxis had been used. The constricted portion lay in the hernial canal, and he was obliged to cut down on it at that point. It was impossible to pass a grooved director between the constriction and the gut, so firmly had it been wedged. In two other cases I have seen the gut driven back and forced between the peritoneum and some of the layers of the sac, and in that way while the physician felt that he had reduced it he had only masked the trouble and made it more certainly fatal.

With regard to umbilical hernia I would state that I have had there three cases and have never seen such a case die. I should be glad if the Fellows would tell us their experience with umbilical hernia.

DR. H. R. WHARTON: I think that the most difficult point to decide in the treatment of strangulated hernia is the question whether or not to put the bowel back when it shows the marked effect of strangulation. In many cases where there is not absolute sloughing, it is hard to decide whether or not a bowel whose nutrition is much impaired will recover. Within the

past ten days I have had a case of femoral hernia where the color of the bowel was very unfavorable. After dividing the stricture I noticed some improvement in the color of the bowel, and I put it back with some misgivings. The patient has progressed satisfactorily without rise in temperature.

Another point that I have observed is that in cases where omentum is present in the hernial sac and prolonged taxis has been employed, the bowel is not in as bad condition as where omentum is not present. I think that the presence of omentum may save the bowel from pressure.

A point which Dr. Ashhurst did not bring out, although I know that he is perfectly familiar with it, is the relative rapidity of the occurrence of dangerous strangulation in inguinal and in femoral hernia. In femoral hernia the strangulation is more dangerous in the same time than in inguinal hernia.

DR. RICHARD H. HARTE: I would ask Dr. Ashhurst's experience with Littre's hernia. I have seen two cases. One was brought to St. Mary's Hospital after prolonged taxis, and the hernia was supposed to have been reduced. The symptoms did not subside, and when I saw the case the man was dying. At the autopsy it was found that a small portion of bowel had been caught and was strangulated. The second case was seen at the Episcopal Hospital. In this case, too, operation revealed a small portion of the bowel which was caught and strangulated. These cases are apt to be overlooked until rather late symptoms of strangulation make their appearance.

DR. J. M. BARTON: In reply to the question of Dr. Allis, I have had six cases of umbilical hernia and have had the misfortune to lose two. A method of reduction that I have found successful, I think it is worth alluding to. In these cases, the strangulated bowel is invariably in the centre of a mass of omentum. The small knuckle of intestine is at the very base, and any pressure on the surface would be utterly useless. In a case of this kind, seen some time ago, I grasped the abdomen above and below the hernia and lifted the abdominal walls, actually raising the patient from the bed. At the second attempt this proved successful. I have employed the same method in another case with success.

I have had the misfortune to operate by Tait's method within a few weeks. The patient was a woman fifty years of age with well marked symptoms of obstruction. I examined all the openings, but did not find any hernia. I then made an abdominal section and found a small knuckle of bowel in the femoral opening. The extent of bowel caught was not more than three-fourths of an inch. The patient was quite fat, and in order to release it I had to prolong the incision over to the right side. The bowel was gangrenous, and in delivering it infection probably took place, the woman dying forty-eight hours later. There were no marked symptoms of peritonitis. For hernia I should not consider this operation for an instant, but I did not know the case was one of hernia. After delivering the intestine I put my finger in the femoral opening, and tried to feel it from the outside, but was unable to, owing to the amount of tissue over the femoral opening and the small size of the hernial sac.

DR. JAMES COLLINS: I have nothing to add except to mention a little manœuvre which sometimes succeeds after taxis has failed, and that is to put the shoulders on the floor and draw the hips up, making taxis in this position.

The youngest case on which I have operated was a child two years old. It got well. My oldest case was eighty-two years old. I have operated on a number of cases with success, with the exception of a few operated on at the German Hospital. In these cases the strangulation had existed for several days. I would emphasize the necessity of opening the sac. In one case where I opened the intestine, I found on drawing down the bowel, another band about the intestine. I have seen the same thing in other cases.

DR. WILLIAM G. PORTER: I would emphasize the point made by Dr. Collins as to the necessity of drawing down the bowel. I have seen two cases where the bowel in the sac was carefully examined and found all right and returned, and was immediately followed by a gush of liquid fecos. My explanation of these cases is that the strangulated portion had returned and a healthy portion of the bowel had come down.

DR. SAMUEL ASHHURST: I have seen a case like those referred to by Dr. Harte, and this prejudiced me against the oper-

ation without opening the sac. Taxis was employed and the tumor was reduced, but the symptoms did not disappear. The patient died, and at the post-mortem there was found a small portion of bowel still remained within the internal ring, not involving the whole lumen.

My experience has been that almost every case of hernia stands by itself. I do not think that I have seen a case which did not present peculiar features. It is this that makes hernia to me one of the most interesting subjects in surgery.

DR. THOMAS R. NEILSON: The question whether or not the strangulated bowel shall be returned is a very important and often perplexing one. I have several times been in doubt, but in all cases have returned the bowel after relieving the constriction, drawing down the bowel and searching for perforations, and noting that under bathing with hot water the color of the bowel slowly returns. Another guide is the preservation of the lustre of the peritoneal surface of the bowel. If the lustre is still present it is an evidence that the vitality is not entirely destroyed.

I have had two cases of Littre's hernia or partial strangulation of the bowel. One was in an elderly woman brought to the hospital after five days of the so-called obstruction of the bowel. The patient was practically moribund, but at the earnest solicitation of the patient I operated. The constriction was found at the internal abdomial ring, involving only a portion of the gut. The patient died shortly after the operation. The second case was in a young man with left inguinal hernia. The patient presented a tumor not larger than a large marble, exceedingly tender, with pain at the umbilicus and a tendency to nausea. I operated and found a Littre hernia of the small intestine, and the patient recovered. The possibility of the occurrence of this hernia should not be overlooked.

DR. J. EWING MEARS: I can report one case of umbilical hernia in which strangulation had existed for forty-eight hours and general peritonitis had supervened. I operated and made an artificial anus, but the patient died within twelve hours.

DR. O. H. ALLIS: I think the operation in umbilical hernia is no more dangerous than in femoral or inguinal hernia. Where the constriction has been prolonged, probably any form of hernia means death. From what I have seen of umbilical hernia, I maintain that if it is a favorable case it is as likely to get well as a case of femoral or inguinal hernia.

DR. JOHN ASHHURST, JR.: I think that Dr. Deaver is entirely correct in saying that in the majority of cases of strangulated hernia it is not proper to make an anastomosis of the bowel at the time of the herniotomy. Whether we should open the gut or resect a portion of it when gangrene is present, I think should be decided by the extent of the gangrene. If there is only a patch, it is sufficient to open the bowel; if a large portion is gangrenous, it is probably safer to remove it. In the majority of cases it is proper only to establish a false anus, which may be subsequently dealt with. The only exception is where the surgeon has reason to fear that the portion of bowel involved is high up in the small intestine, when so much of the bowel would be cut off from exercising its digestive function that patient would die of inanition, even if he should survive the immediate results of the operation. Under such circumstances, if the patient is in a condition to justify further interference, I think it better to complete the operation by uniting the bowel according to one of the methods suggested. In the case in which I removed twelve inches of the bowel and united the ends by circular enterorrhaphy, no extravasation occurred, and the patient's death did not appear to be due to the operation.

With regard to taxis, I had intended to refer to the view of Mr. Jonathan Hutchinson, a surgeon for whose judgment I have the greatest respect. It will be remembered that he has recently, in connection with the advocacy of abdomial taxis, as he calls it, in cases of intestinal obstruction, referred to the operation of herniotomy, and has maintained that the statistics of the London hospitals show that the operation is a very dangerous one. Therefore he urges a persistent and systematic resort to taxis. There is no doubt that a surgeon who approaches a case believing that it is never necessary to operate will be more likely to succeed by taxis than one who entertains the view held by many at the present time, that

taxis is almost certain to fail, and that it is therefore better to resort at once to herniotomy. The personal equation thus comes into these cases. In connection with this matter I should like to refer to a case which I recently saw at the Pennsylvania Hospital. An old man, extremely deaf and extremely obstinate, was brought to the hospital with a hernia that could not be reduced. The resident physician made a reasonable application of taxis, and failed. Then he put him under treatment with rest, cold and opium, and sent for me. I attempted taxis and failed. The patient positively refused to take ether or to submit to an operation. I then made another trial of taxis, pushing it further than I have ever done before and further than I liked to, and the hernia did at last go up, and the man went out happy the next morning.

As I said before, I have only once operated in umbilical hernia, and in that instance the patient died. It is seldom that operation is required in these cases, taxis almost always being successful. I think that the results of experience show that operation in umbilical hernia is more dangerous than in either inguinal or femoral hernia. I was interested by Dr. Barton's suggestion to aid the taxis in umbilical hernia by lifting the abdomial wall. The same object has been accomplished by Froumüller by applying an exhausted cupping-glass over the hernia, and Dr. Washington has recommended a similar procedure.

Dr. Wharton has referred to the state of the bowel. My rule is to pay a good deal of attention to its color, and I resort to the use of hot water to see if the color returns. The glossiness of the bowel is also of importance. If the bowel retains its natural lustre, it is usually safe to reduce it. If it is dull and lustreless, and still more if the tissues separate under the surgeon's finger, it is not safe to return it.

Reference has been made to the presence of omentum acting as a safeguard against injury to the bowel from taxis. The same thing is found where the sac contains serum. It was a clinical observation of the late Professor Joseph Pancoast that, when he opened a hernial sac and found a quantity of bloody serum, he felt that the patient was going to do well. In such cases the serum serves as a cushion to prevent damage to the hernia from the taxis.

Dr. Collins has referred to taxis with inversion. Before the days of anæsthesia this method was regarded as of great value, but, like other "adjuvants to the taxis," is, I think, now seldom resorted to.

Dr. Porter has spoken of the gush of feces that occurs sometimes when the bowel is reduced. This, I believe, is due to the sudden "letting on," as it were, of the peristaltic stream, rupture occurring at the sulcus which marks the point of constriction. In all cases, therefore, it is important to make a thorough examination of the bowel, and, if a sulcus is found, not to effect reduction of the part which has been constricted.

Reference has been made to the persistence of symptoms after reduction. In such cases, I think that it is the generally recognized rule that the sac should be opened and an attempt made to bring the hernia down again. If this cannot be done, it would be right to extend the incision upward, which I think would be safer than making a median section. The same rule applies where there are symptoms of strangulation and a hernial sac is, on exploration, found empty.

Dr. Harte and Dr. Neilson have both referred to strangulation of a portion of the calibre of the bowel, often spoken of as Littre's hernia, but more accurately designated as Richter's, Littre's being a hernia of one of the natural diverticula of the gut. These cases are apt to be overlooked, and abdominal section for these partial herniæ has therefore been resorted to, the same operation having also been practised for obturator hernia. In some cases it is impossible to recognize the existence of a hernia, and under such circumstances abdominal section might properly be employed; but where hernia in any particular position is suspected, I think that it will be advisable to open and explore at this position, rather than to begin with abdominal section.

Dr. Wharton has spoken also of the relative dangers of delay in femoral and in inguinal hernia. Femoral hernia will not bear temporizing, and taxis should not be tried with the same persistence as in inguinal hernia.

Dr. Wharton presented

A REPORT OF NINE CASES OF CONTUSIONS AND SPRAINS OF THE BACK, WITH SPECIAL REFERENCE TO THE TREATMENT OF THESE INJURIES.

(See page 879.)

DISCUSSION.

DR. JAMES COLLINS: I regard the method described as ideal with one exception. My habit has been to suspend the patient and then fix the back, not necessarily to lift him up, but simply to make the back straight. I regard this as necessary to make the treatment ideal.

DR. JOHN ASHHURST, JR.: I have often resorted to this mode of treatment. Where the condition is one of contusion rather than of sprain, I commonly apply lead-water and laudanum, or some similar fomentation, until the superficial tenderness has passed away, and then apply strapping. In sprain or partial rupture of the muscles of the back, the immediate application of straps or of some other means of securing complete rest is all that is required, but where there is a positive contusion there is, I think, advantage in first using anodyne fomentations for a few days.

DR. RICHARD T. HARTE: I have seen many contusions of the back at the Pennsylvania Hospital, the force often being received over the ribs and transmitted to the vertebræ. In these cases I think that there is a certain amount of synovitis and arthritis between the end of the ribs and the vertebræ. In all these cases treatment by strapping gave immediate relief. If the patients are allowed to go without treatment they often go from bad to worse and have a long convalescence.

DR. JOSEPH HEARN: It might be of interest to refer to the diagnosis between lumbago and sprain in the back. If a person sprains his back he goes about his work for an hour or two without any discomfort, but when he takes a rest he cannot get up. In lumbago the pain comes on suddenly and continues.

DR. WHARTON: I have had no experience with suspension, as I have been satisfied with the use of straps.

In cases where there was contusion with effusion of blood I formerly used lead-water and chloride of ammonium lotion, but in my recent cases I have resorted to strapping, even when this condition existed. In these cases the patients experienced relief, and the pressure probably limited the effusion of blood.

---

BRAIN TUMOR, PROBABLY TUBERCULAR IN CHARACTER, IN A CHILD SEVEN YEARS OF AGE, TREATED WITH LARGE DOSES OF IODIDE OF POTASSIUM — 103 GRAINS GIVEN DAILY FOR A PERIOD OF THREE MONTHS, WITH MARKED IMPROVEMENT IN ALL OF THE SYMPTOMS.

DR. J. EWING MEARS presented a patient for examination whom he had seen in consultation with Dr. Charles A. Groff. The patient, aged seven years, exhibited the symptoms of a brain tumor which was thought might be operable. Eye-examination by Dr. Oliver confirmed the diagnosis, but located the tumor in the posterior portion of the base of the brain. In view of the result obtained by this examination, it was deemed advisable to try the curative effects of large doses of iodide of potassium, given in gradually increasing quantities; 103 grains daily were finally administered with decided amelioration of the symptoms and without any ill effects from the use of the drug.

The history of the case is given by Dr. Groff as follows:

Elsie E., aged seven years. First came under observation in December, 1892. Complaining of severe headaches, happening almost daily and lasting for hours, during which the child was compelled to lie down until sleep came to her relief, apparently as the result of exhaustion. This had existed for two years, gradually becoming worse.

*Family history:* Father, painter by trade, was never sick in his life, never had syphilis, mother strong and healthy; no knowledge of having been sick.

There is a younger child, now less than two years old, born with equina varus, which difficulty has been almost entirely corrected by the use of splints and bandages.

Examination of patient at the date mentioned developed at once defective vision and slight paralysis of the right side, especially of the lower extremity. She was put upon bromide of potassium and was sent to an ophthalmic surgeon, who treated her for some time, but no

improvement in vision was noted, nor were the headaches lessened. She was sent to a second ophthalmic surgeon, who diagnosed a brain-tumor and said that nothing could be done for her.

In February, 1893, she was put upon iodide of potassium, six grains daily, which was gradually increased until August, when she was taking thirty-three grains daily. At this time the headaches had lessened in frequency, the condition of paralysis remained stationary, but the difficulty in vision seemed to be increasing.

Dr. Mears saw the patient on August 7th, in consultation. He agreed with me in the diagnosis, also in the treatment, and advised the increase of the iodide of potassium. This was done, ten grains being added to the daily dose every two weeks, until the child was taking one hundred and three grains daily. This point was reached in November, 1893, and was continued until February, 1894, when the amount was decreased to ninety grains daily, which quantity she has been taking up to the present time. As the remedy was increased, there was evident improvement in the condition of the patient. The headaches were much lighter in character and happening with markedly increasing intervals, until now they have practically ceased. The paralysis is much less marked, and Dr. Chas. A. Oliver, who has made repeated examinations, says her vision is improving.

Appended is the report of Dr. Oliver showing changes occurring under the administration of the large doses of iodide of potassium.

*Opthalmic examination, September 26, 1893.* Neuro-retinitis of a soft œdematous type, the left nerve-head being the more swollen; both the retinal arteries and the veins reduced in size, especially the latter; the left iris fails to respond to the strongest light stimulus; the right iris seems to respond at times; vision of right eye reduced to a doubtful light-perception in all portions of a considerably contracted field; vision in the left eye still further reduced to a faint recognition of light from the temporal side. These ocular conditions, with a general history of the child, gave a diagnosis of brain-tumor with enlargement of the ventricles; the supposed neoplasm being probably tubercular in character and situated in the posterior portion of the base of the brain (cerebellar?).

On October 18, 1893, there appeared to develop a doubtful left homonymous hemianopsia; the nerve-heads shrinking. No tubercular deposits could be recognized in any part of the fundus of either eye.

The irides gradually and interchangeably bettered in their reactions, the fields of light perception obtained both subjectively by the patient's recognition of the position of the light and at times objectively by the movement of the irides, until at the present writing they seem to respond much more freely than when the patient was first seen. Vision, which is reduced to perception of light, varies extremely upon different examinations, though relatively it is slightly better than when the patient was first seen; the examination at the last visit reversing the comparative areas of recognition in the right and left fields. Ophthalmoscopically, the nerve-heads are considerably shrunken and have become markedly atrophic.

---

## A Rare Case of Incarcerated Umbilical Hernia.

A. Ciechomski reports that a patient, æt. 58; female; suffering from symptoms of incarceration for seven days; During this time the patient and family had repeatedly refused the operation which he had advised. At the end of this period contrary to his expectation, the incarcerated loop slipped back into the abdomen, aided no doubt by an accidental fall out of the bed, there was an immediate amelioration of the symptoms as also an arrest of the secundary symptoms of sceptic peritonitis. Fourteen days later however, acute perionitis set in, which ended fatally.—*Gazette Lekarska* 1893, No. 47.) — Translated by M. B. Werner, M. D.

---

### Diphtheria and Membranous Croup.

The formula recommended by Dr. James R. Leaming is:—

℞

| | |
|---|---|
| Ammon. muriat. | ʒiij. |
| Potass. chlorat. | ʒj. |
| Aq. cinnamomi | ʒij. |
| Syr. acaciæ | ʒij. |
| Syr. senegæ | ʒj. |

M. Sig. Give one teaspoonful every five minutes until there is relief, or until vomiting ensues.

—*Prescription.*

# CURRENT LITERATURE REVIEWED.

IN CHARGE OF ELLISTON J. MORRIS, M. D., AND SAMUEL M. WILSON, M. D.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES for June contains a paper by Dr. Edward L. Keyes on

**Nephritis in its Surgical Aspects.**

The author sees no use in sterilizing or borating glycerine or vaseline as the results of some experiments instituted by him show that these will keep for years without becoming the lodging place of bacteria of any kind except the harmless air species. In regard to the constant use of the catheter in the prostatic enlargement of old men the author finds that the following rules have served him best. "A rubber catheter is kept constantly in a 1 in 4000 bichloride solution and washed in very hot water after each use. Simple glycerine is the lubricant. The anterior urethra is to be flushed as the catheter enters for the first time, and all the way in through the membranous and prostatic urethra, with a 1 in 4000 bichloride solution. The urine is to be entirely but very slowly drawn off (watching the pulse), the patient being recumbent. The bladder is then to be immediately washed out with a 1 in 1500 (sometimes 1 in 2000, if the stronger causes too much pain) nitrate of silver solution, which usually occasions moderate tenesmus. The bladder may then be washed out with a six per cent. salt solution (heaping tablespoonful to the quart), this to be drawn off, and such quantity of a weaker salt solution (teaspoonful to the quart) introduced and left as the surgeon may think best."

"The clean catheter, taken out of its bichloride solution and rinsed in hot water, and the salt solution, are to be used as often as any catheter is called for—further urethral flushings being a matter of personal judgment—the nitrate of silver being repeated every one, two or three days." In this way, the author states, the catheter may be used as often as necessary without infecting the kidneys and often without the presence of pus in the urine, and this goes on till the tissues have becomed hardened, when a non-disinfected catheter may be used, if simply kept clean.

When an operation is required, pus is generally already present in the urine. The author's routine practice here is to flush out the bladder and entire urethra before the operation with a salicylic acid solution followed by a 1 in 3000 or 4000 bichloride solution (after the anæsthetic has been given), and to follow the operation by a flushing out with a nitrate of silver solution, 1 in 1000; finally, and in subsequent washings for cleanliness, using about a six per cent. solution of common salt in hot water, and such strengths of the mercuric or argentic solution as seem called for. The author states that he has discarded boric acid solutions and Thiersch's solution on account of the difficulty of prompt preparation and because he has found the salicylic acid solution just as effective. Included in the paper are elaborate tables showing the relative germicidal properties of various drugs used to disinfect the urine either by the mouth or locally.

As the result of his experience the author comes to the following conclusions:

1. Healthy urine is sterile.
2. Purulent urine is always microbic.
3. Microbic infection takes place from within the body by a number of methods in the course of disease; it is often brought about by instrumental manœuvres on the part of the surgeon.
4. A healthy organism and vigorous bladder may cope successfully with microbic invasion, and rid itself spontaneously, or with a little aid, of all damage arising therefrom—showing little or even no inflammatory response.
5. A suitable condition of the patient's soil is essential to the propagation and perpetuation of inflammatory phenomena upon the urinary tract—after microbic invasion.
6. This condition, intensified by traumatism and physical weakness, notably of the degenerative variety, is most intense when there is vesical distention with atony, and when the ureters are dilated and the kidneys involved in the changes incident to tension below—namely, atrophy and sclerosis above, with or without surface catarrh.
7. Under these circumstances surgical pyelonephritis is most likely to declare itself as a result of microbic infection from below (occasionally from above)—in the course of suppurative disease or after operative interference.
8. Asepsis, antisepsis, and sterilization of urine are ends to be aimed at in genito-urinary surgery—but, like all other greatest goods, not yet attained in perfection. Much, however, can be done by local means in a prophylactic and curative way, little by internal medication, and possibly as much, or more than by any other means, by flushing the urinary passages with natural mineral waters.

A somewhat similar paper is that by Dr. George M. Sternberg on

**The Bacteriology of Pyelonephritis.**

After detailing the results of a number of experiments and quotting the utterances of various observers, he gives as his opinion that we are justified in including that cystitis and ascending pyelonephritis are usually caused by micro-organisms introduced through the urethra into a bladder which is rendered susceptible to infection by mechanical violence or chemical irritation. And that the most frequent cause of such local infection is the bacillus coli communis, which is constantly present in the intestine and upon the external surface in the vicinity of the anus,

from whence it may easily be transported to the interior of the bladder by catheters, etc., used by the patients themselves or by their medical attendants. But there is no evidence that the bladder is reached by the direct invasion of this or other bacteria without mechanical assistance.

Dr. Henry M. Lyman contributes a paper on

**Gastro-enteric Rheumatism.**

The painful paroxysms are experienced when the stomach is empty, that is several hours after taking food. The location of the pain is generally abdominal, usually occupying the epigastrium or the hypochondrium, possessing all the characteristics of neuralgia affecting the gaglionic nervous system rather than the cerebro-spinal nerves of the body. Rheumatic gastro-enteralgia exhibits a marked tendency to alteration with the neuralgias and myalgias that occur in other nerve territories. In this respect it conforms to the rule that governs the exhibition of vague, wandering, neuro-muscular rheumatism. The author then goes on to give the different diagnosis between this affection and the various other conditions for which it may be mistaken.

In the treatment, like other casses of intense neuralgia, the severest cases may require the palliative exhibition of an opiate, though the more ordinary cases are more easily relieved. When the period of distress occurs three or four hours after the last meal, it may be promptly arrested in many cases, by a crust of bread or a glass of milk, or a cup of hot water. The patient must, however, be cautioned against reliance upon such measures alone, for they sometimes aid in effecting dilatation of the stomach. Slightly alkaline liquids, such as lime water, are useful. When the gastric juice contains an extraordinary amount of hydrochloric acid it may be necessary to give sodium bicarbonate in doses of twenty grains, three or four times a day. Still better, because more curative, is the use of sodium salicylate or salol when the stomach will not retain the salicylate. The author recommends the patient taking a half ounce or more of salad oil whenever the stomach is empty. This also relieves the constipation that is so constantly present, and by liquifying the bile renders its discharge more easy and certain. In cases of obstinate constipation it is desirable to employ laxatives that stimulate the excretion of bile. The chronic character of the disease renders necessary a resort to alteratives in many instances. Small doses of mercury three times a day; potassium iodide with colchicum, together with tonic doses of quinine or of elixir calsayæ, must be administered for many months. Sometimes a course of nitric acid or of the ammoniated tincture of guaiac is very beneficial. Occasional mercurial purges should not be neglected and flushing the colon with hot water is often a means of great relief. The careful regulation of the diet is of the utmost importance. Elderly patients who are thin and neurotic often get help from small quantities of brandy or whiskey after meals, but this remedy is not to be taken habitually as arthritic subjects are very intollerant of alcohol. Debilitated patients who are easily exhausted, and who crave food at short intervals, should have a nitrogenous diet, with very little saccharine and starchy food. When fats disagree, they should be eliminated from the dietary; but when they are digested, they exercise a beneficial influence. Frequent warm baths give good results. Alcohol, tobacco, tea and coffee must be forbidden, for they are not compatible with arthritism, because they retard the processes of oxidation that need acceleration in every way. Great fatigue of mind and body must also be avoided.

Dr. J. Burney Yeo contributes a paper on

**The Management of Fevers,**

and particularly of typhoid or enteric fever. The author accepts the bacterial origin of the disease, and believes that a modification in the therapeutic conceptions and indications of specific fevers is therefore demanded. He also regards the antagonism of the pyrogenic and other poisons produced within the body by the micro-organisms which gives rise to these fevers as the most essential therapeutic indication to be applied in their treatment. In other words he is in favor of the "antiseptic" or "antitoxic" treatment of fevers of the specific type.

In the present paper he contends that already the results of clinical observation give promise of fruitful conclusions in the direction of obtaining effective agents for antagonizing the morbid activities of the infective or specific fevers, and that the average course and characteristics of such fevers can be favorably modified and controlled by such antagonists. As his experience widens he becomes more and more convinced of the practical values of such measures and of the practical necessity of continuing to work in this direction, so that we may improve upon our present resources, or develop them in greater perfection.

The author states that he has long been impressed with the great efficacy of a mixture known as euchlorine, and containing free chlorine, as obtained by the action of strong hydrochloric acid on powdered potassium chlorate. The mixture used by the author is made as follows: "Into a twelve ounce bottle put thirty grains of powdered potassic chlorate, and pour on this sixty minims of strong hydrochloric acid. A greenish-yellow gas is at once liberated. Close the bottle with a cork and agitate the mixture gently till the bottle is filled with the gas, then pour water into the bottle, little by little, closing the bottle and well shaking, at each addition, until the bottle is filled." Several antiseptics are here present in solution and therefore readily absorbable; free chlorine, hydrochloric acid, potassium chlorate, and probably one or two by-products. In twelve ounces of this solution he causes twenty-four to thirty-six grains of quinine to be dissolved, and some syrup of orange-peel added to make it more agreeable to take; and of this, in adults, he orders one ounce to be given every two,

three or four hours, according to the severity of the case. He has adopted this method of treatment in all cases of enteric fever with uniformly good results.

The effects of this treatment, according to the author, are:

1. There is a remarkable cleaning of the tongue and mouth. The aspect of the tongue in cases so treated is frequently quite unlike the usual tongue of enteric fever.

2. The foul, putrefactive odor of the feces is quite rapidly removed if the remedy be given sufficiently often and in sufficient quantity, for this fluid and perfectly soluble antiseptic certainly reaches and passes through the small intestine, as the nurses constantly report the odor of chlorine in the evacuations.

3. Another important effect of this treatment is a sustained depression of the febrile temperature—a continuously favorable effect on the pyrexia. The pyrogenic toxine seems to be under control, or continuosly neutralized, or excreted.

4. In certain cases, especially in young subjects, and if the treatment has been begun quite early in the case, the average course of the fever appears to be notably shortened.

5. There is another very striking effect of this treatment, and that is that the patients seem subjectively so much less disturbed by the fever poison. Their physical strength and intellectual clearness are far better maintained than by any other method of treatment that the author is acquainted with. In many cases the nervous system shows none of the signs of febrile intoxication that are so commonly seen. Finally, their convalescence is more rapid and complete, and troublesome squellæ, so far as the author's experience goes, are unknown.

The author states that the effect on the temperature is slowly developed, and it may take forty-eight hours before any notable effect on the temperature is produced. The temperature may actually rise a degree, or even more, in the first twenty-four hours of its administration, which appears to the author to indicate that the antipyretic effect is due to a general antagonizing influence on the pyrogenic poison in the tissues, rather than from any immediate or direct effect on the heat-regulating mechanism.

The author is of the opinion that nourishment in typhoid fever should be administered very dilute and only in such quantities as the patient can absorb. As to the use of stimulants, he believes that the general tendency is to give them too early and in too large quantity. They are needed, in moderation, toward the end of the most severe and protracted cases, but the less severe cases do better, in his opinion, without any. He has used, in association with moderate amounts of alcohol, in protracted cases with marked cardiac debility, infusion of coffee, with more marked and sustained stimulation of the heart than when alcohol alone has been given. He thinks those excellent cardiac stimulants, tea and coffee, have been too much neglected in the treatment of fevers.

The author is opposed to the use of the depressing antipyretics, and regards the cold bath as attacking a result of the disease only. He states that he has seen calamitous results follow its use, and as a routine treatment he emphatically condemns it.

**Apoplexy in its Relations to the Temperature of the Body,**

With a consideration of the qnestion of heatcedtres, is the title of a paper by Charles L. Dana, M. D. The following is a summary of the results reached by him:

1. That all intra-cranial hemorrhages, whatever their lesion, are much more apt to be accompanied with immediate disturbances of temperature than are necrotic processes from embolism and thrombosis. These temperature disturbances in hemorrhages are, in rare cases, a sudden initial fall, then, in almost all cases, except where the lesion is small, there is, within a day or two, a rise of temperature of from one to three degrees. On the other hand, in acute softening, this initial fall and early rise do not occur unless the process is very extensive or involves the pons.

2. In apoplexy due to hemorrhage, the temperature is greater upon the paralyzed side than on the normal, the difference averaging one degree. In acute softening, this unilateral difference of temperature does not occur, or is extremely slight.

3. The rise of temperature due to apoplectic lesions depends more upon the extent and nature of the lesion than upon its location. Lesions of a hemorrhagic character in the cortex, however, are especially apt to cause a rise of temperature. Lesions in the pons, also, either of hemorrhagic or softening character, almost uniformly cause a rise of temperature.

4. There is as yet no clinical evidence that lesions of the basal ganglia or the parts about them cause temperature rises on account of destruction of certain thermic centres; in other words, the clinical and pathological evidence of thermic centres in the human brain, aside from the parts mentioned, is yet inadequate.

The author urges the importance of a careful study of apoplectic cases in regard to the temperature changes. The temperature should be taken on both sides of the body and in the rectum if possible. With data thus gained one can, he feels sure, obtain much more positive evidence as to the nature of the lesion in these cases, and the author has repeatedly been able to satisfy himself, in his clinical work, of the nature of the lesions by means of the methods referred to. He does not believe that, with the help of the numerous factors which we now have in aiding our diagnosis, there are many cases of apoplexy in which it is difficult to make a diagnosis. The old time tabulation of differential points in diagnosis between hemorrhage and acute softening are valuable.

**The Abuse of Trachelorrhaphy**

is discussed by Dr. William R. Pryor in an able article. The question of the immediate closure of the cervix is not entered into in

the paper, which deals solely with the secondary operation. The author condemns those gynecologists who sew up the cervix in a nullipara for the same reason in both—the cure of sterility. In the one case the cervix is too stenosed, they say, and therefore the woman is sterile; in the other it is too open, and again she is sterile.

Retarded involution seems to him the result of other causes than a torn cervix and he is more inclined to attribute it to a protracted first stage of labor with the consequent fatigue of the uterine muscle, together with a poor general condition. Cystic degeneration of the cervix more frequently follows as the result of generous tears and the possibility of its occurrence is perhaps some slight argument in favor of the immediate operation. But its presence is a positive contra-indication to trachelorrhaphy. The most profound questions in connection with the histogenesis of epithelioma are suggested by these cases. They demand a very thorough removal of all the affected tissue, and not puncturing the cysts and trachelorrhaphy.

The author expresses his belief that in the effects of lacerated cervix, except to a very limited degree. In some women any form of peripheral irritation will establish a more or less severe degree of neuritis; and occasionally a cystic cervix will have such an effect. The removal of the affected tissue is here demanded and not its union by suture.

The author believes that cancer of the uterus is becoming more and more frequent, but he rejects the teaching that laceration of the cervix is the cause, and believes that the phenomena of development and involution incident to pregnancy are much more prominent in the causation of cervical cancer than are the tears which invariable follow labor. The great part which functional activity with periods of repose plays in causing cancer is well shown in the preponderance of mammary cancers in those women who have nursed. Women who have by heredity a tendency to cancer should remain sterile, inasmuch as repeated childbirths more than anything else conduce to it and disseminate it. If we operate to *prevent* the possible occurrence of cancer in those who may reasonably expect it, assuredly trachelorrhaphy is not indicated, but a more radical procedure which will remove the entire cervix.

A pathological laceration of the cervix, requiring trachelorraphy, he would define as any laceration which is of such severity and degree as to implicate the circular fibres of the cervix sufficiently to cause a modification in the shape or position of the uterus. A tear to do this must sever most of the sphincter fibres of the cervix at one or more points. The lesions found associated with the laceration of the cervix he deems best treated by either a currettage of the uterus or by some form of amputation of the cervix which provides for the maintenance of a cervical mucous membrane. And usually it is well to combine the two operations in conditions demanding the latter.

Trachelorraphy he would limit to the immediate operation for hemorrhage, and to those cases of tear through the cervix from internal os out to the vaginal junction, cases of true extra-peritoneal rupture of the uterus.

The great objections that he has to trachelorrhaphy are, that it does not give a cervical canal of dimensions equal to the requirements of a woman, who should, as she gets older, bear each successive child with greater ease and security than the preceding; it does not remove sufficient tissue where operation is indicated; and it does not appeal to him as a rational procedure, believing, as he does, that most of the cases subjected to it require no operation whatever on the cervix, inasmuch as a generous laceration is normal and necessary.

Dr. Florian Krug advocates

**Hysterectomy in Bilateral Disease of the Appendages**

for the following reasons:

The uterus without the adnexa is a useless organ, and devoid of physiological function.

It is not innocuous; it is, on the contrary, positively a diseased and therefore harmful organ.

Histologically, the tubes are but parts of the uterus, and their removal is partial amputation of the uterus; therefore, why should we not go a step further and remove the rest of the diseased organ?

Careful observation and questioning of his patients, he states, has elicited the fact that the artificial menopause is much easier for a woman who has had her uterus removed, whether for cancer, for fibroid, or when associated with disease of the adnexa, than when the tubes alone were removed. The explanation of this lies in the fact that when we remove the uterus we remove the great mass of ganglionic tissue in the organ. So far from increasing the mortality, he states that the mortality is lessened in the hands of those familiar with the technique of hysterectomy. In its performance it takes no longer than the admittedly proper procedure of curettage preceding a celiotomy, and some less than to attach a proper drain where drainage is demanded, or to do a hysterorraphy.

Dr. W. W. Keen contributes a paper on

**Amputation of the Entire Upper Extremity**

(including the scapula and clavicle) and of the arm at the shoulder-joint. The paper has a special reference to methods of controlling hemorrhage. The author reports on one case of the former and amputation and four of the latter. After detailing the various methods in use for controlling the vessels during the operation, the author states that he has adopted the following method, which may be called Weyth's method, as it is essentially an application of his hip-joint method to the shoulder. With the patient at the edge of the table with his arm held at right angles to the body, two sharp-pointed cylindrical pins eleven inches long and one-quarter of an inch in diameter near the head, are used. The anterior pin is introduced through the middle of the anterior axillary fold, (tendon of the pectoralis major) at a point a little nearer to the body than what may be called the centre of the fold transversely. The point of emerg-

ence of the pin is of much greater importance than the point of insertion; this should be an inch within the tip of the acromion. The point of the pin is protected, after being pushed through, with a piece of sterilized cork. The second pin is now introduced at a corresponding point through the posterior axillary fold (tendon of latissimus dorsi), emerging again an inch within the tip of the acromion. Some little care is needed to avoid striking the spine or the scapula. The exact point of emergence is important in order to avoid the objection that, if the pin emerges near or at the tip of the acromion, the moment the head of the humerus is removed the tubing is apt to slip downward, compress the two flaps against each other, and thus hide the cavity formerly occupied by the head of the humerus. The vessels may then retract and bleed freely in this cavity, and, being entirely inaccessible except by removal of the apparatus, will require ligation of the subclavian, or, if the tubing is removed, copious hemorrhage will follow before the vessel can be caught. The pins being placed in position, a piece of black-rubber tubing half an inch in diameter is then wound tightly around the axilla and shoulder on the hither side of the pins. It is important that this tubing should be the pure black rubber, which is very elastic, and not the far less elastic white-rubber tubing. The disarticulation having been completed, the main vessels and all other visible smaller vessels are tied and the tubing quickly removed. All other spurting vessels are then seized with hemostatic forceps. The author states that he has not troubled to remove the pins until after seizing the vessels, so little have they been in the way. The puncture made by the pins heals quickly, and is of absolutely no importance. The only object of the pins is to hold the tubing in place and keep it from slipping. The author feels quite confident that any one who will adopt the method in the manner described will abandon definitely all other methods in favor of this, except in emergencies, which, of course, are subject to no fixed rules.

For the control of hemorrhage in cases in which it is necessary to remove the arm, the scapula and the clavicle, the author advises that the subclavian vein and artery be tied, previous to amputation, by resection of the clavicle at its middle portion.

In amputation at the shoulder joint, in cases where the axilla is invaded so high that Wyeth pins cannot be used, the author follows the method of Delpech, which consists in making an oblique incision extending from the external third of the clavicle to an inch above the inferior border of the great pectoral muscle. The lesser pectoral can then be cut near to its origin on the coracoid process of the scapula. The index finger is then carried through the cellular tissue along the serratus magnus muscle, then the subscapular, and is used as a hook in order to draw outward the mass of vessels and nerves. The artery is always situated at the anterior part of the mass, is surrounded, and, as it were, indicated by the roots of the median nerve, and nothing is easier than to surround it with a ligature which will embrace nothing else. This process is preferable in that it produces but little injury to the parts, that it leaves a certain space between the ligature and the trunk, and permits temporary compression of the subclavian artery, above the clavicle, on the first rib.

The article is illustrated by woodcuts and photographs illustrative of the procedures referred to by the author in his paper. Reports of cases are also given.

# PERISCOPE.

IN CHARGE OF WM. E. PARKE, A.M., M. D.

## GYNECOLOGY.

### Menstruation and Ovulation.

From a rather extended histologic study, Leopold and Mironoff conclude that menstruation, i. e., the periodic discharge of blood from the uterine mucous membrane, is usually accompanied by ovulation, although the former not rarely occurs without the latter. The hemorrhage depends upon the presence of the ovaries and an adequate degree of development of the uterine mucosa, and not upon the maturation and rupture of ovisacs. Ovulation occurs, as a rule, at the same time as menstruation. The process requires an increased afflux of blood to the generative organs for several days, and results in the formation of a typical corpus luteum. Ovulation may also occur independently of menstruation, though under physiologic conditions but rarely. At times ovulation, with the formation of a typical corpus luteum, is replaced by an afflux of blood to an ovisac that has not matured and does not undergo rupture, resulting in the formation of an atypical corpus luteum. Normal ovisacs may be present at a time when the ovaries are undergoing senile contraction, and they may undergo physiological rupture and form typical corpora lutea.

## MEDICINE.

### Note on the Treatment of Warts by the Internal Administration of Arsenic.

Symson contributes an article on this subject in the *Quarterly Medical Journal.*

Though warts sometimes disappear spontaneously without any treatment whatever, and, although the treatment of them by various kinds of outward applications is often perfectly successful, yet quite enough cases

are found apparently intractable by ordinary methods to justify a short note on the use of a drug which seems specially adapted to cure this tiresome and vexatious complaint.

First, a word or two as to local remedies. The writer has tried on different patients, and occasionally the same patients, nearly all the drugs usually recommended for the abolition of warts. Such are glacial acetic acid, salicylic colloid, fuming nitric acid, carbolic acid, liquor potassæ and argenti nitras. The first two named in this list seem to act best, and the salicylic colloid he prefers of the two, as most easily applied by any unskilled person and least irritating to the patient.

But for the last few years, acting on a suggestion in an American medical journal, and on account of Mr. Pullen's paper (*Practitioner*, 1888, vol. i, p. 207), in every case of warts which did not show some signs of yielding to these applications in ten days or a fortnight, he prescribes small doses of arsenic internally. Of its rapid action on the warts there can be no doubt whatever. He has repeatedly tried it by itself, and by the end of a fortnight even a large crop of warts will have disappeared. An advantage, also, of its use alone is that by children (who are, of course, the chief sufferers from warts) any kind of caustic or painful operation is much dreaded; also, very little arsenic need be given. The drug need not always be given as long as a fortnight, for a week's treatment by small doses, twice a day, seems to set up a healthy action in the warts, which is continued after the medicine has been left off. The combined treatment, though, of arsenic internally, with salicylic colloid painted daily on the wart, is quicker than that by arsenic alone. The author gives one, two or three minims, either of the liquor arsenicalis or liq. arsenici hydrochlor., twice or three times a day, according to the age of the child, and has never found it needful to exceed the largest dose. He has never found any symptoms of its disagreeing with the patients.

Its action on the warty growth is no doubt due to the increased metabolism of the skin, leading to these hypertrophied portions being killed and exfoliated.

---

### Muscular Rheumatism.

The following abstract in the *British Medical Journal* of an article by Leube is from the *Deutsche med. Woch.* in which he argues that muscular rheumatism is not a local disease, but a general infective disorder with special localizations in the muscular system. The mode of onset of the disorder varies, but is sometimes marked by shivering and prodromal fever, and by *malaise* of some duration. In some cases the muscular pains may be widespread, and occasionally endocarditis is observed. Taking a series of about 200 cases, he found that fever was present in about one-third; it was seldom higher than 102° F., and generally fell after two days in hospital either rapidly or after some irregular fluctuations. In one-sixth of the cases there was a cardiac murmur at the time of admission; it is generally supposed that endocarditis, which is so common a "complication" of joint rheumatism, scarcely ever occurs in relation with muscular rheumatism. It is not possible to say in how many of the cases in which a murmur was observed this was present before the onset of the muscular rheumatism, but it was noticed that in half the cases the murmur grew fainter or disappeared while the patient was under treatment, and that whereas in all the cases together fever was observed in one-third only, it was present in two-thirds of those in which there was a murmur. Moreover, in a few cases the murmur was observed to appear after the onset of the muscular rheumatism. Three such cases are related by Leube, but in one there was at a later stage muscular rheumatism, and in another the patient at the time the muscular rheumatism came on, was under treatment for gonorrheal urethritis, vaginitis, and cervical endometritis. Leube states that he has seen joint rheumatism come on after muscular rheumatism in several cases, and points out that muscular rheumatism is frequently observed after affection of the joints. Pleurisy was in a few rare cases observed as a complication of muscular rheumatism, but albuminuria only once. Leube concludes that it is highly probable that the infective material in muscular rheumatism is an attenuated form of the virus of acute rheumatic arthritis. In Wurzburg, where his observations were made, the cases of muscular rheumatism coming on at the clinic were, as a rule, few in number and isolated, but at one time recently a large number of cases applied, so that half a ward was filled with them; this would appear to indicate an epidemic influence. He only mentions the question of treatment incidentally, but would seem to have relied on salicylate of soda.—*N. A. Practimis.*

---

### Special Exercise to Correct and Prevent Constipation.

Friction, rubbing or massage over all parts of the abdomen two or three times per day by the patient himself, or less frequently by a good magnetic operator, will help to promote vital action of the bowels. If not convenient for the patient to walk or ride for exercise, he can secure the advantage of both in large degree by the following exercise, taken in his room.

Standing with the feet well apart, to broaden your base, bend or flex the lower limbs at the knees and extend the same about twice a second, or one hundred times a minute, for several minutes at a time, three or four times a day, and at the same time twist or turn the body above the hips first to the right and then to the left as far as you well can, resting the hands upon the hips or allowing them to hang by your side. At each turn of the body toward the right or left you will bend the knees about three or four times. You thus use chiefly the flexors and extensors of the thighs and the rotating muscles of the trunk. The motion of the body is meanwhile up and down, and the

motion of the chest and head is alternately to the right and left. To facilitate the turning of the body, the heel of the limb opposite the one on which you rest, as the body sways from side to side, may be raised so as to allow the limb to turn upon the ball or toe of the foot. To get the best effect of this exercise, the head must be kept well up, the shoulders back and the spine erect during exercise. The bowels may generally be allowed to rise and fall with the body, but at times it is well to exercise the diaphragm by endeavoring to draw up beneath it the liver and viscera of the abdomen.—Dr. Dutton in *Jour. Amer. Health Society.*

### Rest in Heart Affections.

Dr. T. Lauder Brunton believes that as a remedial measure, rest frequently requires to be absolute; as a preventive one, it may be only relative. The amount enjoined must be carefully proportioned to each case, as in advanced mitral disease, when the power of the heart is failing, absolute rest gives satisfactory results, in that the circulation recovers its balance, the arteries become filled and the veins emptied, the dropsical effusion and venous engorgement of the organs disappear and the patient recovers a fair amount of health.

The philosophy of this is well known to medical men. In the early cases of valvular affections of the heart perfect rest may prevent the mischief extending, and, at least, will help the heart to recover itself. This is especially the case when there is any indication of heart disease in growing boys or anæmic girls.

In anæmic girls, however, gentle exercise is advisable, but it must be carefully graduated, as exhaustion is likely to do harm. Massage may be useful, as it gives the patient exercise without putting any strain upon the heart. With a fatty heart, gentle exercise may be advisable, as it may be more likely to bring about a healthy condition of the heart than absolute rest.

When in mitral disease cardiac tonics, even pushed to their utmost limit, fail to give relief, then absolute rest becomes of great importance. Massage is of great usefulness in clearing out the body-waste, quickening the flow of blood through the muscles and relieving the edena, and the patient gets the advantage of the exercise without overdoing his heart. It also allows the treatment to be carried out more easily than would otherwise be, for it removes the feeling of weariness and irritability, faintness and unrest of the patient.

## OBSTETRICS.

### Eleven Months Pregnancy.

Max Bensinger reports a case of eleven months pregnancy in a healthy woman 27 years of age, who had previously given birth to two children of normal weight and appearance, delivered at proper term. The child, a boy, was born alive after twelve hours labor without instrumental aid. He registered the abnormal weight of eleven pounds. The placenta was exceedingly large, and the amniotic fluid very scanty. This case has considerable interest from a medico-legal point of view, inasmuch as the courts in most countries accept 300 days as the extreme limit of pregnancy. If the husband of such a woman should happen to die during the first or second months of gestation it would not only blacken her reputation, but the child would be deprived of its rights of paternal inheritance, which might involve a large estate or even a crown. Hence the importance of physicians recording all cases of retarded pregnancy.—*Pacific Med. Jour.*

## ARMY AND NAVY.

### CHANGES IN THE U. S. ARMY FROM JUNE 3, 1894, to JUNE 9, 1894.

The following named officers, having been found by Army retiring boards incapacitated for active service on account of disability incident to the service, are by the direction of the President, retired from active service.

Lieutenant Colonel Samuel M. Hornton, Deputy Surgeon General.

Captain Marcus E. Taylor, Assistant Surgeon.

Captain William G. Spencer, Assistant Surgeon.

Upon being relieved from duty at Camp Merritt, Montana, by First Lieutenant William H. Wilson, Assistant Surgeon, First Lieutenant Edward L. Munson, Assistant Surgeon, will proceed without delay to Fort Yellowstone, Wyoming, and report to the commanding officer, for temporary duty with troops in the National Park during the season.

### U. S. MARINE HOSPITAL SERVICE FOR THE FIVE WEEKS ENDING MAY 26, 1894.

Murray, R. D., Surgeon; to proceed to Brunswick, Ga., for special duty April 30, 1894. To procced to Waynesville, Ga., as inspector, May 17, 1894.

Hutton, W. H. H., Surgeon; detailed for duty as Inspector of Quarantine Stations, April 27, 1894.

Hamilton, J. B., Surgeon; granted leave of absence for three days, May 14, 1894.

Gassaway, J. M., Surgeon; granted leave of absence for fifteen days, May 12, 1894. Leave of absence extended five days, May 26, 1894.

Stoner, G. W., Surgeon; to inspect Cape Charles Quarantine Station monthly, April 27, 1894. Granted leave of absence for thirty days May 18, 1894.

Godfrey, John, Surgeon; to represent the service at meeting of American Medical Association, at San Francisco, Cal., May 11, 1894.

Irwin, Fairfax, Surgeon; to proceed to Berlin, Germany, for special duty, May 5, 1894.

Carter, H. R., Surgeon; granted leave of absence for three days, May 3, 1894; to pro-

ceed to Key West Quarantine for temporary duty, May 4, 1894.

Banks, C. E., Past Assistant Surgeon; granted leave of absence for five days, May 1, 1894.

Carmichael, D. A., Past Assistant Surgeon; to proceed to St. Louis, Mo., for temporary duty, May 15, 1894.

Peekham, C. T., Past Assistant Surgeon; to proceed to San Francisco Quarantine Station for duty, May 17, 1894.

Glennan, A. H., Past Assistant Surgeon; to proceed to Wilmington, Del., for special temporary duty, April 25, 1894.

White, J. H., Past Assistant Surgeon; to inspect Quarantine Stations, April 29, 1894; granted leave of absence for seven days, April 29, 1894; granted leave of absence for twenty-three days, May 4, 1894.

Bratton, W. D., Past Assistant Surgeon; to report at Bureau, and then to proceed to Delaware Breakwater Quarantine for duty, May 19, 1894.

Magruder, G. M., Past Assistant Surgeon; to proceed to Key West Quarantine Station for duty, May 15, 1894.

Kinyoun, J. J., Past Assistant Surgeon; to proceed to Wilmington, Del., for special temporary duty, April 26, 1894; detailed as Chairman Board for physical examination officer, Revenue Marine Service, April 30, 1894; detailed to attend annual meeting State Board of Health, of North Carolina, May 11, 1894; to inspect property at Wilmington, N. C., May 14, 1894.

Woodward, R. M., Past Assistant Surgeon; to proceed to Chicago, Ill., for special duty, May 7, 1894.

Vaughn, G. T., Past Assistant Surgeon; detailed as Recorder Board for physical examination Officer Revenue Marine Service, April 30, 1894.

Stonel, J. B., Past Assistant Surgeon; to inspect Quarantine ports, April 26, 1894.

Perry, J. C., Past Assistant Surgeon; to assume command of service at Norfolk, Va., May 4, 1894.

Young, G. B., Assistant Surgeon; to proceed to Key West, Fla., for duty, May 15, 1894.

Brown, B. W., Assistant Surgeon; to proceed to Pittsburg, Pa., for duty, April 27, 1894.

Rosenau, M. J., Assistant Surgeon; to proceed to Boston, Mass., for duty, April 23, 1884.

Cofer, L. E., Assistant Surgeon; to proceed to San Diego, Cal., as Inspector, and to assume command of the service after June 30; April 26, 1894.

Eager, J. M., Assistant Surgeon; to proceed to New Orleans, La., for duty, May 16, 1894.

Nydegger, J. A., Assistant Surgeon; to proceed to Savannah, Ga., for duty, April 28, 1894.

Strayer, Edgar, Assistant Surgeon; to report for duty on Revenue Bark "Chase," April 28, 1894.

Oakley, J. H., Assistant Surgeon; to rejoin station San Francisco, California, May 16, 1894.

PROMOTIONS.

Assistant Surgeon G. B. Young, commissioned as Passed Assistant Surgeon, May 25, 1894.

Assistant Surgeon W. G. Stimpson, commissioned as Passed Assistant Surgeon, May 25, 1894.

APPOINTMENTS.

Arthur R. Thomas, of Illinois, commissioned as Assistant Surgeon, May 25, 1894.

Henry W. Wickes, of Maryland, commissioned as Assistant Surgeon, May 25, 1894.

Hugh S. Cumming, of Virginia, commissioned as Assistant Surgeon, May 25, 1894.

## NEWS AND MISCELLANY.

Dr. Emory Lamphear, for many years editor of the *Kansas City Medical Index*, has resigned the chair of Operative Surgery and Clinical Surgery in the Kansas City Medical College and has removed to St. Louis. He makes the change in order to become Professor of Surgery in the St. Louis College of Physicians and Surgeons, one of the oldest and strongest medical schools in the West.

Dr. C. D. Palmer, of Cincinnati, is receiving the congratulations of his many friends on the verdict in the malpractice suit against him, which was rendered in his favor May 26th inst.

In 1888 the doctor in making a perineal operation on a woman, broke his needle. Careful search failed to find the fragment either in the soft parts or on the floor. The patient was not doing well under the anesthetic and further search was deemed unwise and the operation brought to a finish. A few days after the doctor was thrown from his buggy in a runaway and received severe injuries about the head, remaining in an unconscious or semi-unconscious condition for about a month and being utterly unable for business for a year. In the meantime the patient fell into the hands of another physician who operated again and found the needle. The case was taken up by a couple of young lawyers whose time hung heavily on a contingent fee and fought desparately. The editor of the Cincinnati *Lancet-Clinic* used some strong language in regard to the young barristers in his journal. They went to his office with horsewhips and attempted to horsewhip the editor. They had miscalculated muscular force however and received the whipping themselves, after which they fled leaving their arms behind them. The editor went to the police court whips in hand and swore out a warrant for their arrest and had them fined for assault and battery. This aggravated the youths and made the fight more bitter. Dr. Palner is and has been professor of Gynecology in the Medical College of Ohio for a quarter of a century, and is on the staff of the Cincinnati and Presbyterian Hospitals. The doctor was ably defended by Judge Conner, brother of Dr. F. S. Connor. The amount sued was for $10,000. It has been one of the most malicious cases in court.

MEDICAL AND SURGICAL
REPORTER.

No. 1948. PHILADELPHIA, JUNE 30, 1894. Vol. LXX—No. 26

## ORIGINAL ARTICLES.

### OBSERVATIONS ON TYPHOID FEVER.

JOHN M. CURRIER, M. D., Newport, Vermont.

Having seen thirty-six years of the practice of medicine has led me to change some of my views of typhoid fever, not only of its etiology but also of its pathology and treatment. Mercury in any form I do not employ, and beef-tea, once so popular, contains almost no nourishment. Patients who were fed on it starved so that they could not be resuscitated. Cathartics I seldom have occasion to use, and, on the other hand, if there is diarrhœa, I do not check it unless there are more than three evacuations a day, or unless there is much pain accompanying them.

I am not a microscopist, but I accept the theory of the microbe as the cause of typhoid fever; that it is introduced into the system through the alimentary canal in the food and drinks. The mucous membranes of the stomach and intestines are the first organs affected; next the glands of the intestines. In these last named organs is located the seat of the pathognomonic symptoms of the disease. I shall dwell on this part of the pathology of the disease more particularly than on all others, on account of its bearing on the treatment, and of the importance in sustaining the patient.

We often hear that mild cases of typhoid fever result fatally, and very unexpectedly too. Many of these cases undoubtedly could have been saved if the treatment had been less irritating and more supporting in the early stages. These calamities are due to want of prompt and efficient feeding in the early stages. Patients are not hungry, and the attending physicians are not inclined to force nourishment, consequently the patients approach the point of death before any one suspects the danger.

If the stools of a typhoid fever patient be watched, the characteristic exudation of lymph from the inflamed surface of Peyer's patches and other affected glands will be discovered in them; usually if the stools are quite liquid, they will float upon the surface. These masses of lymph are irregular and flattish, varying in size from one-fourth to one inch in diameter. In consistence they resemble masses of recently exuded cherry gum. Early in the disease they are quite clear, but as the inflammation of the glands increases they may become streaked with blood, and in the latter stages of the disease exfoliated patches of the mucous membrane containing the entire glands may be seen. These glands are sometimes studded with clots of blood in their substance. This exudation will oftentimes enable the attending physician to determine the nature of his disease in mild or "walking" cases of typhoid fevers, which for many days may be involved in doubt.

There is one point I wish to touch upon in the physiology, pathology and treatment, upon which authors never, or seldom write, which I think is of great importance in this dreadful disease. I refer to the tendency of the entire circula-

tion in the portal system to become lethargic, both in health and disease, or greatly diminished, so that the digestive system during these periods of rest becomes almost bloodless. The intestines unless distended with food or gases become shrunken and very pale. This in health is a physiological process. The same tendency or function exists in typhoid fever, and then becomes a cause of pathological processes which result in disastrous consequences in the latter stages of the disease. The glands of the intestines are in a congested condition, and during these periods of rest or lethargy the blood in them becomes stasic, and on the return of the circulation to the portal system complete circulation is not re-established in the glands; they, consequently, become gangrenous and slough off. These sphacelated patches can be detected in the stools of the patient if watched for. If in these cases some of the large blood vessels are ulcerated and torn off, hemorrhage takes place and death may result from loss of blood. This is an important feature in typhoid fever, and one that the attending physician must from beginning to end have in view in the treatment adopted.

Biliousness or disordered liver complications in typhoid fever are not so numerous as authors lead us to believe. Undue importance has always been attached to the liver in all diseases, and typhoid fever is not exempt from the myth. Periodicity or engorgement of the liver takes place every time there is increased circulation in the portal system, for there is no other channel through which the blood can be returned to the general circulation and when there is increased vascularity there is increased functional activity. This periodicity of rest and returning engorgement is a healthy function of the organs of the portal system, and should be distinguished from the charges made against the liver, both by the profession and laity, as being "torpid." In the latter case it is assumed that the liver lies inactive, and that its function cannot be restored except by the use of physicians' drugs. This condition I shall dismiss as a "myth."

There is another point in the circulation of the digestive system upon which I wish to make some observations, that we seldom see treated very extensively in any work on physiology or pathology: that is the sectional engorgement of the various abdominal viscera. One portion of these organs may be very abundantly supplied with arterial blood while another section, a short distance away, may be almost bloodless. This condition of the circulation takes place in all normal or pathological states of the digestive system. The introduction of food into the stomach causes increased circulation in the stomach, while the intestines not engaged in the digestive process remain quiescent and almost bloodless. As the food passes along down the intestines they become engorged with blood, and the stomach in turn receives less blood supply as the food passes out of it. Likewise the upper portions of the intestines receive less blood supply as fast as the food passes along down and the process of digestion becomes completed. This same sectional engorgement takes place from any irritation other than digestion existing anywhere along the intestinal or digestive tract. This physiological process may be observed in every autopsy or laparotomy. In a recent case of diaphragmatic hernia the autopsy revealed a portion of the colon, omentum, and caput coli, nearly strangulated in the hernial sac and greatly congested, while the remaining organs were but slightly, or not at all, congested. This sectional and periodical engorgement and bloodlessness of the portal circulation has an important bearing upon the pathology of typhoid fever.

I shall offer only a few suggestions in the treatment of typhoid fever. Beef tea I do not give with the view of receiving any benefit from it; sometimes I allow it in cases where the patient desires it to please his palate, but then I am sure to give the usual amount of nourishment to keep up the strength of the patient. The blood plasma is impoverished by the typhoid poison; the patient grows weaker as a natural consequence; the appetite is wholly or in part lost; the patient is disinclined to take food, and unless the nutrition is made an important part of the treatment in the early stages, the patient may soon lose the chance of recovery.

Proper nutrition is more important than medication. Boiled milk, given cold or warm to suit the patient's taste, with or without some farinaceous gruels, with

sweet cream constitutes the principal food for my patients during the whole course of the disease, other forms of nourishment being added in later stages. This nourishment I give every four hours and no oftener. I do not consult the patient's appetite as to quantity, but give from four to six ounces whether desired or not. This amount given thus frequently is easily digested, and keeps the portal system moderately engorged constantly throughout its entire length, thus avoiding the condition of bloodlessness in which Peyer's patches and other glands become gangrenous and later on sloughing. If digestion becomes feeble, pepsin in some form may be given with benefit. Nausea and vomiting do not deter me from giving nourishment regularly; often nausea and vomiting occur from an accumulation of thick mucous in the pharynx, and care should be taken to have the patient thoroughly awake and throat cleared before taking nourishment. In such a course of diet the stools soon appear soft and of normal color, well stained with bile. Sometimes a diarrhœa appears, which may be checked a little by giving a few drops of laudanum. Three evacuations a day I do not check, nor should I give laxatives if a day passed without any evacuation.

The various germicides and disinfectants I seldom use. I believe physicians rely too much upon such inert, useless drugs. With a stream of nourishment constantly passing along the alimentary canal there is little opportunity for the development and absorption of deleterious germs and poisons into the system. Many of the cases of typhoid fever that I have treated under this method have solid stools pass them, of normal color and well digested; the glandular scabs being found only by washing the stools in warm water, which I do in all cases. Tonics and stimulants I give half-way between the times of giving nourishment.

When the temperature rises high, with a sluggish circulation in the ears and fingers, stimulants are called for in increased doses. If the Peyer scabs are watched for they will be good indicators of the condition of the affected parts. When the stools begin to improve I add to the diet eggs and more vegetable food. The first meat that I allow is pork tenderloin steak, broiled thoroughly all through. It should not be over six months old. I have found it to be a good article of diet in the convalescing stages. It digests easily and is very nourishing. It can be given long before beef-steak or any beef preparations can be borne by the stomach. I have fed it to patients now over twenty years and never have seen anything but good results from its use.

## PEPSIN.

JAMES E. FREE, M. D., Billings, Montana.

### MANUFACTURE ON SMALL SCALE.

Secure the mucosa from the cardiac end of a hog's stomach. Scrape to about half its depth after washing in clear water. Warm the scrapings to 40° Centigrade, with enough 2 per cent. hydrochloric acid solution to completely immerse. In ten days filter and saturate the solution with ammonium sulphate. Pepsin will be deposited in a slimy, sticky mass. Wash the filtered product in a saturated solution of ammonium sulphate. Again dissolve in a 2 per cent. solution of hydrochloric acid.

The next step is to dialyze it in running water to remove ammonium sulphate, and add thymol to prevent putrefaction.

Now add 4 per cent. solution of hydrochloric acid. Precipitate by saturation with ammonium sulphate; add 2 per cent. hydrochloric acid solution. Dialyze in running water. The result is a clear solution, which yields pepsin by concentration in shallow dishes at 40° Centigrade.

Pepsin is of a light brown color, opaque, and occurs in scales, crystals and irregularly shaped masses. Various minor peculiarities are met with, due to processes of elaboration. In home-made preparations the result is not identical in two cases.

Vast quantities of pepsin are turned out annually by the great pork packing establishments of the country, and as they advertise their product attractively and extensively, it has come to be a household

remedy. Physicians may think it a breach of the code to use the pepsin of some of these firms, but provided the drug is fresh, what harm to the patient can result? There are lots of poor, miserable code sinners in the ranks of the profession, and not a few who wear shoulder straps.

The pepsin used in medicine is usually obtained from the stomach of the hog. This is not an ideal source, especially for the Jew. A priori reasoning would lead us to suppose that the dog would furnish a better article. The hog is a vegetarian, whereas the dog and his master are omnivorous, but the hog is better adapted to grow pepsin, so he gets the appointment as politicians say. The ideal source would be the dissecting room, and until observers can point to results obtained by the use of pepsin second-hand our knowledge will not be scientifically exact. Pepsin in the stomach is a living entity. It is a fraction of human vitality. As used in medicine, it is dead Chemistry has supplied us with it as the substitute for the living ferment of digestion, just as it has given us infant's foods, or as dentistry gives us artificial teeth. Where the formation of the enzyme is interfered with it may possibly be good practice to attempt to pull the wool over Nature's eyes by administering the artificial product. If the stomach fails to secrete the proper amount of pepsin, it is proof that it is not in condition to handle the process of digestion.

Dyspepsia, which is caused by an enemy having its grip upon some of the vital organs, such as the vaso-motor system, the heart, or the central nervous system, needs a more radical agent than pepsin.

Before investigating the subject thoroughly, it is often the custom to cram pepsin into a stomach which is sympathizing with its hepatic or nephritic neighbors. Ordinarily ten grains in a capsule has no influence upon digestion. Spallanzani was the Columbus who discovered Nature's secret, hidden in the stomach.

### ANATOMY OF THE PEPTIC GLANDS.

The glands secreting pepsin are situated in a nidus of blood vessels. From the blood, by selection the gland is supplied with protoplasm which enables it to keep itself in repair and also to perform its function in life.

Endosmose and exosmose are illustrated by the processes which go on in these small organs. Continuous waste and continuous replenishing are the necessary results of activity. The gland, being faultlessly nourished, secretes from the protoplasm of the cells, granules which are elaborated into pepsin when a call is made upon the gland by stimulation. The amount of pepsin which the stomach can supply has a limit, and is measured by the granules of pepsinogen in the gland cells. As this is withdrawn to be put to work in the stomach, a fresh supply is stored up. This vital process is accomplished by the expenditure of energy. There is a point beyond which energy cannot be supplied. After that point is reached the symptoms of weariness will begin to show themselves. Continuous stimulation will lead to dyspepsia, but its origin is in the nervous system and demands not pepsin, but rest. Habit will accustom many of the vital processes to a routine not intended by nature.

Where such a routine does not demand an aggregate amount of work in twenty-four hours, equal to ordinary capacity, no harm results.

However, if three years digestive power is expended in two years, the individual grows old too rapidly. He is wearing out life's outfit more rapidly than is necessary. Much of the mortality before three score years and ten, is due to criminal waste of nature's forces. The digging up of such truths is regarded as the business of science. Longevity will hardly increase thus late in the history of the race. Its habits are fixed. It expects to commit these sins, and then demand of medicine that it shall be a shield against consequences. In nearly every case where pepsin is prescribed as an aid-de-camp of digestion, what is actually needed is no digestion at all.

Here is a coffee drinker who is nervous, unsteady and headachy when deprived of his customary stimulant. A dry eczematous rash is constantly present over the sternum. Drinking a pint of hot water three times a day for a week enabled him to break his habit. Appetite improved because digestion was better performed, owing to the fact that the gastric juice was not so largely diluted. Success so far led the patient to experiment further. He had been in the habit of eating three square meals daily. During a whole

summer only two meals per day were taken. Probably as much food was consumed each day as before, but a change for the better became apparent in the patients nutrition. Formerly he had been accustomed to use aids to digestion, such as pepsin and ingluvin. But since the gastric glands have a chance to get the necessary amount of rest, they no longer rebel and medicine is not needed.

THERAPEUTICS.

The ferment requires the presence of hydrochloric acid to do its work. Chemistry has not yet furnished nature a substitute for this particular acid. It required a long chase by science to settle the question of the secretion of hydrochloric acid by the stomach. In fact modern knowledge regarding the stomach is cumulative, extending over a period of one century. Each secret was wrested from nature by the use of instruments of precision.

An isolated stomach when wet is covered with a secretion on its mucous surface, which is glairy and viscid.

Rapid decomposition results in the exposed organ, and changes analogous to digestion are seemingly taking place on the surface from which the gastric juice exudes. The odor is that of pepsin, multiplied several times in offensiveness. Pepsin reminds the healthy nostril of what some call a bilious breath.

When food is ingested the secretory organs are stimulated. Without stimulation there is no secretion. Between meals the average stomach enjoys a period of hibernation. During functional activity, blood congests the tissues of the stomach, the granules of pepsinogen are elaborated into pepsin and freely poured out to unite with the other constituents of the gastric juice. The flow of gastric juice is not uniform any more than is the amount of pepsin. There are degrees of stimulation possible, and the conditions of the various organs of the body exert an influence, both upon amount and chemical composition. Medicines, emotions and mental effort may be supposed to modify the product.

Science now tells us that the changes accomplished in the digestion of food can be imitated by soaking food in superheated water. This shows us that the problem to be solved before creation, so far as a stomach is concerned, was to supply a resource which would do the work of heat, without heat. An evil heart of unbelief would have said before the fact, that such a thing was a wild idea. But there is nothing like demonstration to secure the complacent acceptance of a theory or condition. It is now in order for some bold and skillful operator, under antiseptic precautions, to perform stomato-pancreotomy on a dog, and show to the medical public that genuine happiness is possible by using boiled dinners without pepsin or pancreatic secretion. A seven league stride toward the radical cure for malignant diseases of the stomach will have been taken.

The quantity of pepsin in the stomach during digestion is small. It is necessary for the gastric juice to come into contact with every particle of food stuff, and where by this means the enzyme, in its acid medium, is thoroughly distributed, the splitting up of complex bodies goes on naturally. Ptyalin initiates the digestive process in the mouth when food is masticated. Acid pepsin continues the work by cleaving proteids into two groups: the anti-peptones and hemi-peptones. The former group respond to the action of pepsin and fit themselves for absorption. They are carried into the intestinal canal along with the hemi-group. The pancreatic ferment, trypsin, in an alkaline menstruum, acts on the latter group in a way analogous to pepsin on the former group. Food so treated is then ready for its journey to the tissues.

No actual change in pepsin itself can be proved. It encourages digestion by its presence; it is the mutual friend, the go-between of the stomach and the food. Being so thoroughly mixed with the food, some of it cannot help being assimilated. Once in the blood, in whatever chemical shape, it would naturally find its way to the stomach, where it would be selected as the basis of the elements elaborated by the gastric glands from the protoplasm of their cells to furnish granules of pepsinogen. Pepsin in solution is unstable. Before reaching the part of the alimentary tract where the waste of digestion is held in reservoir, it probably has been chemically annihilated. At least observers do not say that it is to be found there. The intravenous injection of a peptonized salt-solution, or the hypodermic injection of

the same ferment, might be a reasonable method of aiding digestion where secretion is deficient. The discovery of this wonderful agent seemed to open to the therapeutist a broad field which was quickly occupied. Some of the occupants have done nothing but rattle around and make a noise. Very few practitioners have not experimented with pepsin, and the name of the proprietary medicines with pepsin as one of the ingredients, is the Siamese twin of Legion.

In some conditions there is a lack of hydrochloric acid, for instance. There can hardly be a failure in the crop of one of the constituents of gastric juice, and a normal quantity, to say nothing of quality, of another. Digestion cannot be healthfully performed without the acid in the stomach. To pour out pepsin would be a waste of energy. Consequently, when a disproportion exists, nature calls a halt on appetite. Most likely an appeal is then made to therapeutics to force digested food into the intestinal canal. Stuffing is not feeding, and frequently nothing is so scientific as nothing in the shape of starvation. Where constipation exists for want of secretory activity in the gastric glands, hot water makes an excellent prescription. Whether or not acid and pepsin could be added to it with benefit is an open question. The hot water would probably be absorbed before it reaches the part of the alimentary tract where the sluggish contents lie. It is supposed to act by causing secretion from the mucosa of the stomach; by expediting transpiration; by its depurative effect upon the kidneys and liver; by a tonic effect to heart and circulatory system, through the action of caloric on their nervous connections, and by increasing peristaltic motion.

Strong peristaltic motion must be accompanied by freer flow of intestinal liquids. The contents of the channel becomes softer in consistence, and the passage is lubricated, so that the onward movement is favored when muscular action is present. If such activity was induced without secretion, the contraction of the bowel upon its contents would cause irritation, pain and inflammation. The chemical constitution of these contents would not be affected by pepsin.

Digestion, for example in enteric fever, must be carried on in the presence of a toxic ptomaine.

In tuberculosis, the bacillus or the product of its activity, complicates the problem of nutrition. The former condition demands rest; the latter does not call for digestive ferments any louder than for germicides to remove the obstacle to normal function.

All that is claimed for pepsin is that it aids stomach digestion. No virtue goes out of it to any systemic process. Its field is circumscribed to the pouch, called the stomach, which is, first, a receptacle; second, a depot of supply for the material of digestion; third, the place for the performance of so much of the function as can be accomplished in an acid medium. The applicability of an agent which would digest food anywhere in the channel is at least questionable. Only a part of the alimentary tract seems to be adapted to the process.

Nature winds her own clock. If portions of food prove too obstinate for cleavage and hydration, they are forwarded as rejected material. Frequently it is not power to digest articles of food which is demanded, but rather a change of food.

The division of the channel into such well marked sections, must bear some relation to function.

# EUTHANASIA.

CHARLES B. WILLIAMS, A. B., M. D.,* PHILADELPHIA.

"Inveni portum; spes et fortuna valete."

"I have found my Euthanasia, farewell to the battle of life."

Euthanasia means an easy, happy death. The word occurs in Pope's Dunciad, and Lord Byron has a poem so entitled. Seneca, Marcus Aurelius, Sir Thomas More and Lord Bacon were all advocates of euthanasia, and have each written more or less upon the subject. Since then writers have at long and irregular intervals taken up the subject of euthanasia, but very little study has been given to it really; it should, therefore, be a sacred duty of every physician to make this subject a part of his studies, and in the words of Lord Bacon, "it should be as much his duty to smooth the bed of death, and render the departure from this life easy and gentle, as it is to cure diseases and restore health." And where there is no hope, after the physician has exhausted all the resources known to science and has found that it is a case not within his power, "to retain the ties of life," then it should be a grateful and sacred duty, nay, it should be the highest triumph of the physician to minister unto the wants of a dying fellow creature by effecting the Euthanasia.

Death is the separation of the spiritual part of man, the soul, from his body. Yet, in reality, we know not what death is, for "we cannot argue from *the reason of the thing* that death is the destruction of living agents, because we know not at all what death is in itself, but only some of its effects, such as the dissolution of flesh, skin and bones. And these effects do in no wise appear to imply the destruction of a living agent,"† no more, in fact, than the planting of a seed into the earth, for with its apparent dissolution or destruction the plant is born which, in a short space of time, buds and shoots forth its leaves and flowers and becomes a thing of joy to the heart of man.

The same fate awaits all, whether he be emperor or plebian, rich or poor, a prince or a vassal. "When thou takest away their breath they die, and are turned again to their dust." (Ps. civ. 29.) In the charnel house the skeleton or dust of the king will not be distinguished from that of his subject; and Seneca has truly observed that "in this world, men are born of unequal rank, but after death all will be equal."

When the act of dying has already begun, the following signs, first observed and tabulated by the Father of Medicine, Hippocrates, will be noticed: "The nose becomes sharp and pinched; the eyes are hollow and sunk in their orbits; the ears become pale, cold and shrunken, with their lobes inverted; the face is pallid, livid, or black." These signs conjointly have been termed the *facies Hippocratica.*

Contrary to popular belief, the process of dying, or the act of death itself, is *rarely* and exceptionally attended with pain or severe bodily suffering. Physicians who have had ample opportunities of observation from their connection with hospitals or in their private practice, clergymen and intelligent nurses will all bear witness to the truth of the statement.

Sir Benjamin Brodie, whose experience in death from surgical disease was vast, states that from his observation, the mere act of dying is seldom, if ever, a very painful process. Anyone who has had practical experience as an hospital interne will have observed that most all severe forms of injury resulting from railroad accidents, crushes, fatal burns, scalds, etc., while the patient may suffer acute pain early, and for a short time after sustaining the injury, yet as death approaches the end is not one of intense suffering but, on the contrary, is calm and peaceful. On the other hand, take some painful affections of the heart. Here, as in surgical cases, the same rule holds good. This may be exemplified by quoting the words of the celebrated English anatomist, Dr. William Hunter. A few moments before his death, turning to his friend, Dr. Combe, he said: "If I had strength enough to hold a pen, I would write how easy and pleasant a thing it is to die."

Persons who have recovered from apparent death by drowning have all, with one

*Ex-resident physician Pennsylvania Hospital; Dispensary Surgeon Methodist-Episcopal Hospital, Philadelphia.

†Vide Bishop Butler's Analogy of Religion, p. 94.

accord, stated that there was an entire absence of pain or suffering of any kind, while throughout the period of consiousness the mind was keenly active—thought succeeding thought with marvellous rapidity, the whole life of the person being reviewed during the short period of suspended animation. The same facts have also been observed by those who have been partially strangled or hanged. Lord Bacon, in his History of Life and Death, states: "I remember to have heard of a certain gentleman that would needs make trial, in curiosity, what men did feel that were hanged; so he fastened the cord about his neck, raising himself upon a stool, and then letting himself fall, thinking it should be in his power to recover the stool at his pleasure, which he failed in, but was helped by a friend then present. He was asked afterward what he felt; he said he felt no pain, but first he thought he saw before his eyes a great fire, and burning; then he thought he saw all black, and dark; lastly, it turned to a pale blue, or sea-water green; which color is also often seen by them which fall into swoonings."

*Treatment of those dying*: In many cases the consciousness and intelligence remain unimpaired to the last. It is in such cases that kind words and beneficent acts will go far towards assuring a peaceful end to the patient. "To the dying there is no greater solace and cordial than hope—it is the most soothing and cheering of our feelings, and if, when all hope of life and in the present has fled, the dying man can dwell with hope and confidence upon his future, it will be well for him. The retrospect of a well spent life, "Memoria bene actæ vitæ, multorumque benefactorum recordatio," is a cordial of infinitely more efficacy than all the resources of the medical art; but a firm belief in the mercy of God, and in the promises of salvation will do more than anything in aid of an easy, calm and collected death."*

As long as the dying person is able to swallow, wine, cordials, and food, in such a form as will prove most acceptable to the patient, may be given from time to time. Some may ask: Of what use is it to give nourishment and stimulants to a dying person? The mere fact of showing one's concern for him about to depart this life, will be more than appreciated by the patient and will effect his euthanasia. Even our Lord did not disdain or refuse a cooling draught when suffering death. For when his expiatory sufferings on the cross were at the point of being finished, He said: "I thirst;" and the exquisite pain, heat and torture doubtless caused his thirst to be intense. Straightway then ran some of the soldiers, and filling a sponge with vinegar (a mixture of vinegar and water was commonly drunk by the Roman soldiers), they offered it to him upon hyssop. St. John (Chap. xix. 30) tells us that our Lord received and tasted the vinegar and immediately gave up the ghost.

The bed-chamber of the dying should be made as light and cheerful as possible, for the question at issue is the passage of a fellow-being into a life, it is to be hoped, that is spiritual and bright. And frequently the patient himself will exclaim: "Mine eyes fail me, my sight grows dim; give me more light." This dying request should be immediately granted, for it will not only lessen the cares and gladden the heart of the departing one, but it will possess an additional interest from the fact that it may be the last favor that we may be permitted to confer upon one who has been dear to us. It should not be forgotten that the sense of hearing in the dying is often very acute, and that it is one of the last of the faculties to be destroyed. Hence all loud conversation should be avoided, lest it interfere with the patient's peace of mind.

When the mouth and tongue are dry and parched, a few drops of iced-water or a small bit of ice will afford great relief to the patient. The drugs that will be of service in effecting the euthanasia are few indeed. They may be counted upon the fingers of one hand. Of these *opium* stands first, and next in order are *cannabis indica*, *cocaine*, *spirits of chloroform*, and *ether*.

Opium should rarely, if ever, be administered to the dying as an hypnotic, on account of the risk of throwing the patient into a sleep from which he may never awaken. The sole object for its administration should be for relief of pain. By the relief of pain, often an apparently refreshing sleep is induced from which the patient awakens more com-

* Vide Euthanasia, by William Munk, M. D. F. S. A. London, 1887.

posed, and he is thus able to depart more easily when his time comes. In cases of phthisis, or where opium is contraindicated, some preparation of cannabis indica may be administered, preferably the fluid extract or the tincture.

Cocaine in small doses may also be used where there is much tendency toward depression of spirits. Or in place of the alkaloid a mixture of the fluid extracts of cannabis indica and coca may be given.

And lastly, where there is great difficulty in breathing, whether from some disturbance of the heart or lungs, or where there is flatulent distension of the stomach or abdomen, a few drops of spirits of chloroform may be given, or of ether, best administered either under the form of Hoffman's anodyne or of "ether punch," the formula for which is the following:

℞ Aquæ mentæ viridis.....f℥ vss.
Sacchari.....ʒss.
Acid. sulphurici diluti.....mxl.
Spts. ætheris comp.....f℥ij.

Misce et ft. mistura.
Sig.: Pars quarta pro dose.

Many cases will require no medication whatsoever, and in any case, probably, the less medicine that is administered the better.

S. D. Williams, Jr., in an able article on Euthanasia, published in London, 1872, endeavors to establish the reasonableness of the following proposal: "That in all cases of hopeless and painful illness, it should be the recognized duty of the medical attendant, whenever so desired by the patient, to administer chloroform, or such other anæsthetic as may bye-and-bye supercede chloroform—so as to destroy consciousness at once, and put the sufferer to a quick and painless death; all needful precautions being taken to establish, beyond the possibility of doubt or question, that the remedy was applied at the express wish of the patient."

The above statement would make an excellent text for a long essay or a spirited debate in a medical society. At the time of its publication it created no end of discussion. In answer to it:—It were better, by far, that chloroform had never been discovered, rather than it should ever be put to so base and awful a use as to wilfully take away the life of a fellow creature in order to effect his Euthanasia.

# COMMUNICATIONS.

## A CASE OF EXTREME LOW TEMPERATURE.

GEORGE R. DEAN, M. D., Spartansburg, S. C.

Mrs. S., sent for me on October 11, 1893. I found her dressed but reclining on the sofa. She had been complaining of pain in the calf of the left leg for several days, and upon examining it I found a plexus of enlarged veins, with knots outlying in several directions. The leg was not swollen except at the point where the trouble had occurred, a place as large as say the half of one's hand. There was pain and tenderness on pressure and some constitutional disturbance—not much, however; tongue coated; pulse a little fast and accentuated somewhat in its beat; bowels constipated. Gave small dose of calomel and soda every two hours for four doses, followed by salts. I bandaged the leg instructing her to remain perfectly quiet, to occupy a horizontal position as much as possible, and to be up only when compelled to answer the calls of nature. This occurred on Tuesday 11. I did not hear from her again until that day one week, October 18, when I was called again. I found her in bed this time, with the leg swollen to the foot, and œdematous even above the knee. Temperature 101° F.; pulse about 90; skin looked sallow and thick. She seemed rather dull, just as would be expected from the trouble in the leg. This had extended on every side, and was very tender to the touch. Prescribed witch hazel, quinine with laxatives, and pressure by bandages.

I saw her every day for the next eight weeks, and during that time a succession of symptoms developed that were peculiar and some of them surprising to me. She early showed symptoms of disturbance of the brain and became to a certain extent

unmanageable. For instance, if medicine did no taste or smell agreeable to her she would not take it at all, and thus she would often go without medicine for a whole day, or until I could see her and change her prescription to a more agreeable dose. During the week following after my second visit her temperature rose gradually from 101° to 103.5° F., and the swelling in the left leg gradually increased until it had reached the hip. A condition of typhoid now developed and for three weeks the trouble in the leg was at a stand-still—headache, diarrhœa, tympany and the dull, sodden countenance, with the temperature ranging from 101.5° in in the morning to about 103.5° in the afternoon; pulse full and strong; tongue dry, furred and red. Her mind at the end of four weeks from the beginning of last trouble, or about November 15, had become almost *nil.* She was unconscious of all around her save when aroused, and then no reliance could be placed upon her report of herself. Often she would tell long stories about herself that were totally at variance with facts.

At this time, as her fever began to decline, I suddenly discovered one day that her temperature had fallen to 97.5°. This I could not account for. The next day I found trouble in the bladder. It was tender, painful, and soon became paralyzed, and, my attention being called to the fact that she had passed no water for some time, save a little dribbling, I found it full, and emptied it. She had no sensation of distention, and when asked about it, said she had no desire to pass water. This kept up for five or six days, when she could again void the urine herself. Peritonitis followed and then I began to think the end was near, as did also Dr. Heinitsh, who visited her with me. We could see no cause for the peritonitis save the sepsis from the original phlebitis. As this, under careful and supporting treatment, gradually subsided, her temperature began falling during several hours a day to 96° After this trouble had about subsided, her heart became involved. She complained of great pain in this region, and a distinct systolic murmur could be heard at the apex. Temperature fell during this time to 95° for a few hours each day. As the heart trouble improved, pneumonia of right lobe set in, and with great difficulty she kept up the respirations. Often they would amount to 60 to the minute, and one day, by actual count, they reached 72 per minute. I kept close to my patient now, as each day seemed to usher in some new trouble.

The pneumonia lasted six days, and she weakened perceptibly, but I had her take all the nourishment possible. Strychnine, digitalis and ammonia constituted my principal treatment, with counter-irritation and fomentations over the lung. The urine now showed much albumen, as would be expected, and in a few days œdema of the face, eyes and hands set in. Before this, however, both legs again became involved with phlebitic knots and corrugated varicose veins. I kept both bandaged from now on until convalescence was established. As the cheeks became œdematous, the temperature reached 93° for several hours each day. I thought surely the end could not be far away. I tested the temperature with three different thermometers, and they did not vary one-fourth of a degree. I could not take the temperature in mouth or vagina, for, notwithstanding my patient was in a partial coma, she would know when touched, a d fight any and every one who did anything to her, save such as she herself wanted. Often for a whole day I could not prevail on her to take food and medicine or show me her tongue, and it was with the greatest difficulty that her wants could be made known to us, her speech was so indistinct.

Her right side now showed signs of paralysis. She ceased to move the right leg or arm, and would not change her position for days at a time. After some days the anasarca began leaving slowly, and my hopes were again elevated, as much as at the various stages they had been cast down. She began to eat and sleep better, and noticed those in the room and seemed to be better generally. On one of my morning visits a few days after these signs of improvement, I was told by the nurse that the temperature was down again—I examined and found it at 92½° I knew there was some mischief somewhere brewing, so I examined every organ in the body to see where the stroke would be, but I could find nothing save slight tenderness of the bladder. The next day temperature 92°, coma almost complete, discharges involuntary, and nothing seemed to recall my patient to things around her. I detected a fearful odor in the room,

different from anything I had experienced before, and was told it was from the bowel. I could scarcely believe it and examined the bladder per vaginam and bi-manually. Upon pressure over that organ, and counter-pressure in vagina, with frequent and loud expulsive sounds of gas escaped from the bladder, and such an odor! That at once accounted for the disagreeable scent in the room. I at once began washing out the bladder with boracic acid, twice a day. For several days no improvement was detected. Enormous quantities of flatus and mucous membrane came off each day, but soon began to lessen, and in ten days all the trouble seemed to pass away.

The stomach, which always sympathized in her troubles, now returned to its wonted standard, and the appetite and digestion were all that could be asked. From this time on she steadily improved. Only one serious relapse—after eating a quantity of hash, of which she seemed especially fond, she had an attack of cholera morbus which soon passed off.

Her temperature for several hours at a time would fall to its lowest ebb and in the last attack, fell to 92° five days successively, but at no certain period. It would be down to-day at 10—to-morrow at 5 A. M., next day at 5 P. M., etc.

On Feb. 11th, she took her first airing out-of-doors—and seems now to be regaining her mental and physical strength. The range of temperature here was extraordinary. The difference in the highest and lowest points being 11½°.

N. B.—One year after the above notes were taken down, this patient is well and attending to her domestic duties, apparently in better health than for several years previous to her illness.

## TRAUMATIC MENINGITIS.

FRANK E. COUDERT, M. D.,* WALLINGFORD, CONN.

On March 8th, 1894, I was hurriedly summoned to see D. C., an infant girl, aged fifteen months.

The following is the history I obtained from one of the bystanders:

Mr. and Mrs, C—were out at the time of the accident, the child being left in charge of a competent (?) nurse. The nurse having work to do in the attic, brought the child along with her for safe-keeping. Suddenly D. C., who was just learning to walk, broke away from the girl and threw herself against the window, which was opened, and only four inches from the floor. She went head-first out, and landed upon her head on the ground beneath, a distance of thirty feet.

When I saw her, thirty-five minutes after the accident, her face was greatly cyanosed, respiration rapid and irregular, pulse small and feeble. I gave her twenty drops of brandy by the mouth. In a few minutes an improvement was seen. The face became normal in appearance and the pulse regular.

On examination the only injury I could find was a slight brush-burn on the right side of the head, extending from the upper border of the parietal to the middle of the temporal bone. I gave strict orders to keep cold applications upon the head during the night. Five grains of bromide of potash were given every four hours throughout the night. She passed a comfortable night and a good forenoon. On the afternoon of the 9th, a marked change for the worse occurred, being in a comatose condition with a marked strabismus; temperature 103°, pulse 140.

On the 10th, at 9 A. M., Dr. W. S. Russell was called in consultation. We agreed that we had a case of traumatic meningitis to deal with, and the following plan of treatment was settled upon.

Constant application of cold to the head (the cold coil being used). Five grains of bromide potash every four hours; one-quarter of a drop of tincture of cantharides with two grains of iodid of potash every six hours. A cantharideal blister behind both ears. Brandy P. R. N.

Early in the morning of the 11th, our patient was in a state of collapse. Hot water and milk were used per rectum, while small doses of compound spirits of

* Member of the New York County Medical Association and the Connecticut State Medical Society; Town Health Officer.

matics who often suffer from urticaria, tried it in cases of uncomplicated chronic urticaria where the usual means had failed. He has treated with success four rebellious cases; a fifth was acute and of five days duration. None of these cases were syphilitic. All he cured rapidly by the admistration of a solution of potassic iodide in the proportion of 2.5:100.0; of this three soupspoonsful, three times a day. In a case which had persisted for four months, the atrocious itching disappeared on the second day of treatment; a complete cure was obtained after taking ten grams, (ʒijss), of the drug. In two other cases of longer duration, two and a half and six years respectively, the effect was similar and a definite cure followed after ingestion of respectively twenty-five and seventy-five grams of the iodide. Finally, in two others, one an acute and the other a recurrent case of three years duration, the drug increased the pruritus at first, though this was but transitory and a cure was obtained with five grams. These observations though not numerous, indicate that the iodide of potash is worthy of being classed amongst the remedies for urticaria. He also referred to a case of chronic urticaria successfully treated by Wilson with this same drug.

---

RESORCINE IN ULCER OF THE STOMACH.

Dr. Pope (*Memorabilien*, No. 2, 1894), recommends a two per cent. solution of resorcine as the most efficacious remedy in the treatment of round ulcer of the stomach. A tablespoonful before each meal. Also rest and appropriate diet.

---

FEVER OF TUBERCULOSIS IN CHILDREN.

Dr. B. Rachford (*La Semaine Madicale*, No. 31, 1894), in the fever of tuberculosis in children, advises the following salve:

℞ Guaiacol,
Lauoline.....āā 4 | o (ʒi).
Lard..... 30 | o (ʒj).

Rub a piece of the size of a small nut, every evening into the thorax.

---

TREATMENT OF THE CARDIAC WEAKNESS OF ARTERIO-SCLEROSIS.

Dr. A. Smakowski (*Memorabilien*, No. 2, 1894), has employed the usual treatment of the final period of arterio-sclerosis which is accompanied by cardiac weakness, as valerian, ether, digitalis, strophanthus, caffeine, etc., and in two cases has observed embolism of the cerebrum—arteria fossæ Sylvii—to follow. He thinks it more rational to administer in such cases only narcotics. These relieve the heart in that they act as sedatives to the nervous centres. Choral hydrate and small doses of morphine were used by him. During the attack he administers:

℞ Chloral Hydrate
Bromide Sodium.....aa 4 | o (ʒj).
Codeine..... o | 1 (grs. jss.)
Distilled water.
Syrup Orange Peel....aa 45 | o (ʒj ʒiij gtts. xv.)

A tablespoonful every two hours until the patient becomes quiet. Not more than three tablespoonsful in succession.

Besides ice is applied to the region of the heart, subcutaneous injections of morphine are given ($\frac{1}{10}$ gm.), absolute rest and a light diet. After the patient has been quieted he then administers heart stimulants.

---

EAU DE COLOGNE IN COLDS IN THE HEAD.

Dr. Roux (*Norsk Magazin for Lægevidenskaben*, No. 5, 1894) recommends Eau de Cologne in the treatment of acute rhinitis. A little is poured onto a handkerchief and inhaled forcibly for several minutes through the nostrils. This is repeated five to six times a day. In eleven cases he has observed good results, even in cases where there was a slight rise of temperature. He thinks that thus he has been able to abort a cold for several of his patients, who when they would take cold in the nose it would be followed by a tracheo-bronchitis. The remedy was of the following composition:

℞ Ethereal Oil Bergamot,..... 10. | o (ʒijss.)
" " Sweet Orange,.. 10. | o (ʒijss.)
" " Lemon,..... 2. | o (gtts. xxx.)
" " Rosemary,..... 2. | o (" xxx.)
" " Bitter Orange,.. 2. | o (" xxx.)
Alchol, 900..... 100. | o (ʒiij ʒj.)

---

PILOCARPINE IN PANCREATIC COLIC.

Prof. Eichorst (*La Semaine Médicale*, No. 31, 1894,) in a case of pancreatic colic; pain in the right hypochondrium, fever, ptyalism and intermittent glycosuria, caused the pain and other symptoms to disappear by hypodermic injection of, at first, one c. cm. of a 0.5 per cent. solution and later, that quantity every two days. The drug favors expulsion of the pancreatic calculi by increasing the secretion of pancreatic juice.

## EDITORIAL.

### STYLE IN MEDICAL WRITING.

The late Dr. John Brown, whose *Horæ Subsecivæ* a doctor will not fail to read, and having read once will read again, said that our medical writers now-a-days, with a few signal exceptions, write ill; that they are slovenly, diffuse, often obscure and curiously involved. Among the reasons given by Dr. Brown for this condition are, the enormous amount of merely professional knowledge a man is expected to master before he writes on any subject, and the absorbing nature of the new methods.

One of the causes of bad writing in modern compared with ancient times, which applies of course not exclusively to medical literature, is punctuation. It can be readily understood that those writing before the art of punctuating obtained, were compelled to be very accurate in syntax, else the force, if not the meaning of the utterance would be lost. It was also impossible for them to make the long sentences we find to-day, especially in many German writers. Punctuation came with typography, and as a consequence we may meet now and again a sentence crowded with clauses and qualifications, sometimes indeed not free from episodes, so that the chief thought, or thoughts would be lost were not a clue given by punctuating marks. The witty New York lawyer and statesman, who is famous for his prolix passages, once answered a critic by saying, "Criminals always object to long sentences." But in composition such sentences weary the reader and often obscure the thought. The error referred to may result from the employment of unnecessary words. How often, for example, a noun strong enough in itself is loaded with two or three adjectives; the writer is straining after effect, as it is called, and in the effort loses it. Further, unrelated things are dragged into a sentence, making an incongruous mass of words, and length, not beauty or strength, results. Clear thinking will lead to clear and condensed expression. Life is short and

time is fleeting, especially with the doctor, and he greatly prefers extract of beef, or a good steak or roast, to being compelled to devour horns and hoofs, tail and tallow, skin and bones in getting his needed nutriment.

The medical writer should take for granted that his readers know something —it is not necessary for him to tell them how to spell baker—and hence let him omit all unnecessary facts and details in his communication: thus doing he will have more readers, and they will know more.

We have alluded to straining for effect, in one of its forms, as an error in writing. There are other ways in which this is intentionally done. For example, there are writers whose style is purely artificial, who affect tricks of words, peculiarities of expression and extravagancies of statement, as if they were shouting, "Listen to me!" Whatever is well-said carries in itself the call for attention; hysterical rhetoric, which has no more force than foam upon the waves, is not needed; nor is mental tympany, which goes off with a great noise and nothing else. Such writers are in no respect good models of style.

As little worthy of imitation is the egotism manifested by some writers. Money-making is the chief purpose of their lives, and their goods have a trade mark. I is so often repeated in their writings, the egotistic nature is so plainly and painfully apparent, that the first person singular cases to be singular, is indeed multi-plural, and one finds I as frequent on a page as eyes of another sort are numerous in the tail of Juno's bird. To the unwary it seems as if these egotists possessed all wisdom, knowledge and skill, they only understanding what to do, and how to do, and to them let all patients be consigned. That this sort of work pays, as the saying is, seems evident from the large number engaged in it.

Nevertheless, the best professional work, the most useful and abiding, must be that stimulated by unselfish motives and a high ideal. The honest and conscientious physician will especially ponder the wise words of Lord Bacon, so applicable to medicine, that "knowledge is not a shop for profit and sale, but a rich storehouse for the glory of the Creator, and the good of man's estate."

So many topics crowd upon us, and space is so limited, that we are compelled to restrict the conclusion of this article to some remarks upon the means by which a doctor may acquire a good style.

As our manners are largely formed by the society in which we move, so our writing depends chiefly upon the authors we read. Among medical writers none is superior to Watson. It is a pity that his work on medicine is no longer a text-book, for its study would be most helpful to young doctors in acquiring a style at once clear, strong and graceful. It would be well for the physician, though having more recent volumes upon practice in his library, still to keep that of Sir Thomas Watson, and to read in it from time to time. Works upon diseases of women and upon diseases of children are numerous, but we know none equal so far as literary merits are concerned, to those of Dr. Charles West. We have sometimes wondered whether the multiplicity of illustrations, plates and wood cuts, furnished for professional books now-a-days has not caused carelessness in writing; for why describe accurately and clearly, why make a word-picture, when an illustration can be used?

While selecting Watson and West as models of medical writers, other names could be mentioned of men whose pages delight while they instruct, but we must pass to general literature, making brief reference to the part which the study of certain authors or books contributes to the obtaining of a good style.

The Bible should be placed first among books of study for this purpose. Cole-

ridge said, intense study of the Bible will keep any writer from being vulgar, in point of style. We add that such study will help give clearness, simplicity, beauty and strength of style. And here permit an apparent digression. An authority in architecture once said, if you are in doubt as to the color your house in the country should be painted, pull up a native shrub or small tree, and notice the color of the soil that adheres to the roots. That should be the color of the house. So, too, if one observes the language used by plain people, men and women of average education, when a great trial or sorrow comes to them—some deeply rooted object of love torn from their hearts—he will often be struck with the simple strength of their words; he will have a higher appreciation of the English tongue, and learn an important lesson in its use. Now these plain people to whom we refer, most probably are more familiar with the Bible than with any other book, and chiefly got from it their mode of speech.

All are familiar with Johnson's remark: "Whoever wishes to acquire an English style, familiar but not coarse, and elegant but not ostentatious, must give his days and nights to Addison." We would like to add several other names to that of Addison, as authors to be read in the study of style. We urge a place for Swift, who wrote with such perfect command of language, and so accurate a discrimination in the choice of words; we wish that doctors would read Fielding, and it would be unfair to one of their own guild to omit Smollett. Southey will be read, at least that quaint volume so rich in various learning, "The Doctor." Of course they read Shakespeare, and an occasional page from Jeremy Taylor will enrich their minds with noble sentiment, classic learning and poetic imagery. It would be professional disloyalty not to read Sir Thomas Browne, more especially "Urn-Burial," "Christian Morals, and last, though not least, *Religio Medici*.

Let us say a word for Coleridge. More than thirty years ago an American physician was the guest of an eminent member of the Dublin profession, and one evening the conversation happened to be upon this great philosopher and poet, when the Dublin doctor gratefully spoke, "Coleridge taught me how to think." The "Aids to Reflection" had been the special means of instruction to this distinguished doctor and author, long since dead. And therefore we urge at least this volume upon doctors who desire to know not only how to think, but also how to write.

The list of authors is by no means complete; we could justly add the names of Pascal, Macaulay, Emerson, Holmes and Ruskin, and advise occasional reading of DeQuincey to note the careful selection of words and their admirable arrangement so that a sentence is built up like a Grecian temple, perfect in beauty and strength. Among poets in the doctor's library, we ask a place for Tennyson, Mrs. Browning and Longfellow.

But for the present we dismiss the subject, trusting that some little has been said which may be helpful to the writers of the profession, who may be sincerely desirous of acquiring a style which shall be attractive and effective in communicating their thoughts.

# SOCIETY REPORTS.

## ORTHOPÆDIC SECTION, COLLEGE OF PHYSICIANS.

*April 20th, 1894.*

### DR. T. G. MORTEN PRESENTED, THROUGH DR. WOODRIDGE, CASES OF DOUBLE EQUINO VARUS WITH REMOVAL OF ASTRAGALI.

Case I. Mary J. McK., one year, ten months old; living at Bryan Mawr, Pa., congenital, uncomplicated, talipes equino-varus. Operation of division of tendo Achilles performed February 21st, 1894, Posterior right-angle tin splint for a week, followed by ordinary brace, side steel support. April 20th, apparatus discarded every other day and plain shoe allowed. Foot in good position. Result perfect.

Case II. Benj. Jordan, two and a half years old. Living in Philadelphia. Double uncomplicated, congenital talipes equino-varus. April 5th, 1894, operation of division of tendo Achilles and tendon of anterior tibial by open incision. Rectangular, posterior splints, dressed a week after operation. Also division of flexors of all toes,

Case III. Orm Gantt, 5 years old, living at Island Heights, N. J. Admitted into the Orthopædic Hospital January 17th, 1894, with the statement that he had been deformed ever since birth; having double Talipes equino-varus so that in walking his feet were turned in, so that he walked upon the dorsum of each foot. When 8 months old he had been operated upon at the University Hospital. He then wore braces until 3 years of age. He did not remain in the Hospital after operation and the after treatment was probably neglected.

After admission, his feet were poulticed for three nights, in order to soften the callus on the dorsum of each foot. The operation was performed on the 25th of January. Dr. Morton severed the flexor tendons of all the toes, the anterior tibials and the tendo Achilles of each foot. He also made an incision three inches in length on the outer aspect and dorsum of the feet through the callus, and simultaneously removed the astragalus and part of the cuboid bone of each foot. The rectangular, posterior, tin-splints were used as in the other cases. There was no rise in temperature after operation, Dressed for the first time on the 8th of February. Wound well healed. He continued to wear the rectangular tin splint until March 3d, when braces were applied which he is still wearing. Feet are now straight and in good position. Wounds entirely healed.

#### DISCUSSION

DR. G. G. DAVIS: There are two things in regard to this case which occurs to me. First, as a rule I do not believe in open incision. The only advantage is when one cuts down upon bundles of contracted tissue; but in division of a healthy tendon, in an equally healthy patient, I do not think it necessary. In a case of torticollis where we have dangerous structures in the neighborhood, and where there are contracted tissues and a tendon that does not slide in a synovial sheath, then I would use an open incision,

Some time ago I showed at the County Medical Society several cases of wedge-shaped resection. As for myself, I have never seen a case at the age of five years in which I could operate upon the bones. In one case which I showed at the College of Physicians, aged six or seven years, the child walked upon the dorsum of the feet, toes pointed toward each other and the sole vertical, yet it was cured without operating on the bones. The bones in cases of this age are soft. I showed an astragalus, removed by another surgeon, which was so soft that I could push a pin through it, with my finger, in all directions.

I do not believe that excision of the astragalus alone, in cases which demand operation on the bones, will straighten the foot; therefore when bone is required to be removed I believe the deformity can only be rectified by severe measures. In removing the astragalus, a portion only of the obstruction is removed and the external arch is left intact, and the deformity which remains is so great that it demands further procedures on the outer side of the foot, such as a removal of a portion of the cuboid or anterior portion of the calcaneum. A foot that can be straightened by removal of the astragalus alone is usually one which can be cured without operation on the bones.

DR. WOODBRIDGE: I thank the Section for the courtesy of allowing me to present these cases, and as I have another engagement I will not enter the discussion. I have only one word to say, I understand that Dr. Morton never removes an astragalus when it is in place; it is only when it is deformed.

DR. DEFOREST WILLARD: In tenotomy of the posterior tibial tendon, especially in fat infants, open incision is desirable. No surgeon, however, works in the dark in sub-

cutaneous section of the tendo Achillis and this method is just as exact as the open one since an amount of material will be thrown out, proportionate to the separation of the cut end.

---

ABSTRACT OF "REMARKS ON THE USE OF A BRACE IN LATERAL CURVATURE FROM EMPYEMA."

DR. G. G. DAVIS: At a recent meeting of the Section, when I exhibited a patient about 7 years of age wearing a brace for the correction of lateral curvature resulting from empyema, the views expressed by some present were so at variance with my own, as to induce me to more carefully examine into the subject and ascertain whether the brace, as ordered, was likely to be of service and desirable.

A discharging sinus, existing in the left chest wall of the child for more than a year, was only recently cured. Examination posteriorly showed the whole trunk, from the pelvis upward, inclined toward the right side with a slight lateral curvature in the upper dorsal region, the convexity being to the right. The right shoulder was higher than the left, and the right scapula formed quite a prominent projection. Laterally, there was a slight forward inclination of the right shoulder which increased the prominence of the right scapula. On the left side there existed the scar and depressed cicatrix where the ribs were excised; and contraction of the altered intra-thoracic tissue had taken place, accompanied by sinking in of the chest wall and lowering of the left shoulder.

As the general object in using braces and apparatus is to correct certain alterations in the form of the body, let me examine the mechanical problems suggested and the means taken to solve them. First, then, as the deformity was confined to the upper portion of the body, therefore the means of correction were applied to that part. Again as the lower portion of the body was normal, it furnished a fixed point of support for the application of the correcting force, consequently a steel band was made to encircle the pelvis between the great trochanters and the crests of the ilia, and fastened in front by a strap and buckle. To increase the hold of the band, a wide linen belt was attached to it, and reached from the trochanters to the ribs. It was secured by two buckles in front. Four steel uprights were attached to the steel band, one under each axilla, and one on each side of the median line posteriorly. A transverse steel bar was fastened to the upper ends of the uprights, and curved so as to be high in the middle of the back and low under each axilla, forming a crutch.

Placing the child on his back and firmly strapping on the brace, corrected the lateral deviation of the trunk. Next, to correct the elevation and forward inclination of the right shoulder and accompanying projection of the scapula, a strap was passed from the anterior end of the right crutch over the shoulder and attached behind. This drew back the shoulder and corrected the tendency to stooping. Finally, to make lateral pressure over the projecting lump in the right upper thoracic region, a wide elastic band was fastened by straps to the right axillary upright on the left side of the spine. This made excellent pressure and completed the requirements of the brace. An apron had been attached by the mechanician, but as there was no necessity for it, I removed it.

In another case, instead of fastening the elastic band to the axillary upright, I shall attach it to one running between the anterior extremity of the crutch to the pelvic band, and so obtain a more directly laternal force. This brace offers no hindrance to the free expansion of the contracted chest, and in no way prevents the patient from running, playing, or indulging in exercises and gymnastics, such as swinging from rings, horizontal bars, etc. Morning and evening, after removing the brace, he exercised by bending forward and backward and from side to side. The most important principle involved in the use of the brace in this class of cases is the means to be adopted to secure the expansion of the affected lung and chest wall. Is it better to allow a patient, with a recently healed wound and a marked deformity, to go without any attempt at correction on our part, or should we, by a portable brace, endeavor to maintain a gentle and persistent pressure on the distorted parts which will cause the contractions to gradually yield, yet not interfere with the expansion of the affected lung; while at the same time, the child is prevented from assuming any posture favoring persistence of the deformity? I have preferred the latter with such exercises as he can take, believing it much more efficient than the spasmodic stretchings of intermittent excercises, interspersed with periods in which the body will be inclined to the affected side and every oportunity given for contraction to take place. After the deformity has been partially reduced and the tendency to assume objectionable positions somewhat overcome, the brace may be discarded and therapeutical gymnastics alone employed.

SCOLIOSIS.

DR. J. HENDRIE LLOYD: I have no set paper. I simply wish to make a few remarks and to show a few photographs. I think the nervous origin of the disease is not sufficiently recognized by surgeons. It is important that it should be. It is seen especially as a complication of nervous diseases, as syringomelia. In a recent monograph, Bruhe says

that in fifty per cent of cases of syringomelia, scoliosis occurs. Some of these cases are also associated with marked kyphosis.

One case of syringomelia has come under my notice in which the deformity was similar to that shown by the skeleton here exhibited. One point in connection with scoliosis in syringomelia, is shown by this photograph. In some cases when the patient is in the recumbent position, the deformity is obliterated. This case, seen in the photograph, simulates torticollis, because the scoliosis is high in the cervical region.

The second case with which scoliosis is associated is Freidrich's ataxia. It is a disease of the spinal cord, seen in childhood, and we are apt, again, too frequently to overlook it. It is allied to another form of disease which we may call disatrophy. I have under my care, at the Home for Crippled Children, a girl, aged eleven years, in whom there is marked muscular disatrophy; there is secondary affection of the joint at the knee and ankle, and there is scoliosis. While not a typical case of Freidrich's ataxia, it is closely allied to it. There is probably some change in the tissue of the spinal cord. The photograph of the case shows the deformity at the knee and ankle, but even while lying in bed, the twisting of the knee can be seen.

The last form of nervous disease which is confounded with scoliosis is shown by this photograph; the case had been under the care of a surgeon. When I went on duty at the Methodist Hospital, I found this women with the affection of her knees; the surgeon had tapped them. As the case did not seem to progress, it was turned over to the Medical Wards. I was struck by the peculiar deformity of the hand which neurologists call "main en-griffe." There was complete atrophy of the shoulder girdle. There was marked scoliosis. In short, the woman had muscular atrophy affecting the shoulders, arms and hands, with spastic symptoms in the legs, and with scoliosis and arthropathies. There were no sensory symptoms. The case was doubtless allied to syringomelia. It is interesting to note that it had been regarded and treated as a surgical case.

A number of hypotheses could be advanced to account for scoliosis. One observer says that all cases of scoliosis are allied to arthropathies; for instance, it is identical in the joints of the spine with arthropathies in the knee. Roth says it is due to muscular atrophy. Another hypothesis is that they are distinct trophic lesions, something like progressive atrophy.

When a case is of nervous origin, the scoliosis, to a certain extent, is an evidence of Nature's effort to put the diseased spine in a better position. I never saw a case which would tolerate an apparatus. Most of the cases suffer great pain if attempt is made to straighten the spine. I recently admitted to my ward in the Philadelphia Hospital a young woman affected very similar to some cases already mentioned; there is marked progressive muscular atrophy. She could not bear a brace of any sort. My remarks are entirely from the standpoint of a neurologist; I say nothing about the condition associated with empyema.

DISCUSSION.

DR. C. K. MILLS: I have had two cases of syringomyelia in which syinal curvature was was present. The cases of degenerative disease, and syringomelia in adults, are not the ones most likely to show deformities, but these occur most frequently in Freidrich's ataxa and the affection closely to it, pathologically, which show themselves early in life; but even in adults lateral curvatures do take place. I believe with Dr. Lloyd that little can be done with apparatus. In many other degenerative embryonal diseases, which are due to arrested development, my experience teaches me that little can be done either by operation or by apparatus, especially for the porencephalous cases. In spastic cases, either unliaterial or bilateral, some advantage can be gained as to pssition, but nothing more.

DR. G. G. DAVIS: The orthopædist ought not to be too strictly called to account, because I think they would not put on an apparatus for an advanced case of pure nervous disease, except as a palliative measure. Much can be done by apparatus and it depends upon the nature of the case greatly. If an apparatus will give any additional comfort to the patient, it is oftentimes advisable to order it. In regard to the cases referred to by Dr. Lloyd: in Freidrich's ataxia, a light brace might aid in supporting the body, and in Charcot's joints, a mechanical appliance does for a time support, and gives at least some slight relief, which is more than can be promised by medical treatment. I believe in the necessity for recognition of the points of a case, but I do not think that the application of apparatus is always useless.

Dr. J. Hendrie Lloyd: I should like to ask Dr. Davis if he would put an apparatus upon a Charcot joint. It is a matter of interest to me as a surgical question, and I should like to hear it discussed. I think, in these cases, the surgeon sometimes does not recognize the exact nature of the difficulty. I know of one case, however, in which a surgeon operated on a spinal arthropathy, the exact nature of which he did not recognize, and in which marked benefit resulted from the operation.

---

TORTICOLLIS.

DR. C. K. MILLS: The patient shown here to-night came to the Polyclinic Hospital

last week. I have not full notes of the case, but the history is as follows: The man is thirty years of age, a painter by trade. The difficulty started slowly; at first he experienced trouble in holding his head still. When reading a paper, in spite of everything he could do, his head would slowly turn to the left. He has no pain, but this has persisted and is slowly growing worse. The case is one of a class somewhat common, and, as we all know, most difficult to help. I have had considerable experience in what is termed spastic torticollis, both of the tonic and cloric varieties; they are most obstinate and may resist treatment for years or forever. One case in particular occurs to me, a patient whom I showed at my clinic, and an account of which was reported in the University Medical Magazine. She has three surgical operations on the spinal accessory, and she had been burnt with a hot iron many times, but no help was obtained. I have brought this man here to-night to obtain suggestions as to treatment. I have seen cases get well, but it is an affection difficult to cure because we do not recognize the underlying anatomical conditions.

DR. J. HENDRIE LLOYD: It is my opinion that torticollis involves a problem which we do not all understand. Prof. Ferrier and Mr. Horsley advanced the theory of a localizing torticollis centre; at that time we were ready to localize anything and everything. But certainly we do not understand the condition.

---

A paper on "The Treatment of Scoliosis by Free Movements and Apparatus," was next read by Dr. Randolph Fairies, in which he held that as the deformity is due to the concerted action of certain muscles or groups of muscles, therefore these should be kept inactive until their antagonists have been developed by means of exercises and gymnastic apparatus, sufficiently, to counteract the power exerted by the former ones. Also that the deformity, being compound, should be corrected in the same order as it occurred, that is, the rotation is first corrected, then the lateral curvature.

DR. WM. J. TAYLOR: I regret that I was not present at the reading of Dr. Faries' paper, as I am particularly interested in the treatment of spinal curvature by gymnastic exercises. I am glad to say, however, that such portion of the paper as I had the pleasure of listening to meets my views entirely. But, for the reason already given, I am prevented from discussing the paper intelligently.

DR. C. K. MILLS: I quite agree with Dr. Faries as to his method of treating spinal curvatures, but the difficulties in the way are great. Little can be done in this direction until the colleges set the example, and until, in connection with every hospital, a room is set apart for this purpose and is put in charge of a competent assistant, who can carry on the work year after year.

It is essential that we should impress upon ourselves and our patients that this treatment should be carried out systematically for two or three years if necessary. Great steps in advance will be made when the teaching institutions lead the way. One of the tendencies of modern medicine is in this direction, and steps should be taken immediately to further and further advance the treatment.

DR. G. G. DAVIS: Lateral curvature is a subject much considered by the orthopædic surgeon, and for it, much good can be done by gymnastics. There are two classes of such cases. In the mild ones, where the muscles are at fault, and the spine itself comparatively healthy, therapeutic gymnastics are of no service, But there is another class in which the pathological process is more profound and in which the bone and ligamentous tissues are likewise affected, and as the spine is the organ for keeping the body erect, the simple weight of the body which is supported by the spine will tend to cause curvature of it, and the tendency to distortion is increased by the efforts of the muscles on both sides of the spine. I believe that where this condition exists, the spinal column will give way and deformity will occur rapidly; in these cases exercise is of little or no service. I believe that there are cases of lateral curvature which might be termed malignant. The deformity goes on increasing, and in spite of most careful treatment, the patient rapidly grows worse.

DR. RANDOLPH FARIES: The most essential point is the fact that we are ignorant of the compound action of the forces which are used. It is quite true that when one set of muscles is weakened, the corresponding set is strengthened and rotation takes place, after which deformity ensues; but just what forces are used, we do not know, and it is just this which seems to me the true scientific basis of the study of this condition. If this could be determined, we should get at the rational method of treatment. The body of a vertebra may be made stretched by action, just as, by action, we make the tissues surrounding it more elastic. To my knowledge there is no medical book published which treats of the compound action of muscular force. Moreover, this seems to me the logical treatment of the disease, and until we treat scoliosis by the above method, we are doing so empirically.

### Puerperal Sepsis; Its Prophylaxis and Treatment.

Dr. Robert A. Murray, read a paper with this title. Antisepsis during labor, he said, was believed to be as necessary as in surgery. Three antiseptics could be managed easily—corrosive sublimate, carbolic acid and creolin. The prophylaxis should begin with a bath and a change of clothing. The vulva especially should be cleansed carefully. A new rubber cloth should be spread over a clean sheet, and over the rubber there should be a draw-sheet. The importance of an enema should not be forgotten. A vaginal injection of a 1-to-3,000 solution of corrosive sublimate or of a two-per-cent. solution of creolin should be given before labor, but usually not after it. Creolin was to be preferred to corrosive sublimate, because it was something of a lubricant, while corrosive sublimate was distinctly astringent, and so facilitated laceration. An antiseptic pad and napkin should be applied, and never removed except for examination, which should not be more frequent than was actually necessary. The physician's hand should be scrubbed thoroughly and immersed in a 2-to-2,000 solution of corrosive sublimate or a two-per-cent. solution of creolin. The antiseptic pad should be applied again after the birth of the child and before the expulsion of the placenta. Retained membranes and pieces of placenta should be removed at once by the aseptic hand, and then an intra-uterine douche should be given. Fluid extract of ergot, in half-drachm or drachm doses, was to be recommended in the majority of cases. After urination an antiseptic solution should be applied. When there was a bad odor to the discharge a vaginal douche was to be ordered, but if the examining finger showed that the foul discharge came from the uterus, it must be thoroughly curetted and a single uterine douche given. In prolonged cases instruments were to be employed. The nurse should never be allowed to examine a patient. In case of sepsis, the same general plan of antisepsis should be followed, but the vagina ought to be inspected so that the diphtheritic membrane might not be carried into the uterus.—*N. Y. Med. Jour.*

### The Therapeutic Effects of Hot Baths.

Topp (*Therap. Monatsh.*, January-February, 1894), with the view of testing the effects of hot baths, performed a number of experiments on himself, with the following results. In the first place, the articles in the daily diet were carefully weighed and compared with the elimination of nitrogenous compounds. On the first and second occasions the anthor remained for a quarter of an hour in a bath at temperature of 115° to 116° C. The body temperature at the same time rose to 105° C. In spite of the perspiration produced the amount of urine passed during the ensuing twenty-four hours was increased, and more particularly the absolute weight of nitrogenous material. The body temperature sank gradually to the normal. For practical purposes three to four baths daily, at a temperature of 105° to 109°, are recommended when the indiqidual can remain in the water about 40 to 45 minutes, and when the beneficial effects are even more marked. The author therefore agrees with Baelz in considering hot baths in the above form indicated in cases of capillary bronchitis and lobular pneumonia · also in rheumatism, nephritis, exudations, obstructive dysmenorrhœa, etc., but contra-indicated in cardiac affections.—*British Med. Iour.*

### Rheumatism, Acute.

℞ Sodii salicylat..... 3viss
Aquae ..... 3i
Syr. tolutan, q. s..... 3iij
M. Sig.—Teaspoonful every two hours.

### Chloroform in Lead Colic.

Dr. F. MacFarlan, of New York (*The American Therapist*, April), remarks that he has had great success in the treatment of lead colic by the internal administration of chloroform. He gives ten minims every half hour, if required. The pain is speedily relieved by the drug. The other features of the treatment go on in the usual way, such as the use of potassium, iodide and laxatives. The chloroform is decidedly more effective in easing the pain than morphia, as a trial of the two remedies will abundantly prove. The speedier relief also favours a quicker and more satisfactory recovery.

### Growing Pains.

Parents have for a long time handed down to succeeding generations the tradition that pains in the limbs of a growing child are a necessary evil and not associated with any one disease, and physicians have generally encouraged this theory: but Dr. P. B. Bennie, in the *Archives of Pediatrics*, has completely ignored this idea and argues that all pains in growing children are due to some specific cause, such as myalgia from fatigue, rheumatism, disease of the joints, fevers, adenitis, etc., in which rapid growth is only a concomitant and not a causal constituent. He says in conclusion: "This malady, 'growing pains,' with its frequent concomitant, growing fever, like its congener, disorders of dentition, vanishing from the realm of pathology through that of fancy, is fast sinking into oblivion in the medical literature of the past. As a separate morbid entity it exists now principally as an article of faith. The complaint still maintains, however, a strong hold of the lay mind and forms an extremely common lay diagnosis which is often the cause of much suffering and even death through leading to the neglect of curative measures at a time when they are most effective. But the day is approaching when its grip will be loosened, for the history of medical superstitions shows that they begin to wane first among the thinkers in the profession, and finally disappear among the uneducated laity and "growing pains" will be found to be no exception to the rule."—*Maryland Med. Jour.*

### Three Kinds of Head Pains.

Dr. Dana, New York (in *The Post-Graduate* for April), calls attention to the three following varieties of head pains : (1) Migraine, which is constitutional; (2) headaches of a diffuse kind and are due to overwork, eye-strain, etc., and (3) neuralgia. Migraine patients suffer most in damp weather and in the spring. Neuralgias of the head are of two forms (a) supra-orbital, infra-orbital and detail forms, (b) Tic douloureux. The first group of neuralgias is usually due to decayed teeth, or cold. The second form is rare, comes later in life, and oftener in men than women. It is extremely, obstinate, and may last for many years. Tic douloureux is frequently associated with obliterating arteritis. This gives rise to nerve anæmia and degeneration. Nitro-glycerine and aconite sometimes relieves, by acting upon the arteries, lessening their tension. Hypodermic injections of strychnine are often helpful.

## SURGERY.

### Guaiacol in the Treatment of Blennorrhagic Epididymitis.

At a recent meeting of the *Societe medicale des hopitaux*, of Paris, a report of which we find in the *Union Medicale* for April 10th, M. Balzer and M. Lacour stated that they had obtained excellent results in the treatment of blennorrhagic epididymitis with guaiacol. On the skin of the inguinal region, they said, pure guaiacol could be applied; on the scrotum it was better to employ an ointment of from two to five parts of guaiacol to thirty of vaseline. One of the first effects of the application of this ointment was a rather sharp burning, lasting for about ten minutes; then the patient felt a sensation of heat, and almost immediately the pain disappeared, at least for three or four hours, and sometimes it did not return. Ordinarily it was necessary to make two applications on the first day, but after the third day there was no longer any pain. The applications were then discontinued, for they did not seem to exert any very decided resolvent action upon the inflammatory infiltration of the epididymis. It was evident, the authors said, that guaiacol exerted a very clear and energetic effect upon the pain of the disease; moreover, it overcame certain of the general symptoms which were due to the pain, for example, sleeplessness. It gave rise to a slight erythema of the scrotum, followed by drying and exfoliation of the epidermis. The authors had treated twenty cases with guaiacol, and in all of them the results had been most favorable and very rapid.—*New York Medical Journal.*

### How Ought we to Treat Gonorrhœal Epididymitis.

Dr. Henri Picard (*La France Medicale*) answers this question by stating that there is, or has been, constipation for a few days. This requires a purgative to free the digestive canal, and will relieve the compression on the rectum, the prostate and the urethra. The drastics, and especially aloes, should not be ordered, but the salines or castor oil. If the constipation continues, use large enemata.

Rest, in the horizontal position, is the next point to attend to. Along with this a good support must be fitted to the testicle. This affords a great deal of relief; and permits the patient to turn in bed without pain, and, in sub-acute cases, to move around the room. Horand's support is the best. This support is made of a large piece of lozenge-shaped linen, split at the lateral angles, and lined with a thick layer of cotton wool, placed on vulcanized linen. By means of the angles this support can be fastened to the body, so as to hold the scrotum and testicles, and afford gentle pressure.

Demulcent drinks are of much value. They soothe the inflamed urethra, and render the urine less irritating. Linseed tea, infusion of violets, orange water, etc., are very good forms of drinks, and should be taken in large quantities.

A bath once or twice a day, or every other day, of the temperature of 95° F. is useful. These baths require to be prolonged. There is not much benefit from them unless kept up for some time. They calm the pain and favor sleep.

For the pain and tenderness the best remedy is salicylate of soda in doses of

three to four grms. daily. Antipyrine has been used with advantage; and the anemone pulsatilla has been found very beneficial in allaying pain and swelling.

When there is much swelling, redness of the skin, and the scrotum and testicles are very painful and tender, half a dozen leeches should be applied along the cord. If the condition of the tissues is serious, even a dozen may be used.

Later on, iodide of potash ought to be employed to remove the induration and enlargement that has been left by the disease. Mercurial strapping or ointment, may also be employed for these conditions. In spite of all efforts it is sometimes impossible to restore the testicle and epididymis to their normal size. The vas deferens is sometimes obliterated and the seminal fluid cannot make its way from the corresponding testicle.

## OBSTETRICS.

### Single Ligation of the Cord in Obstetric Practice.

According to the *Boston Med. and Surg. Jour.* of March 1, 1894, Nguyen Khac Can bases his opinion of the superiority of a single ligature upon his observation that out of sixty-eight cases of labor with double ligature of the cord, there were four cases of retention of the placenta, and out of one hundred and forty-six cases with single ligature, only two cases of retention. The duration of the third stage with the double ligature averaged sixty-four minutes, while with the single it was but twenty-seven minutes.

The author believes that a rapid diminution in the size of the placenta, due to the free escape of the intra-placental blood, favors retro-placental hemorrhage and consequent complete separation of the placenta, and that it further lessens the obstacle to its escape from the uterus and vagina by the resulting decrease in size. He recommends that double ligature of the cord should be reserved for cases of twin pregnancy. While we think that there is a question as to the correctness of the author's reasoning on the first point, there can be no doubt as to the advantage of diminishing the size of any body which is to pass the os uteri, and we have ourselves noticed a greater ease of delivery of the placenta in cases in which but one ligature had been applied.

The suggestion of Nguyen Khac Can is certainly of value. It should be easy to prevent untidiness by catching all the intraplacental blood in a suitable basin, but the determination not to check intraplacental hemorrhage, of course, implies a careful palpation of the uterus before the cord is cut, and an absolutely positive elimination of the possibility of a twin pregnancy.—*Therap. Gazette.*

### Chronic Headache.

## ARMY AND NAVY.

CHANGES IN THE U. S. ARMY FROM JUNE 10, 1894, to JUNE 23, 1894.

Leave of absence for one month on surgeon's certificate of disability, with permission to apply to the proper authority for an extension of three months, is granted Major Joseph R. Gibson, surgeon, Fort Snelling.

PROMOTIONS.

First Lieutenants Philip G. Wales and Benjamin L. TenEyck, Assistant Surgeons, to be Assistant Surgeons with the rank of captain, June 7, 1894, after five years' service in conformity with the act of June 23, 1894.

First Lieutenant Deane C. Howard, Assistant Surgeon, is relieved from duty at Fort Buford, North Dakota, and will report in person to the commanding officer, Fort Snelling, Minn., for duty at that station.

The leave of absence on surgeon's certificate of disability granted Major Joseph R. Gibson, Surgeon, is extended three months on surgeon's certificate of disability.

Leave of absence for one month, on surgeon's certificate of disability, is granted First Lieutenant Frank T. Meriwether, Assistant Surgeon, with permission to leave the limits of the Department.

Major James C. Merrill, Surgeon, is relieved from duty in the office of the Surgeon-General, to take effect July 1, 1894, and ordered to report in person to the commanding officer, Fort Sherman, Idaho, for duty at that station.

Leave of absence for three months to take effect July 1, 1894, is granted Major James C. Merrill, Surgeon.

## NEWS AND MISCELLANY.

### New Hospital Managers.

The Governor of New Jersey recently appointed the following gentlemen as members of the new Board of Managers of the State hospitals: Mr. George Richards, Dover; Dr. Romeo F. Chabert, Hoboken; Rev. Dr. J. M. Buckley, Morristown; Mr. George B. Jenkinson, Newark; Mr. Patrick Farrelly, Morristown; Mr. Lewis Parker, Trenton; Mr. Charles E. Green, Trenton; Mr. John Howe, Monmouth. The new Board appears to be made up of the right material. The Rev. Dr. Buckley, editor of the *Christian Advocate*, of this city, is known to be a great friend of the insane, and for more than twenty-five years has manifested a warm interest in bettering their condition everywhere. With the advent of the new Board into power, partisan considerations will undoubtedly cease to pertain in the State hospitals of New Jersey. The present medical officers of these hospitals, who have so vigorously endeavored to keep the great charitable institutions under their charge beyond the grasp of political despoilers, ought to feel encouraged at seeing the dawn of what appears to be a new era.—*Medical Record.*

George G. Shoemaker, M. D., died at his home at Knox, Pa., on May 20th, 1894. Age 38 years.
